*The Doctor's Books*,<sup>6</sup> by Mr. A. P. BERTWISTLE, is a short description of a system of book-keeping designed to meet the needs of medical practitioners and dentists and to avoid the employment of special books or cards. The case-book, on the loose-leaf system, enables a systematic record of early symptoms to be made and the past history and the previous treatment of the patient to be quickly ascertained, while the cash book combines the merits of completeness and absence of complication.

*The Pharmacopoeia of University College Hospital* has been revised, and the new edition<sup>7</sup> contains eighteen new formulae. As in former editions, both metric equivalents and the imperial weights and measures are supplied. A table of food values has been added, and the section of pathological data has been revised and condensed. Prescriptions for children are listed separately. The volume is interleaved, and is of convenient size for the pocket.

<sup>5</sup> *A Pocket Guide Book to Medical Life Assurance*. Compiled by Jehangir J. Cursetji, M.D., L.R.C.P., L.R.C.S., L.M. and S. F.R.S.M.Lond. Bombay: The Times Press. (4), x 74, pp. 65 + xvii; 1 plate.)

<sup>6</sup> *The Doctor's Books*. By A. P. Bertwistle, M.B., Ch.B., F.R.C.S.E. London: J. Bale, Sons, and Danielsson, Ltd. 1926. (6 x 4½, pp. 25; illustrated. 1s. 6d. net.)

<sup>7</sup> *Pharmacopoeia of the University College Hospital, 1926*. Published by authority of the Medical Committee. Edited by Charles H. Hampshire, B.Sc.Lond., F.J.C. London: J. Bale, Sons, and Danielsson, Ltd. 1926. (3½ x 6½, pp. 99. 4s. net.)

Dr. W. B. BLANTON has written *A Manual of Normal Physical Signs*<sup>8</sup> in order to assist students who have a difficulty in obtaining normal standards of comparison of the physical signs in health and disease. The information is set out in notebook form, which renders it more useful for reference than for continuous reading. The subject-matter is classified so that the various forms of examination and the methods of investigating special organs and systems can be seen in detail at a glance.

A series of lectures under the auspices of the People's League of Health has been published under the title of *The Importance of Diet in Relation to Health*.<sup>9</sup> Dr. Leonard Hill deals with the general subject of diet, Sir D'Arcy Power considers food from the historical and geographical standpoints, and Professor Halliburton writes on vitamins and diseases caused by badly chosen diet. The principles of infant feeding are set out by Dr. H. Scurfield, Dr. M. J. Rowlands treats of the subjects of the feeding and breeding of cattle in relation to the public health, and Professor W. E. Dixon contributes an article on food preservation and adulteration.

<sup>8</sup> *A Manual of Normal Physical Signs*. By Wyndham B. Blanton, B.A., M.A., M.D. London: H. Kimpton, 1926. (Post 8vo, pp. 215. 12s. net.)

<sup>9</sup> *The Importance of Diet in Relation to Health*. The People's League of Health Lectures. London: G. Routledge and Sons, Ltd. 1926. (Cr. 8vo, pp. xii + 136. 3s. 6d. net.)

#### THE HEALTH OF THE SEAMAN.

##### INTERNATIONAL RED CROSS CONFERENCE IN NORWAY.

IN 1924, at the third meeting of the general council of the League of Red Cross Societies in Paris, the Norwegian Red Cross Society put forward an international scheme for the promotion of the health and welfare of the sailor. The principle underlying this scheme was unanimously accepted by the other national Red Cross societies in the league, and the Norwegian Red Cross Society was given a mandate to work it out. The Norwegian Red Cross has elaborated it, and it was with a view to studying it in detail that the Norwegian Red Cross and the League of Red Cross Societies invited representatives of the national Red Cross societies of all maritime countries and certain other bodies, such as the International Labour Office, to meet in Norway in a conference which should assemble at Oslo on June 28th, and pay visits to Bergen and Trondhjem. The subjects set down for discussion were: (a) Educational propaganda on board ship by posters, pamphlets, and in other ways; (b) the improvement of existing manuals on hygiene for seamen or the publication of new ones; (c) the establishment of Red Cross medical stations for seamen; and (d) the plans for a standard up-to-date medicine chest.

The delegates from Great Britain were: Mr. L. Bowden, representing the British Social Hygiene Council; Colonel L. W. Harrison, representing the Ministry of Health; Dr. F. N. Kay Menzies, representing the London County Council, the British Red Cross Society, and the Order of the Hospital of St. John of Jerusalem; Mrs. Neville Rolfe, representing the British Social Hygiene Council; and Mr. Murray-Williams, representing the British Red Cross Society. The League of Red Cross Societies was represented by Dr. F. Humbert and Dr. C. Lillingston; the League of Nations by Professor T. Madsen and Dr. Norman White; the International Labour Office by Dr. Butler and Mr. Sture Thorsson; and the International Red Cross Committee by Surgeon Commander L. F. Cope, R.N. The countries represented, in addition to Great Britain, were: China, Costa Rica, Denmark, Finland, France, Germany, Holland, Italy, Japan, Spain, Sweden, and the United States of America.

The conference was formally opened by the King of Norway, in the presence of a large and representative gathering, in the hall of the university in Oslo. Dr. Engelsen of the Norwegian Red Cross presented to King Haakon the first copy of the medical manual prepared by an editorial board of medical men under the auspices of the Norwegian Red Cross, and a paper was read on certain hygiene problems in the merchant service by Dr. Ustvedt, chief medical officer of the Ullevaal Hospital. The following days were devoted to discussions, and it was soon found that the problem of establishing medical stations under the Red Cross for seamen throughout the world engrossed the attention of the delegates almost to

the exclusion of the other subjects on the agenda. Though appreciation was expressed for the work of the Norwegian Red Cross in preparing a medical manual and medicine chest, both of which might become the basis of an international standard, it was realized that they would have to be more carefully studied than the time at the disposal of the conference would allow, and they were referred to a standing committee for further study.

The problem of medical stations was thrashed out very thoroughly. The original plan of Dr. Engelsen of the Norwegian Red Cross was for one doctor in each seaport town to put his surgery at the service of the Red Cross, charging his usual fees when he treated a sailor himself, and acting merely as a clearing station for those he sent on to specialists or hospitals. He had made arrangements with twenty-one doctors in twenty-one Norwegian ports to put the Red Cross sign outside their surgeries. His hope was that similar stations would be organized throughout the world, and that the captain of every merchant vessel should be provided with the addresses of every Red Cross doctor on his route, so that he would have no difficulty in knowing where to send a sick sailor when his ship reached port. In this connexion it may be well to quote some passages from a paper read at the conference by Dr. J  rgen Berner, Secretary-General of the Norwegian Medical Association. It should be noted that the medical officer of health of most Norwegian ports is also a general practitioner. Dr. Berner said:

"Only by establishing permanent medical stations whose locality is known beforehand to the seaman is it possible to give him effective aid. The medical officer of health of the port is already responsible for the supervision of the hygiene of the ships in port and for all measures concerning infectious and epidemic diseases. When the medical officer of health cannot, or will not, undertake this work, another doctor may be appointed after consultation with the Norwegian Medical Association, the rate of remuneration being that of the association in this locality for the time being. It is inevitable that the solution of the various social medical problems and the safeguarding of the economic interests of the medical profession must sometimes, to a certain extent, clash. This may happen especially in an arrangement limiting to a certain extent the free choice of a doctor. In this connexion the establishment of permanent medical stations for seamen may be criticized. The principle of free choice of doctor—that is, that every patient shall be free to choose the doctor he wants and in whom he has confidence—has successfully been maintained by the Norwegian Medical Association during the past twenty-five years in its negotiations with insurance societies and others. Both doctors and patients consider this arrangement to be ideal. We have found it necessary to abandon this principle in the matter we are now dealing with, because the Norwegian Medical Association has been unable to indicate any other solution for this problem, which is of so great importance that the claims of the individual must give place to the good of all. I am pleased to say that the executive's attitude in this matter has not been criticized by any of the members of the association. On behalf of the Norwegian Medical Association I beg to wish the Red Cross every success in its task, and to express the hope that it will soon see its plan realized throughout the world."

So much for the attitude of the Norwegian Medical Association, which has been described as "the most powerful trade union in Norway." After Dr. Berner's paper, small and large groups of delegates attempted during the rest of the conference to thrash out the difficult problems arising. It was maintained by more than one delegate that Dr. Engelsen's plan entailed a monopoly, and that the Red Cross Society which appointed one doctor in a port to act as its special medical officer would arouse the ill will of his colleagues. An alternative scheme suggested was that the Red Cross should establish an information bureau in each port where information would be given as to where appropriate medical advice and treatment could be secured, where letters could be received, and information obtained as to local recreational and social facilities, and where sleeping accommodation could be procured. It was the general opinion of the conference that the Norwegian Red Cross had focused attention on a state of affairs which might otherwise have continued to be neglected indefinitely. It had demonstrated the existence of a big gap in the welfare work for seamen, and had traced the broad lines to be followed to fill it. It was also the opinion of most of the delegates that each maritime country would have to work out its own scheme for Red Cross medical stations for seamen, but that individual national differences would not prevent the system becoming

unified throughout the world under the Red Cross. A suggestion which received much support was that each delegate, on returning to his own country, should communicate with the national medical association thereof with a view to its putting the health and welfare of the seamen on the programme of its annual meeting in the summer of 1927. In the case of Great Britain Dr. Lillingston undertook to approach the British Medical Association. If this plan can be carried out in its entirety, the chief medical associations of the world should be able to provide in 1927 a vast amount of information which should be of great value to the League of Red Cross Societies, the International Labour Office, and other bodies, in co-ordinating an international movement for the health and general welfare of the sailor. The following preamble, resolutions, and appendix were unanimously adopted by the conference.

The conference desires to place on record its great appreciation of the initiative taken by the Norwegian Red Cross in the organization of the conference, and of the work done by that society in establishing medical stations in Norwegian ports, and preparing a medicine chest and manual, and also its great appreciation of the general progress which has taken place in recent years in the provision made for the health and welfare of merchant seamen in certain ports.

From evidence placed before the conference it appears that there is in nearly all countries a need for further development in activity on behalf of the general health and welfare of seamen. During the discussions emphasis has been laid on the special dangers caused by tuberculosis, venereal diseases, and tropical diseases.

Even in those ports in which medical provision for seamen is adequate it often happens that foreign seamen find it difficult to ascertain where treatment and advice can best be obtained. A central bureau, or bureaus, under a local seamen's welfare committee, at which seamen of all nationalities could obtain information regarding such matters, as well as information regarding social and recreational facilities available, would be of the greatest benefit. Such bureaus could further be of great use as addresses to which letters from home for the seamen might be sent. In certain circumstances—for example, in the smaller ports—medical stations and clinics for seamen might with advantage be attached to such bureaus.

#### Resolutions.

In view of the above considerations the conference recommends:

- (1) That bureaus for furthering the health and general welfare of seamen be established in seaports throughout the world in close liaison with, and as a further development of, such national and international action in this field as has already been taken.
- (2) That each bureau be placed in a prominent position at the waterside. The chief function of these bureaus would be to furnish (a) treatment or information as to where appropriate medical advice and treatment can be secured, (b) postal facilities as outlined above, and (c) information as to the local recreational and social facilities and sleeping accommodation.
- (3) That such seamen's bureaus should be distinguished by a common badge of world-wide application.
- (4) That the League of Red Cross Societies should invite the national Red Cross societies of maritime countries in the first instance to take the initiative in the establishment of these bureaus in consultation with shipping and other organizations interested.
- (5) That the shipping interests and the seamen's organizations in each country should be invited to promote or to assist in promoting recreational facilities and welfare work among seamen. The provision of recreation and social amenities is recognized as of equal importance in maintaining the health of seamen as efficient medical treatment.
- (6) That the League of Red Cross Societies should invite the International Labour Office, the Health Organization of the League of Nations, and other international organizations concerned, to co-operate in appointing a standing committee on the welfare of seamen, this committee to arrange for expert investigation of: (a) Facilities for the medical treatment of seamen—for example, standardization of ships' medicine chests; medical manuals; a wireless code for medical consultations at sea; education of ships' officers in first aid and in the use of medicine chests; health propaganda among seamen, etc. (b) Welfare conditions on board and in port; the provision of recreational facilities for seamen of all nationalities; social conditions in the ports; ships' libraries, films, etc.
- (7) That the League of Red Cross Societies publish the transactions of the conference.

The conference expresses: (a) Its high admiration for the enterprise of the Norwegian Red Cross Society in publishing a medical manual for the use of officers of the Norwegian merchant service, and particularly for the skill which Dr. Engelsen and his collaborators have displayed in its preparation. This manual, a copy of which has been presented to each delegate, should be studied in each country represented; it will be of great assistance to those responsible for the preparation of similar works in other languages. (b) Its gratitude to the League of Red Cross Societies and its secretariat for their assistance, mentioning especially its director-general, Sir Claude Hill.

SATURDAY, JULY 31st, 1926.

## THE NOTTINGHAM MEETING.

ANOTHER Annual Meeting of the British Medical Association has come and gone, but the crowded events of the Nottingham week remain with us as a pleasant memory. When our last issue went to press the meeting was still in progress, and we were only able to give a full account of some of the earlier proceedings. This week we publish further reports and descriptive notes. The written word is too often inadequate, but it may refresh the memory of those who took part and convey some idea of the meeting to others less fortunate; it is a means also of expressing gratitude to our hosts for all they did to bring about success. What, then, are the outstanding impressions that remain? One is, we think, a sense of the smooth working of well laid plans, matured and carried out by a band of brothers; the other is appreciation of the kindness and courtesy of all classes, for the inhabitants were at one with the local profession in demonstrating to the British Medical Association that Nottingham, both city and county, is another word for hospitality.

The personality of the President is always a considerable factor in the success of an Annual Meeting. Last year at Bath this could be felt plainly enough, even though Dr. F. G. Thomson himself was on a bed of sickness and had to address his guests through the mouths of friends; his presence in good health at Nottingham last week was very welcome to all the members. More fortunate than his predecessor, Mr. R. G. Hogarth was able to take an active part in his own meeting, and it is not too much to say that from first to last his individuality spread its warmth over the whole proceedings. Mr. Hogarth's spirit never seemed to flag, and throughout an arduous week he managed to say the right word, in public as in private, with an air of charming informality that endeared him to all. Of the many loyal helpers, whose invaluable work the President acknowledged at the Annual Dinner, and whose names are mentioned elsewhere, we can single out only one for praise in this place. For months—and indeed, it is said, for years—Mr. A. M. Webber had planned and worked behind the scenes; during the meeting he was here, there, and everywhere, giving himself without stint to all comers; and now it is triumphantly over we hope he is satisfied with the result of his unselfish labours.

We have indicated that the Nottingham meeting of 1926 was a success, and have tried to show why. This is not the time to attempt any comprehensive review of a large and many-sided meeting, for the event is too near; but in a brief backward glance a few leading features may be remarked. First we note that 1,086 members registered. This figure takes no account of the great number of wives and daughters whom Nottingham lavishly entertained by day and by night, nor of those members who rushed into University College to hear a paper discussed and

left Nottingham without recording their names. Those who took part in the scientific work included an unusually large number of distinguished colleagues from Canada, the United States, and the Continent; the Anaesthetics Section in particular, under the presidency of Dr. Samuel Johnston of Toronto, was attended by many visitors from America, and had the character of an international conference. As might be expected in so large a gathering, the attendance in the less specialized sections was very good, and a number of profitable discussions on topics of wide interest were followed by audiences drawn from all branches of practice. In order that others may gain an early idea of the course of the scientific and clinical proceedings, both general and special, we print this week the first instalment of a series of notes on the daily work of the Sections. The debate on food deficiency conditions in the Section of Public Health is reported in full at page 185. This and the brief summaries will be followed in due course by full reports of all the sessions. The morning papers and discussions were rounded off again this year by a number of afternoon demonstrations, and of these also we hope to provide some account. Most of the demonstrations were given in the annual Pathological Museum which had been organized mainly for this purpose. The specimens, photographs, and slides on view there attracted many visitors, who found the exhibits, illustrating recent advances in methods of diagnosis and treatment, highly instructive.

By the time the scientific Sections began their work the Annual Representative Meeting of the Association had run its usual four days' course under the able chairmanship of Dr. Brackenbury. Though the agenda paper was neither long nor contentious, as judged by recent years, a considerable volume of medico-political and administrative business had to be got through. The subjects under review arose directly, for the most part, out of the quiet and efficient work done in committees and subcommittees, and in the several departments at headquarters, during the past twelve months. The outcome of all these varied activities had already been set down in the Annual and Supplementary Reports of Council, which formed the groundwork of the representatives' deliberations. Reports on many uncontroversial matters came up for approval and were approved; but now and again the placid waters were ruffled, and the anglers from the newspaper press seem to have landed a few fish of moderate size. A full report of the proceedings of the first two days appeared in last week's SUPPLEMENT, and the conclusion of the Representative Meeting is recorded this week. These detailed reports, together with the informal commentaries printed in the JOURNAL under the heading of "Annual Meeting Notes," will, it is hoped, suffice to keep members in general acquainted with the business transacted this year by those who represent them in what is often styled the parliament of the medical profession.

As for the social side of the ninety-fourth Annual Meeting, a great deal might be written without exhausting the topic. We shall, however, try to give some slight notion of its varied character in the SUPPLEMENT. It is almost enough to say here that the functions of every kind were, by general consent, admirable. The entertainment by Buxton of the representatives and their womenfolk, during the week-end between business sessions, was a thing quite out of the ordinary. Many other pleasant trips to interesting places—ranging from cathedrals to coal-

mines—were provided during the week. The receptions by the President and by the Mayor at Nottingham Castle were as brilliant as that overworked adjective can be made to convey, and the speeches at the Annual Dinner were better and shorter than usual. A first-class concert was provided by the generous firm of Boots, and a succession of evening affairs, each with dancing into the small hours, ended with the ball given by the Nottingham Division. On the following day the members and their families scattered in all directions, some to distant parts of the empire, all taking with them the happiest recollections of the profession and the public of Nottingham.

### THE ROYAL COMMISSION ON LUNACY.

THE report of the Royal Commission on Lunacy and Mental Disorders issued on Wednesday last is an important document, with which we cannot pretend to deal critically to-day. It is important chiefly perhaps because it may confidently be expected to quicken the shifting of opinion from the fatalistic legal view to the rational and scientific. It was an obsession of the late Lord Halsbury that thousands of sane people were confined under certificates. He used the great influence his position gave him to imbue lunacy law with this idea, but it was an *a priori* view for which he had no adequate body of facts that would stand examination. The Royal Commission heard a good deal of evidence in support of this view, but did not accept it. While refraining from pronouncing judgement on individual cases the Commissioners say that in none of those brought before them "were they left in any doubt as to the propriety of the certification," and their conclusion is "that the evidence does not support the suggestion that the present safeguards against wrongful certification, if properly observed, are inadequate." The Commission is satisfied that at the present time instances of sane persons being wrongfully certified or improperly detained must be of the rarest occurrence. Attention is very properly drawn to another aspect of the matter, which is, that the public are entitled to be safeguarded against the presence in their midst of persons of unbalanced mind and dangerous tendencies. "Any properly conceived lunacy code," it is said, "must have regard to the rights of the public, who are entitled to its protection against risks attendant on failure to detain those who ought to be detained." Incidentally the Commissioners, after hearing evidence submitted to them and after visits to numerous institutions, express their definite opinion that, on the whole, patients are well cared for, and that there is no ground for the allegation that ill-usage is deliberately or systematically practised in mental institutions; where such incidents happen they are isolated occurrences.

It will be remembered that when the Royal Commission was set up in July, 1924, the British Medical Association appointed a Special Committee to consider possible modifications of the lunacy laws, to prepare evidence for submission on behalf of the Association to the Royal Commission, and to appoint witnesses to give evidence. The Committee prepared a memorandum, which was submitted to the Royal Commission at the beginning of 1925,<sup>1</sup> and evidence was given on behalf of the Association by a number of witnesses. This evidence, together with that given by other witnesses, was duly reported in our columns

from time to time. It is clear that the Royal Commission has given careful attention to the views expressed on behalf of the Association; it has in its recommendations made proposals for giving effect to the majority of them. This is only a general impression on a first perusal, and there are many matters of detail which must be carefully studied.

The Commissioners recommend that the lunacy code should be recast, so that the treatment of mental disorder should approximate as nearly to the treatment of physical ailments as is consistent with the special safeguards indispensable when the liberty of the subject is infringed. They have come to the conclusion that facilities for the treatment of voluntary boarders should be increased, particularly by their admission to public mental hospitals, and that early treatment should be encouraged by the provision of clinics. Certification, it is said, should be the last resort, and not necessarily preliminary to treatment; the procedure for certification should, therefore, be simplified, made uniform for private and rate-aided cases alike, and dissociated from the Poor Law. The report lays emphasis upon the need for extending facilities for the treatment of incipient insanity without certification. In the case of an involuntary patient it is advised that if there is a prognosis of early recovery facilities should be provided for treatment without certification for a period of one to six months under a provisional treatment order. When voluntary patients require full certification a reception order should be made on two medical certificates by a judicial authority consisting of specially selected justices, who should exercise their discretion under conditions to be prescribed by statute.

The report of the Commission contains a special section on research work and recommends that at the present stage each large mental institution should have a laboratory adequately equipped for routine examinations, and that higher research work should be conducted in a limited number of central laboratories serving a county area or group of counties. Such laboratories, it is thought, might be provided either by local authorities or voluntary agencies, or by the co-operation of both, and should be associated whenever possible with a university. In this connexion we may note the recommendation that while the medical officer in charge of the mental institution should be the ultimate authority on all matters medical and administrative, he should be relieved of administrative details to a greater extent than is at present the case. He should retain a decisive voice in all matters affecting the care and treatment of patients, but should be able to devote the greater part of his time to the medical questions, which are more immediately his concern. It is advised also that the present medical staffs of some institutions ought to be increased, and in all instances be large enough to make it possible to allow facilities for assistant medical officers to be given study leave. It is said that in order to attract and retain in the service suitable assistant medical officers the financial prospects ought to be improved.

The report of the Commission makes reference to the reluctance of medical practitioners to be involved in the certification of the insane, owing to the liability to actions at law. The Commission recommends "that for the more effective protection of medical men and others in the bona fide discharge of their duties under the Act, Section 330 should be so amended as to provide that any such person shall not be liable to civil or criminal proceedings unless he has acted

<sup>1</sup> SUPPLEMENT, January 17th, 1925, p. 29.

with bad faith or without reasonable care," and that subject to this qualification "any proceedings taken against such person shall be stayed upon a summary application to the High Court, or a judge in chambers." The Association in its memorandum claimed for medical practitioners who sign medical certificates under the Lunacy Act the immunities granted to witnesses in courts of law; it insisted that the medical certificate should be given very definitely the status of evidence, and that therefore the protection witnesses in courts of law are entitled to receive should be extended to the practitioner who signs a certificate under the lunacy laws. We do not see that the Commission has made any definite reference to the point thus made by the Association, but possibly the words above quoted may be considered partly to satisfy the point.

One of the sections of the British Medical Association's memorandum dealt with the value of variety in the type of institution for the reception of mental cases. There exists, it was said, a desire in the community that it should be possible to treat suitable patients otherwise than in public institutions, and that if the existing veto on the setting up of more licensed houses or the extension of those now existing were to result in the diminution or inadequacy of this provision, it might be necessary to repeal the veto or to provide extended facilities for the treatment of patients in small numbers in private hands under proper safeguards. Upon this point the Royal Commission is divided; some of its members considered that licensed houses should be abolished as soon as alternative accommodation can be provided either at registered hospitals or by local authorities; others were of opinion that licensed houses should be continued, but on a new footing, under conditions including stricter administrative and financial supervision, and with power to the Board of Control to issue new licences.

With regard to general administration it is advised that the county councils or county borough councils should be made responsible for providing accommodation and maintaining therein persons who, through mental disability, must be detained under care at the public expense. The cost of maintenance, it is advised, should be transferred from the poor rate to the county or borough rate, and it is considered that in providing a lunacy service on the lines envisaged in the report it is essential that local authorities should be assisted by an Exchequer grant, subject to the provision that all institutions should be supervised by the Board of Control. The work done by that Board is highly praised, but it is recognized that it is handicapped by certain factors beyond its control. One is that in order to effect economies the number of its members has been so much reduced that it is not in a position to discharge the duties imposed upon it by statute. To meet this difficulty it is recommended that the Board should consist of four or five commissioners only, and that most of the visitation should be done by a body of fifteen assistant commissioners attached to headquarters.

Taking a broad but necessarily somewhat hasty view of the report, it seems that it is a step forward, that the Royal Commissioners have approached the difficult subject with which they had to deal in an admirable temper and have made many suggestions which, if carried into effect, would advance the study of psychiatry, tend to the prevention of confirmed mental disorder, and contribute to the welfare both of patients and of the public.

## ANTIGENS FOR THERAPEUTIC IMMUNIZATION.

THE paper by Sir Thomas Horder and Dr. Ferry published this week (p. 177) describes a novel method of preparing vaccines for which promising results are claimed. Those whose business it is to manufacture vaccines belong usually to one of two schools: either they believe in the dead but otherwise unaltered bacterium, or else they believe in predigesting it or robbing it of its sting. The latter group of experimentalists has been responsible for "defatted," "detoxicated," "trypsinized," and many other modified vaccines which have enjoyed a degree of popularity almost exactly commensurate with the time and energy spent on their advertisement. When one considers what other elements in the microbe are worthy of a trial from the hands of the immunologist there does not seem much left, for it is no exaggeration to say that laboratory workers are to be found in almost every university town of this country and the Continent who look back on ten or twenty years spent in the attempt to isolate and identify antigen and antibody. Do the experiments recorded by Horder and Ferry suggest that the ideal antigen for which these patient research workers have been seeking has been allowed to run to waste down the laboratory drain?

The investigations now summarized have been in progress since 1921; their purpose was to determine the practical immunizing value of bacterial antigens prepared after various methods, in the hope that a substance would be found more nearly fulfilling the requirements of an ideal antigen than any at present in use. Broth cultures of the typhoid bacillus, the colon bacillus, the pneumococcus, and other bacteria of the (so-called) endotoxin-producing class were first used, and the early results showed that the antigen properties of the filtrate were higher than anticipated. The inference was drawn that the antigenic substances must be more or less loosely bound up with the bacterial cell and reside in the bacterial surface or ectoplasm rather than in the endoplasm. In the next stage a centrifuge instead of porcelain filters was used to wash the bacteria and the fluid yielded was found to be highly antigenic, while the washed bacilli were very low in antigenic content. This method of washing extracted the antigenic substance from the bacteria, while the toxic principles were left behind. The name "ectoantigen" is suggested for such products, and for products prepared in such a manner as to contain only this ectoantigen the term "immunogens" is proposed. Animal experiments were in all cases favourable to the theory. The conclusion then was that these washings more nearly approach the ideal antigen than any others which had been examined. They are in aqueous solution, low in protein content, high in antigenic properties, and practically non-toxic. During the last two years the immunogens have been tested clinically by a considerable number of observers, and promising reports have been received in connexion especially with streptococcal, pneumococcal, and gonococcal infections; in the experience of most of those who had tried them, these products have not caused reactions of an undesirable kind.

There are only two satisfactory methods of investigating the value to practical human medicine of any method of preparing vaccines. One is the virulence test on animals, and the other is clinical observation on human patients. The report by Horder

and Ferry does not make it quite clear by what standards they judged antigenic capacity. It is well known that the production of agglutinin, complement fixing antibodies, precipitins, and suchlike does not run parallel with the capacity to resist infection, and it would be interesting to know whether animals which had received injections of the bacterial washings were capable of withstanding a larger lethal dose of the microbe than those animals which had not received such injections or than those which had received one or more of the orthodox vaccines. Another question which arises is how these bacterial washings can be standardized. Accurate dosage is known to be of great importance in all vaccine therapy, and laborious methods are necessary to determine the correct strength of any vaccine. Are the bacterial washings to be standardized by the amount of water used in the process or by the time taken by the operation? But these are technicalities on which no doubt the authors will give more precise information on a later occasion. In the meantime the final and most important question of all—namely, whether these vaccines are of value in the treatment of disease—must be left undecided. The early results are encouraging, but, as the authors say, it is too soon to speak of the main results of the use of antigen.

### ANNUAL MEETING NOTES.

#### THE REPRESENTATIVE MEETING.

In the SUPPLEMENT this week we conclude publication of the full report of the Annual Representative Meeting at Nottingham. The short notes printed below are intended to give, in very general terms, an outline of the course of the discussions during the later part of the meeting.

#### *Monday, July 19th.*

Monday's session, which opened with the introduction of Sir Robert Philip, President-Elect for 1927-28, saw the completion of an important part of the business of the Representative Body. There was relatively little opposition to the Council's proposals about the utilization of municipal maternity hospitals and the fees payable to general practitioners and consultants attending patients in such institutions. This had already been brought forward at Bath, and now became the policy of the Association; but a useful distinction was drawn between fees for occasional attendance and attendance on a salaried basis, and the latter question was referred to the Council for consideration. Later in the session much satisfaction was evident in the reception of Dr. Lyndon's clear statement as to the increased cover afforded by the two English medical defence societies in connexion with the acts of assistants and locumtenents. Of this satisfaction the withdrawal of the motion by the North of England Branch was in itself good proof. The Edinburgh motion arising out of the Harnett case was, however, accepted as a request to the Council, and showed that some uneasiness continues about the position of doctors under the existing lunacy laws. A formula setting out the relation between the Association and the factory medical service raised some difficulties. When these had been overcome the meeting settled down to its most important business for the day—namely, discussion of the Memorandum of Evidence submitted to the Royal Commission on Local Government. During the protracted consideration of this subject the Deputy Chairman, Dr. Hawthorne, took the chair, in order that Dr. Brackenbury, who drew up the Memorandum, might participate with more freedom in a discussion which brought to light a considerable difference of opinion within the ranks of the public health service as

to the effect of the Minister of Health's proposals and of those in the Association's Memorandum. The debate as a whole proved how hard it often is to draw up a policy that allows for future development, and to present it subsequently for ratification at a time when its practical implications are beginning to be grasped. Moreover, issues of the first importance tended to be obscured at times by discussion of the procedure by which the position indicated in the Memorandum had been reached and of the part played by individuals in its development. The report on bills of medico-political interest now before Parliament served to elicit useful statements on the relations between the British Medical Association, the Medical Committee of the House of Commons, and the individual medical members of Parliament, and to define the attitude of the Association towards bills not originated by itself though generally in accordance with its policy. The only point seriously disputed was the recent modification of the Dangerous Drugs Regulations; here the question appeared to be the probable effect of the wording of the Regulations, a matter on which criticism should perhaps await the event. The South Shields motion on notification under the Workmen's Compensation Act dealt with a matter of public importance, and its reference to Council by the Representative Body merely endorsed the action already begun by the Council at the instigation of members in the North of England. On Dr. Morton Mackenzie's motion relating to motor licences an old grievance was discussed, without, however, any practicable solution being found. The Hastings suggestion for a scheme of insurance for members was the occasion of a good description of the scheme established by the dental profession, but secured no support. Medico-political business was brought to an end by a discussion on the use of pituitrin by midwives—a regular feature of the Representative Meeting for some years—and by a reference to the Council of the whole question of schemes for crippled children. The Report of the Insurance Acts Committee provided no controversial matter and was approved without dissent; but the motion on additional benefits put forward by Marylebone led to an interesting discussion, whilst that by Birmingham Central on disciplinary procedure under the Insurance Acts revealed an increasingly strong objection to administrative interference with the practice of medicine. The resolution as passed should strengthen the hands of the Council in a matter which is causing insurance practitioners no small anxiety.

#### *Tuesday, July 20th.*

Tuesday's session opened with a well deserved tribute to the work of the central office staff in the production of the minutes day by day during the meeting—a heavy task undertaken for the first time this year. On the public health report a useful indication of opinion as to the proper basis of remuneration for medical superintendents was given on the Harrogate motion; the number of assistants (the basis originally put forward in 1924) had by general consent many disadvantages. A question of first-class importance which came under review was that of the application of the public health salaries scale in Scotland. The result was acceptance of the report, with a full realization on the one hand of the peculiar difficulties of Scotland in this respect, and on the other of the danger of any local modification of the scale; the ground was then cleared for final decision by the Council. In accepting the Brighton motion on public education in health the Representative Body acknowledged the responsibilities of the Association towards this matter, locally as well as centrally. The discussion on Dr. Langdon-Down's motion to exclude advertisements of appointments which are conditional on membership of a professional organization was

interesting, and revealed a sharp division of opinion. The motion was a logical outcome of that liberal attitude which deprecates any interference with individual freedom in such matters; it was rejected apparently on grounds of expediency rather than of principle, because, as suggested by the Chairman of Council, it would entail the rejection of what was, in effect, a condition advantageous to the individual concerned and to the employing authority. For the rest, the concluding session was spent in the reception of reports rather than in discussion, the chief item of interest being the announcement by Sir Richard Luce of the long-deferred reforms in conditions of medical service in the R.A.M.C., the R.N.M.S., and the R.A.F.M.S. The amount of work contributed by Sir Richard Luce personally in the course of the protracted negotiations on this subject was cordially and gratefully recognized by the Representative Body. No fewer than six reports, including that of the Naval and Military Committee, were dealt with between lunch and the termination of the proceedings, the speed with which business was dispatched during this period being in strong contrast to the general course of events during the first days of meeting. This has happened in some previous years, and, human nature being what it is, will probably happen again. Before proceeding to the usual complimentary resolutions two exceptional matters were dealt with: the sudden illness of Dr. Cowell, to whom an expression of sympathy was conveyed, and the election of Dr. T. W. H. Garstang as a Vice-President of the Association. Dr. Garstang's election was carried with the enthusiasm inspired, not merely by his remarkable record of devotion to the work of the Association, but by the more personal ties he has established with so many of those who have entered on the same service, whether as Representatives or as members of Council, during his twenty-two years as a member of the Representative Body and his three years as its chairman.

#### THE POPULAR LECTURE.

The "popular lecture" was a truly popular feature of the Annual Meeting, for it attracted to the Mechanics' Hall on the Wednesday evening of the Nottingham week an audience which filled it to overflowing. The lecturer was Dr. Leonard Hill, F.R.S., whose subject was ultra-violet radiations. Specimens of lamps used in ultra-violet treatment were placed on the platform and their working demonstrated. The chair was taken by Dr. F. G. Thomson, late President, who took advantage of that meeting of Nottingham citizens to thank them for the welcome they had given to the Association. Dr. Hill began by describing the effect of ultra-violet radiations on monkeys at the Zoological Gardens in London, where the monkey house had been fitted with a series of incandescent quartz lamps in order to let through the radiations during the winter months when sunlight was lacking; in this way the marmoset monkeys had been kept with complete success through what had previously been for these creatures an unfortunate season. In the same way the runs on some poultry farms had been fitted with incandescent lamps to warm the chicks with radiant light, and to give them also a certain proportion of ultra-violet rays, and so diminish mortality. The lecturer then went on to the application to the human subject, and described the work of Rollier at Leysin, of the Royal Orthopaedic Hospital at Stanmore, and, still nearer home, of the "sun-clinic" at Nottingham, where mercury vapour lamps were used for treating the city cripples. He instanced the method used by Dr. Eidinow and himself at the New End Hospital for irradiating the whole body of a child in four sections, followed by a fortnight's rest. The effect of "artificial sunlight" in the treatment of lupus and other conditions

was also illustrated. The amount of ultra-violet radiation in a natural form varied greatly in different parts of the country; for example, Kingsway, in London, received only one-third of the ultra-violet radiation in sun and sky shine which was received at Corton, near Lowestoft. Even under the best conditions, the enormous mass of ultra-violet radiation proceeding from the sun was filtered out very largely, so far as the shorter rays were concerned, by the ozone fifty miles up in the atmosphere. But the city dweller, owing to smoke and to sedentary conditions of life, was deprived in very large measure of this stimulating agent, though certainly it was possible even to produce sunburn through window-glass. The lecturer mentioned the curious experiments whereby a man or an animal might be sensitized to visible rays by the injection of a trace of a fluorescent dye like eosin or haematoporphyrin; also that there were rare cases in which haematoporphyrin, or something like it, existing naturally in the body, caused a similar sensitivity so that the individual dare not venture out into full sunlight for fear of a violent skin reaction. In conclusion, he made a reference to clothing, pointing out that even the thinnest of tropical clothing absorbed the ultra-violet rays. One interesting garment, consisting of a double layer of window-curtain material with a very open mesh—really two garments separated from one another by silken cords, and provided with an opaque cloth for certain parts of the body—had been evolved for country children by a medical colleague of his, though so far he had not ventured to introduce it into the towns. That artificial light baths might be efficacious in dispelling political anxieties was suggested by the public announcement by one of Mr. Ramsay MacDonald's colleagues that the ex-Prime Minister was taking a course of them. Dr. Thomson proposed, and Dr. Brackenbury seconded, a vote of thanks to Dr. Leonard Hill, the former remarking that the investigations into the uses of light were bound to have the most far-reaching results in public health during the next few years, though he trusted that in carrying out the principles Dr. Hill had enunciated both the profession and the public would temper enthusiasm with discretion.

#### THE ADJUSTMENT OF THE CIRCULATION TO THE NEEDS OF THE TISSUES.

THE study of histamine is of particular importance since it has been recognized that the body has the property of forming histamine-like substances under certain conditions. Among such conditions are gross injury to tissues and bacterial infections. It was in relation to at least some types of the bodily state known as "shock" that histamine aroused a widespread interest during the war. More recently it has been shown that histamine-like bodies are perhaps associated with everyday physiological functions such as vaso-dilatation. It was to settle certain anomalous results of the action of histamine in different animals that an investigation reported in a recent issue of the *Journal of Physiology* (vol. lxi, p. 185) was begun at the National Institute for Medical Research, Hampstead, by Dr. J. H. Burn and Dr. H. H. Dale, F.R.S. It was easy to demonstrate the dilator effect of histamine in the perfused limb of most animals except the cat. In this animal the initial vaso-dilator effect was not apparent, but by very careful technique and the use of apparatus that brought conditions in the limb to resemble as nearly as possible those in the intact animal it was shown that the initial dilator effect occurred also in the cat. It became apparent that the excised limb recovered a vascular tonus after a certain definite time, and that if the perfusion of the histamine was begun at the right moment the tonus was inhibited and dilatation was induced in the limb. The

further study of these phenomena has shown that the vascular system reacts differently in its different parts to the same drug. In the dog, for instance, histamine dilates capillaries and the smaller arteries, but contracts the larger arteries. In the cat it dilates the capillaries but contracts the smaller and the larger arteries. In other animals, such as some rodents, the constrictor effect is pushed still further towards the periphery of the vascular system. These observations establish a principle of great importance in clinical medicine as well as in physiology—namely, that the vascular system may react to an effective substance or stimulus, not as a unit, but as a system whose response varies in its different parts. Going still further, an attempt was made to explain the fact that histamine, when injected into the circulation, causes at first a fall of blood pressure which is succeeded by a secondary rise. Adrenaline, when injected into the circulation in small doses, may cause at first a trivial rise of blood pressure, but this is succeeded by a fall of blood pressure. By a series of ingenious experiments evidence was obtained that these reversal effects were due to the liberation in the tissues of a reversing principle. Previous work had given grounds for believing that histamine brought about the liberation of adrenaline. The new observations provide evidence that constrictor substances lead to the production of histamine-like substances in the tissues. This antagonism between constrictor and dilator substances would lead to the establishment of a perfect adjustment of the circulation to the needs of the tissues. An important function of adrenaline is to neutralize the dilator substances produced in the tissues, and so maintain or restore a normal capillary tone. Histamine has proved to be *no mere pharmacological curiosity*, but of great physiological importance, contributing to the balanced control of the capillary tone like the natural secretion of adrenaline.

#### STANDARDIZATION OF ORGANIC SUBSTANCES USED AS DRUGS.

THE need for the establishment of official methods of standardization of drugs which cannot be controlled by ordinary chemical methods is now engaging attention in many countries, and an approach to international action was made at the conference called in 1925 by the Health Committee of the League of Nations, to study the possibility of biological standardization. The movement has now extended to France, where the Minister of Labour, Health, Poor Law Relief, and Insurance recently asked the Academy of Medicine in Paris to undertake the task of creating a laboratory for the control of the anti-syphilitic remedies used in public dispensaries and by medical practitioners. On May 11th the Academy appointed a committee of eleven members to work out the details of the organization of the laboratory, and several additional members were subsequently appointed, among them being Dr. Paul Cazeneuve, who read to the Academy a paper on the physiological control of therapeutic agents, and its official organization. He observed that while inorganic drugs could be controlled by physico-chemical means it was very different with organic compounds and complicated organo-metallic substances. For these physiological control was necessary. Thus it had been shown that samples of organic arsenic derivatives often contained toxic impurities which were difficult to control chemically; for this purpose investigations in a physiological laboratory, by experiments on frogs and guinea-pigs, were necessary, and several drug factories in France, England, and America already made such experiments with a certain number of their products; moreover, the pharmacopoeia of the United States had made the method official in America; and the Pharmaceutical Society of Great Britain

had just established pharmacological laboratories for the control of certain drugs and galenical preparations the value of which could only be determined by biological methods. Such laboratories were necessary in the interests both of the sick and of the pharmaceutical industry. Dr. Cazeneuve suggested that the French laboratory should be established within the faculty of pharmacy in Paris; but though the Academy agreed to the general proposition the objection was made that neither physiology nor medicine was represented in the faculty.

#### MEDICAL MISSIONARY WORK IN AFRICA.

AN International Conference on the Christian Mission in Africa is to be held at Le Zoute, in Belgium, next September (14th to 21st), and in preparation for it a special double number of the *International Review of Missions*<sup>1</sup> has been published. To it Mr. J. H. Oldham one of the two general editors, contributes a statistical article on population and health in different parts of Africa. In many places the population is sparse and appears to be declining in consequence of disease, limitations imposed by the method of life of the natives, and the disturbance resulting from European occupation. Attempts are being made to cope with these depressing circumstances. In Uganda the infant mortality during the first year of life, which was as high as 55 per cent., has now been very materially reduced, as has also the death rate due to sleeping sickness. The native fertility has been seriously affected by helminthic disease, the incidence of which in some districts is very high. Bad sanitary conditions in native villages, the insufficiency of food, and the unsuitability of native diets are other factors in depopulation, while the introduction of Western industrial conditions has also had a tendency to disintegrate native society. An article on health and welfare work, contributed by the Rev. P. H. J. Lerrigo, M.D., gives a detailed description of what is being done by missionary societies to cope with these difficulties. In twenty-seven different geographical areas seventy missionary societies are actively operating; twenty-four of these are British. The medical missionary staff includes 157 medical practitioners, of whom 15 are women, and there are 282 nurses at work. Associated with them are several hundred native assistants, who have received varying degrees of medical training. Most of the medical practitioners are associated with more or less adequate hospitals, of which 136 exist. While some hospitals are relatively large and well equipped, others are of the most elementary type, but still serve to provide more careful medical treatment than is possible in outpatient dispensaries. Over 60,000 in-patients were treated in all the mission hospitals listed in Africa during the last year for which statistics are available. Dispensaries are maintained at 387 places, and are visited at regular intervals by medical practitioners; during 1924 nearly two million attendances were registered. The inadequacy of trained professional help results in a considerable amount of medical work being thrown upon non-medical missionaries, and attempts are being made to train medical assistants, nurses, and health visitors for maternity and child welfare. Although medical education for the African has been almost non-existent, so far as missions are concerned, yet attempts are now being made in various places to provide training, particularly in nursing, midwifery, and elementary medical subjects, in order to supplement the activities of registered medical practitioners. Some special short courses for non-medical missionaries are provided,

<sup>1</sup> *The International Review of Missions*, July, 1926. London: Edinburgh House, Eaton Gate, S.W.1, and H. Milford, Oxford University Press. Prepaid annual subscription 10s. 6d., post free to any part of the world; single copies, 3s. net; special double Africa number, 5s. net.

particularly by the Belgian Government and at Livingstone College in London. It is suggested that a special medical treatise for the use of non-medical missionaries should be prepared by a committee of medical practitioners with a knowledge of the special requirements of the entire African field. It is thought that the awakening of interest in Africa in education at the present time affords a good opportunity for emphasizing the importance of dealing with health problems, and that native teachers might be trained so as to give instruction in personal hygiene and to deal with the problems of African village sanitation. Dr. Lerrigo concludes with an appeal for a definite campaign to control or eradicate such diseases as trypanosomiasis. While the missions are not in a position to make themselves responsible for such a difficult task, their active co-operation in it would furnish a large number of social workers, fully cognizant of the local conditions and able to take a leading part in systematic work. The inauguration of such a scheme would necessarily depend on one or more of the great philanthropic foundations which have been formed in recent years, or involve Government action, since large funds would be needed.

#### ANNUAL REPORT OF THE ROCKEFELLER FOUNDATION FOR 1924.

THE Annual Report of the Rockefeller Foundation<sup>1</sup> for 1923 was noticed in our columns on November 8th, 1924 (p. 869), and the report for the following year is much on the same lines. It opens with a comprehensive review of the world-wide activities of the Foundation by the President (G. E. Vincent), and contains the detailed reports of the Treasurer and the Secretary, of the General Director of the International Health Board (Dr. F. F. Russell), already noted (1926, vol. i, p. 840), of the General Director of the China Medical Board (Dr. Roger S. Greene), of the Director of the Division of Medical Education (Dr. R. M. Pearce), and of the Director of the Division of Medical Studies (Dr. E. E. Embree). The fields of activity of the Foundation compel admiration, for among the nineteen items tabulated by the President are: an allotment of 350,000 dollars towards an international abstract journal of the biological sciences; grants to hasten developments in the medical schools of the Universities of Oxford, Cambridge, Edinburgh, Wales, Montreal, Sao Paulo, Hong-Kong, Siam, and the American University of Beirut; campaigns against yellow fever in South America; malarial control in thirteen States of the Union, and in Haiti, Porto Rico, Nicaragua, Brazil, Italy, Palestine, Queensland, and the Philippines; anti-hookworm work; and directly or indirectly the provision of fellowships for 864 individuals of thirty-three different countries. The guiding principle of the Foundation is concentration for considerable periods upon activities in certain directions, and at present effort is concentrated on public health and medical education. These two fields, however, are very extensive and the ground has been intensively cultivated; as prevention is better than cure, the wise generosity of the Foundation in creating or expanding special graduate schools and institutes of hygiene is obviously a far-seeing policy. Three-fourths of the profession are general practitioners, and some have thought that they may be gradually squeezed out between the specialist and consultant on the one hand and the activities of preventive and social medicine on the other hand. This would be a grave loss; to survive and carry out their most valuable services general practitioners will have to meet the new conditions and become practitioners of preventive medicine or "counsellors of health"; to train such men the curriculum must be

permeated with the preventive idea. Recognizing how indispensable the trained nurse is in public health and medical education, nursing schools at Yale, Rio de Janeiro, Cracow, and Zagreb in Jugo-Slavia have been assisted. The report of the China Medical Board shows that gratifying progress was made in 1924. The Division of Medical Education has not only visited numerous countries to make surveys, but has invited visitors from this country, Hong-Kong, Straits Settlements, and elsewhere to visit America to study the methods of medical education.

#### THE FOUNDLING HOSPITAL SITE.

THE building value of the site now occupied by Covent Garden and its distance from the principal railway stations have led to a suggestion for its removal, and the site of the Foundling Hospital, rendered vacant by the recent removal of that great institution to the country, has been suggested as suitable. It has an area, excluding Brunswick and Mecklenburgh Squares, of about 7½ acres. It is within the southern boundary of St. Pancras, where it adjoins Holborn, and the Holborn Borough Council, a local contemporary states, is opposed to the creation of a large vegetable and fruit market immediately adjoining its area; it fears a congestion of the streets by market carts; and maintains that the noise of the night traffic will interfere with the sleep of the many students lodging in Bloomsbury. It need cause only slight concern to the British Medical Association, for the Foundling site lies at a considerable distance to the south-east of its new House; it is, perhaps, of more consequence to the Royal Free Hospital and the School of Medicine for Women. It is to be hoped that whatever may be the fate of the Foundling Hospital site a certain part of the extensive grounds will be retained as an open space, if not as a recreation ground, for the children of the adjoining areas at present have to go very considerable distances to find green or even asphalt-covered spaces on which to play. Another site for Covent Garden market not far removed from the Foundling Hospital has been suggested. The St. Pancras Borough Council, well supported by local opinion, has taken steps to have the Ossulston Street area condemned; this locality, inhabited largely by coal porters employed in the vicinity, has even in these times of housing shortage been deemed to have reached the last stages of its utility. To some the neighbourhood of St. Pancras Station has been considered an adequate reason for the utilization of the site (about 8 acres, occupied by some 2,700 persons) for a new Covent Garden. Probably most of the population would have to migrate to the newer suburbs coming into being to the north and north-west of London, from which they would have to reach their work by rail; the original proposal was to rehouse them on the site in blocks of nine stories with quickly moving lifts and other amenities. It is, however, doubtful whether the problems of Covent Garden have yet been sufficiently analysed by the appropriate persons. No doubt the trade has outgrown the present market, but the places from which the produce sold there come have not been considered adequately in relation to the best possible site. It is probably true that most of it is brought from the counties west of London, but this should be definitely ascertained, and in fixing the new site consideration should be given to the demand for the lessening of the congestion of traffic generally in London.

THE QUEEN has graciously consented to become patroness of the College of Nursing, Henrietta Street, Cavendish Square.

## POVERTY, NUTRITION, AND GROWTH.

## CHILD LIFE IN SCOTLAND.

THE Medical Research Council has issued a report<sup>1</sup> by Professors Noël Paton and Leonard Findlay of Glasgow, with the co-operation of several workers, on poverty, nutrition, and growth, founded on studies of child life both in the cities and in the rural districts of Scotland. The investigation on which the report is founded was a part of the scheme for the study of the problems of child life undertaken by the Medical Research Council in 1919.

Already several reports bearing upon the ante-natal factors, as manifested in the child at birth, have been published. This report is the first study of the influence of ante- and post-natal factors on the child during infancy (the first year of life), when ante-natal influences may still be operative, and during pre-school years, when home environment may be supposed to be dominant. During the school age, from 5 to 16 years, external conditions are superimposed upon the home conditions, and the child, being in the hands of the educational authorities, has already been fairly extensively studied, and is here only cursorily dealt with.

The investigation was started in 1919; the field work was continued till 1923; and the statistical analyses have occupied two years.

In the introduction to the report it is pointed out that the character of the adult population of any country, its health, vigour, and working capacity, are determined by the development and growth of the children, and that this in turn may be influenced by environment after birth, and also by factors operating while the child is yet unborn, but that many of the factors making for the normal growth and nutrition of the child are still little known. The various hypotheses which have been advanced to explain the small size of the slum child are indicated, and the importance of a more adequate knowledge to guide the operation of child welfare schemes is emphasized.

The children of the slum population of the three great industrial towns of Scotland—Glasgow, Edinburgh, and Dundee—afforded the material upon which the work was done. As a contrast, the condition of the children of agricultural labourers and of rural coal-miners—populations of about the same social class—was also investigated. The extension of the work to these communities was made possible by a substantial grant from the Carnegie United Kingdom Trust.

In Part I a detailed account is given of the slums of the three cities, and this is supplemented in a later part of the report by detailed description of some of the families used for dietary studies (p. 155 et seq., and Appendixes III and IV). Of the town families studied 93 per cent. lived in one- or two-roomed houses, while in Glasgow no less than 43.7 per cent. inhabited one-roomed houses. The social conditions of the rural families studied are described. The contrast between the conditions of these country families and of the slum dwellers is most striking, and is briefly indicated in the conclusions to the reports upon the rural communities.

Since the economic position of the country underwent marked changes during the course of the investigation, between 1919 and 1923, consideration is given to the way in which this affected the circumstances of these families, and a chart shows how closely wages have varied with the cost of living in the class studied.

As regards the racial characters of the population of Scotland, rural and urban, the general conclusion drawn from the results of Tocher's survey is that there are quite definite racial differences, and that the urban populations tend to differ from the rural. In considering the data collected in the present investigation it is therefore necessary to keep in view the possibility that variations in size

which seem to be associated with different environments may be related to racial differences in the populations studied. The measure of growth adopted is height for age, and for nutrition weight for age.

## COMPARISON OF URBAN AND RURAL CHILDREN.

In Part II a comparison of the children of the slums and of rural labourers and miners is made in a series of tables and charts. These show a close correspondence in the growth and nutrition of the children in the three towns. They further show that these slum children are, on an average, lighter and less tall at every age than the children of rural miners and agricultural labourers, the last class being largest at each age. Except for a possible delay below 18 months, the rate of increase, however, is the same in town and in country children. Since no delay in the rate of growth of the slum child is manifest, the conclusion is drawn that the diet must be sufficient at least to supply the material and energy required for normal growth.

The explanation of the differences in the height and weight of the children in town and country is considered and a large amount of evidence adduced, chiefly from previous work, but also from investigations in Dundee described in the report: (1) that this is to some extent due to heredity; (2) that, dealing with large averages, the smaller town dweller begets smaller children than the larger country dweller; and (3) that this difference between town and country is probably being accentuated by the decrease in the emigration from country to town which has recently been pointed out by Brownlee. A typical slum population thus seems to be evolving, and the question is put, May it be that the smaller town race is really an adaptation to environment? Is it not possible that the small machine-tending male, the small, not too prolific female, requiring little food and little exercise, are better suited to urban surroundings than the big brawny man and the large prolific woman whose energies are more appropriately employed in rural surroundings?

The conclusion of this part of the report is:

"Whether environmental conditions are or are not responsible for the lag in growth below 18 months in the slum child, it seems manifest that after that age the inherited growth impulse is sufficiently potent to carry it completely on to the average size of its parents, that the influence of environment is not indicated on the curves of growth of the average of the whole number of children, and that the average diet of the population must be at least sufficient to supply the material and energy required for growth."

## FACTORS INFLUENCING NUTRITION AND GROWTH.

The rest of the report is a study of some of the factors generally supposed to influence the nutrition and growth of children.

After a preliminary consideration of the nature and significance of the evidence presented, the possible relationship of income and the condition of the home with the nutrition and growth of the child is dealt with—in the slum child, in the children of rural miners, and in those of agricultural labourers.

## Income.

Tables are given of the correlation between income and height and weight of the child at different ages, which seem to warrant the conclusion that within the range of income dealt with the variations of height and weight in children under 5 years of age do not appear to be related to the economic condition of the family. Although there is thus an absence of a correlation between income and growth and nutrition, the possible relationship of income to the food value of the typical or average diets of the slum population is considered, and after a statistical analysis of the data available, the following conclusions are reached: (1) that there is a small correlation between the total income and the calories of the diet, but this is due to the fact that in the slum families so high a proportion of the income is spent on food; (2) that between income spent on food and calories purchased there is the expected close correlation; (3) that the energy value of the diet is dependent upon the money spent on food and the energy purchased per penny—that is, upon the marketing, rather than upon the total income.

<sup>1</sup> Medical Research Council Special Report Series No. 101: *Poverty, Nutrition, and Growth. Studies of Child Life in Cities and Rural Districts of Scotland* (assisted by the Carnegie United Kingdom Trust). By D. Noël Paton, M.D., F.R.S., Professor of Physiology, University of Glasgow, and Leonard Findlay, M.D., D.Sc., Professor of Paediatrics, University of Glasgow; with the co-operation of Jean Agnew, Catherine A. S. Blair, M. L. Clark, P. L. MacKinnon, Olive Somerville, and A. M. T. Tully. H.M. Stationery Office, London, Manchester, Cardiff, and Edinburgh, or through any bookseller. Price 10s.

*Condition of the Home.*

The condition of the home, as indicated by the air space per person and the size of the family—both measures of overcrowding—fails to show definite correlations with the weight and height of the children, and does not justify the suggestion that in these homes overcrowding is a dominant factor in influencing the nutrition and growth of the child.

*Diets.*

Part V deals with the determination of the adequacy or inadequacy of the diet of the different groups, urban and rural, to maintain the growth and nutrition of the children. After a preliminary consideration of the relationship of diet and nutrition, it is indicated that the problem to be solved is: how far growth and nutrition are determined by the diet on the one hand, and how far the amount of food consumed is determined by the nutritional requirements of the child on the other hand. A copious diet may help to build up a large child, but the size and activity of the child and its exposure to cold may, in their turn, determine the amount of food consumed. The fact is emphasized that the country child, age for age, is some 11 per cent. heavier than the slum child, and that it leads a more active outdoor life and is exposed to all weathers. It therefore requires a much more liberal diet, and hence, if a difference of even 12 per cent. were discovered between the diets of the two types of family, it would be difficult to decide whether the differences in the weights of the children were the result or the cause of the different consumption of food.

The necessity for accuracy in dietary studies and the enormous labour involved in securing this rendered it impossible to carry out such studies upon all the families investigated. Hence it was essential that those selected should be representative of the whole population under observation. That the families studied actually were so was ensured by the experience of the workers who undertook this part of the investigation, and is indicated by the correspondence of the growth of the children of the selected families with that of the children of the whole group. Each dietary study extended over a week, and the validity of conclusions from studies of this duration is examined and substantiated.

\* This study was made in Edinburgh, the rest in Glasgow; two families series of 15. Efficient of man value was noted. It has been found wife, and three children—der the Atwater standard.  
and, for comparison, this reduction has been made.  
† Five shillings per man per week—that is, total income divided by man value of family.

Details of dietary studies in Glasgow and Dundee and in eighteen families of agricultural labourers are given, while the dietary studies upon seventeen families of miners in Stirlingshire, previously investigated in 1923, are utilized. The average energy intake of these diets may be given as follows:

|   |     |                 |
|---|-----|-----------------|
| Families of city slums (1917-24)          | ... | 2,564 calories. |
| Families of coal-miners (1923)            | ... | 2,917           |
| Families of agricultural labourers (1924) | ... | 3,220 "         |

An attempt was made by statistical methods to find whether there is a correlation between the calorie value of the diet and the weights of the children. With the slum and agricultural labourers' families taken together and with the slum families taken separately there is a small positive and apparently significant correlation between the weight of children and the calorie value of the diet; no such relationship is manifest in the case of the Derbyshire miners' families.

No statistical method can answer the question whether the weight of the child depends upon the diet or the diet upon the size and habits of the child. But that diet is not the main factor in determining the smaller size of the slum child is shown by its unimpaired rate of growth.

It was suggested that the amount of fresh milk consumed might be a factor in determining the differences in weight; but this seems to be negated by the fact that in the miners' families even less milk was used than in the slum families. The conclusions of this section are as follows:

"1. The evidence seems to show that even upon the low intake of something less than 2,600 calories and a supply of only about 0.4 pint of milk per man per day, the city slum child, at least after 18 months of age, grows at the same rate as the country child with its 3,220 calories per man per day. Age for age the country child from 1 to 5 years is some 10 to 11 per cent. heavier than the slum child. It leads a more active life and is more exposed to wind and weather. How far the difference in weight is the result and how far the cause of the more liberal diet is not revealed.

"2. It would seem that the usually accepted 3,000 calories by Lusk's standard as the minimum requirement per man per day for the family diets of our population, more than 80 per cent. of whom are town dwellers, is excessive, and that from 2,500 to 2,700 calories is nearer the correct figure—that is, that the standard might be reduced by 10, or possibly 20, per cent.

"3. The comparatively high correlation of calories in the diet and income (p. 140) and the absence of any correlation between the weights of the children and income (p. 129) seem to indicate that the diet is not the all-important factor in determining growth which it is often supposed to be. On the other hand, some evidence is afforded that below a certain energy intake there is a small correlation between the size of the child and the calorie value of the diet. This may be an example of the law that the effects of changes in any factor may be manifest over a comparatively small range." (P. 115.)

The possible relationship of breast and artificial feeding with growth is next considered, and, as a result of a statistical analysis of the material derived from the child welfare centres in Glasgow, Edinburgh, and Dundee, the conclusion is reached that "in our sample a child who has not been breast-fed at all is, after the usual period of weaning, as good a child as that which has been breast-fed during the whole time."

These environmental factors having been dealt with, the possible influence of parental factors, excluding the influence of heredity, are next taken up.

*PARENTAL FACTORS.*

The intimate relationship of the child to the mother before and after birth is emphasized, and the possible influence of the health of the mother—of either her general health or her health during pregnancy—is considered.

As regards the influence on the child of her health during pregnancy, the conclusion is arrived at that the correlations of both weight and height with maternal health during pregnancy are practically all insignificant, and reveal no distinct relationship between the height and weight of the infant and the health of the mother before its birth, thus confirming Pearson's findings; nor was any relationship between the general health of the mother and the height and weight of the child revealed.

For the study of any influence which the industrial occupation of the mother during pregnancy might have, the Dundee results afforded material, since in that city many of the women are engaged in the jute industry. A statistical analysis of the results led to the conclusion that the correlations of height and weight of the child to the industrial occupation of the mother throughout the series are quite insignificant, and give no evidence that the industrial occupation of the mother is detrimental to the growth and nutrition of the child.

*The Efficiency of the Mother.*

The last maternal characteristic studied was "efficiency." The mothers were classed into those of good and those of

bad or indifferent efficiency, estimated by the cleanliness of the children and the house. Precautions were taken to secure uniform assessment of this quality, and the tables and charts giving the correlations between the height and weight of the child and the efficiency of the mother are held to warrant the conclusion that this is the factor so far investigated most definitely related to the growth and nutrition of the child.

So important did this conclusion appear to be that an attempt was made to determine upon what "efficiency" depends. Are there differences in the innate character of motherliness in woman, as there undoubtedly are in other species of animals, or is "efficiency" related to environmental conditions? If evidence of the latter can be found the possibility of improvement of the condition of the child may be indicated. Is the efficiency of the mother modified by her health? Is it related to the income or to overcrowding? When these correlations are worked out they reveal:

"(1) That there is some slight association of maternal efficiency and income, but evidently within the class studied income is not a dominant factor affecting the efficiency of the mother. (2) That a fairly high relationship exists between maternal efficiency and maternal health. (3) That maternal efficiency seems to be associated to a slightly greater degree with overcrowding, as determined by the air space per person, and with the size of the family than with poverty as determined by income per person. A mother with a large family thus finds it more difficult to care for her home and children than a mother with a smaller family."

The direct correlation of the height and weight of the child had already been shown to be more closely associated with maternal efficiency than with maternal health, income, or overcrowding. But in order further to evaluate the relative importance of these various factors, partial correlations upon the Dundee figures were worked out, with the following results:

"1. Maternal efficiency still shows significant association with weight up to the end of the second year, wholly apart from differences in air space or income.

"2. Air space is of little importance with regard to its influence on nutrition when income per person and maternal efficiency are kept constant.

"3. The correlations of weight and size of family with efficiency of the mother constant are quite insignificant.

"With efficiency of the mother constant, her health seems to have no significant relationship to the weight of the child."

Of the factors studied maternal efficiency is thus the only one which is manifestly correlated with the nutrition in the child, and this seems to hold good, in Dundee at least, till the end of the second year of life. Overcrowding, whether as measured by the size of the family or air space per person, or poverty, as indicated by income per person, does not seem to be a factor related in any significant degree to the nutrition of children. Some evidence is added to show that the nationality of the mother—Irish or Scottish—is not a factor of significance in her efficiency.

An investigation of the mental capacity of efficient and inefficient mothers begun by Dr. Watt was interrupted by his death.

#### *Age of Mother.*

A short statistical study on the relationship of the age of the mother and the position of the child in the family to the height and weight of the child leads to the conclusion that neither of these factors has any great influence on the nutrition of the child, but that, on the average, the order of birth has more close association with weight and height of the child than has the age of the mother.

#### *Habits of Parents.*

One of the factors which it was found impossible to study statistically was the influence of the habits of the parents as regards alcoholism. In Dundee a limited number of reliable observations were secured, and the correlations at least suggest the probability that the children of intemperate parents are, during the first four years of life, somewhat lighter than those of temperate parents.

#### *COUNTRY DISTRICTS.*

The two succeeding parts of the report (Parts VII and VIII) deal with the families of agricultural labourers and rural coal-miners. Each begins with a description of the populations studied and of their surroundings, and these are compared with the conditions in the city slums.

#### *Comparison of Conditions in Families Studied.*

|                           | Income<br>per Person<br>per Week. | Air<br>Space per<br>Person. | Average<br>No. of<br>Persons<br>Living in<br>Home. | Maternal<br>Care<br>Good. | Maternal<br>Health<br>Good. |
|---------------------------|-----------------------------------|-----------------------------|--|---------------------------|-----------------------------|
|                           | Shillings.                        | Cub. ft.                    |  | Per cent.                 | Per cent.                   |
| City slums—               |                                   |                             |  |                           |                             |
| Glasgow ...               | 9.32                              | 404.5                       | 5.3  | 68.3                      | 75.4                        |
| Edinburgh ...             | 8.21                              | 401.4                       | 5.8  | 87.5                      | 85.7                        |
| Dundee ...                | 7.58                              | 400.8                       | 5.5  | 66.8                      | 61.3                        |
| Rural miners ...          | 9.95                              | 531.85                      | 6.2  | 92.8                      | 91.0                        |
| Agricultural<br>labourers | 8.9                               | 750.0                       | 5.5  | 99.6                      | 95.5                        |

A striking difference was the high percentage of efficient and of healthy mothers in rural districts and the lesser overcrowding, as indicated by the greater air space per person. In fact, so small was the proportion of "not healthy" and of "not efficient" mothers that ordinary correlation methods could not be applied. As in the urban studies, the factor most closely correlated with the height and weight of the child was maternal efficiency.

The conclusions as regards the rural coal-miners' community are:

"The results of the study of the relationship of these various environmental and parental factors in the miners' families correspond closely with those obtained in the slum families of the cities. Poverty and overcrowding do not reveal the expected association with the growth and nutrition of the child, while the health of the mother, unless in so far as it modifies her efficiency, is not obviously related. The efficiency of the mother shows the same correlation with growth and nutrition of the child as was found in the slum families.

This investigation seems to indicate that in Scotland the families of the rural coal-miners are reared under environmental conditions altogether superior to those under which the slum child of our great cities grows up. They spend more time in the open air, they are better fed, and, in the vast majority of cases, have the advantage of good maternal care."

As regards the families of agricultural labourers, the conclusions are:

"The general result of the study of the families of agricultural labourers is to confirm the evidence obtained from the investigation of slum families and to indicate that the factor most directly correlated with the growth and nutrition of the child is maternal care—the efficiency of the mother. The study further reveals a pleasing picture of family life, contrasting with the squalor of life in the slums of the great cities. It presents a condition of comfort, good health, vigour, and efficiency."

#### OXFORD OPHTHALMOLOGICAL CONGRESS.

UNDER the mastership of Mr. Philip H. Adams, recently elected in succession to the late Sir Anderson Critchett, Bt., the Oxford Ophthalmological Congress held its sixteenth annual meeting at Oxford on July 14th, 15th, 16th, and 17th. No meeting was held last year owing to the Convention of English-speaking Ophthalmological Societies, but with this exception the Congress has met annually since its inception in 1910. The membership, which in that year was 181, has steadily increased to 380 at the present time. As in past years, the Congress met in the Department of Human Anatomy, through the kindness of Professor Arthur Thomson, and members were again indebted to Keble College for hospitality. The proceedings commenced on July 15th with a short address of welcome by the Master.

#### *Discussion of Sympathetic Ophthalmia.*

A discussion on sympathetic ophthalmia was opened by Mr. Malcolm, who gave a history of the treatment of the condition during the past fifty years. With the dread of sympathetic ophthalmia occurring, even many years after the injury, many eyes had probably been excised which might have proved useful. The general trend of opinion now, however, was against the likelihood of sympathetic trouble appearing after a lapse of years,

and it was to those cases of cyclitis developing within a few months after the exciting cause that he directed attention. Such cases were not all of the nature of sympathetic ophthalmia, and Mr. Hepburn thought that some scientific method should be devised whereby a cyclitis of sympathetic origin could be distinguished from one due to other causes. He suggested that it was not necessary to excise all eyes which manifested keratitis punctata, even though of sympathetic origin, and that many eyes showing that condition after injury or operation should be operated on for the relief of such symptoms. In quoting cases in support of this statement, he emphasized the value of the differential blood count. The finding of a considerable increase in the percentage of the large mononuclear cells with a decrease in the polymorphonuclears was a valuable guide in deciding the line of treatment to be taken.

Mr. S. H. Browning presented the bacteriological side of the subject, dealing chiefly with the question of the differential blood count. Cases were quoted in which a change in the blood count had preceded any other signs of sympathetic ophthalmia, and so determined the line of treatment to be followed. Treatment by arsenical preparations of the "606" type was dealt with and mention made of the anaphylactic theory of the disease.

Dr. G. E. de Schweinitz (Philadelphia), who followed, made special reference to the recent work of Verhoeff, which was presented at the last meeting of the American Ophthalmological Society. Seven cases of sympathetic uveitis were treated by him by frequent subcutaneous or intramuscular injections of diphtheria antitoxin in large doses. In four out of the seven a remarkable improvement in vision was obtained, but the effectiveness of the treatment was most striking in causing a rapid subsidence of the inflammatory condition. Dr. de Schweinitz expressed himself in agreement with Mr. Browning's views.

Dr. Harrison Butler pointed out the value of the slit-lamp in detecting the earliest signs of the disease, and mentioned illustrative cases. Mr. Russ Wood described two cases in which the reaction to tuberculin tests was positive in each. Professor Emile de Grósz of Budapest stated that in the past fifty years 150 cases of sympathetic ophthalmia had been treated at the No. 1 Eye Hospital at Budapest, making 0.28 per cent. of the total patients seen; 10 per cent. of these had followed operations, most of which had been performed elsewhere. In his view repeated operations on injured eyes increased the risk of sympathetic trouble. He was convinced that the inflammation was metastatic in nature.

Lieut.-Colonel H. Herbert referred to the iris-inclusion operation for glaucoma and the supposed risk of sympathetic ophthalmia. Mr. J. Gray Clegg spoke on the occurrence of the trouble after evisceration. Lieut.-Colonel A. E. J. Lister commented on the rarity of the disease in hot dry climates. Mr. A. F. MacCallan, Mr. A. Greene, Dr. Arnold Verrey, Mr. T. C. Summers, Mr. R. J. Coulter, Mr. N. C. Ridley, Mr. A. Zorab, and the Master also took part in the debate, and Mr. Hepburn and Mr. Browning replied.

#### Demonstrations.

The afternoon was given up to demonstrations in the Scientific Museum. Lieut.-Colonel H. Herbert demonstrated an iris-inclusion operation for glaucoma. Dr. G. Young showed statistics relating to ophthalmometry. Lieut.-Colonel A. E. J. Lister presented tables showing the weights of 180 cataractous lenses, with clinical details of the patients' weights, ages, and blood pressures. Dr. Thomson Henderson showed microscopical specimens of the ciliary region in mammalia, and exhibited his apparatus to illustrate the mechanism of accommodation. Mr. Tomlinson demonstrated his light-sense test for the light-adapted eye. Lieut.-Colonel W. V. Coppinger showed (a) a prosthesis of crude Indian manufacture which had cut through the lid of the wearer, and (b) prints of the plans of the new Calcutta Eye Hospital. Dr. Burdon-Cooper demonstrated Pulfrich's phenomenon, and brought forward evidence that the explanation was connected with accommodation rather than with dark-adaptation.

In an adjoining room the most recent advances in ophthalmic apparatus and instruments were exhibited by a number of manufacturing firms.

#### Reports of Cases.

During the morning of July 16th papers were read by Dr. G. Young on the recovery of good vision by an amblyopic eye, and on the cause of the invisibility of the retinal vessels, with an explanation of Purkinje's phenomenon. The former included an account of a man, aged 60, with an amblyopic eye associated with internal strabismus, who had lost the vision of the good eye from embolism; the vision of the amblyopic eye improved in a year from less than 6/60 to 6/6. Dr. Marion Gilchrist presented some interesting medico-legal cases which would have given rise to much discussion had time permitted.

#### Doyne Memorial Lecture.

The Doyne Memorial Lecture was delivered by Dr. Thomson Henderson of Nottingham, who had chosen as his subject "The anatomy and physiology of accommodation in mammalia." Admirably presented in every way, the lecture was followed with the greatest interest. Some original and interesting theories on the physiology of accommodation were put forward, while the anatomy of the ciliary region was shown in a valuable series of slides and drawings from various mammalia, including man. Dr. Henderson was warmly congratulated, and received at the conclusion of his lecture the Doyne Memorial Medal for the year.

#### Intracapsular Extraction of Cataract.

In the afternoon Lieut.-Colonel H. Smith, C.I.E., presented a review of the various methods of performing intracapsular extraction of cataract, and described in detail his own latest method of expression, the outcome of his work during the past winter in India. The paper was discussed by Lieut.-Colonels Lister and Coppinger, Messrs. Zorab, Harrison Butler, Walker, Coulter, and Jaques.

#### Psychology and the Eye.

On the morning of July 17th Dr. T. S. Good, O.B.E., medical superintendent of the Oxford City and County Mental Hospital, read a paper entitled "Psychology and the eye," in which he gave details of cases where the relief of trouble caused by refraction error had had a marked effect in clearing up mental disturbances, and of other cases in which no result was obtained, although eye symptoms were prominent in these, but without abnormality in the eyes themselves. Many interesting points with regard to mental disturbance and sight were raised.

#### Papers.

Dr. Harrison Butler followed with an instructive paper on the signs of inflammation in the eye when examined by the slit-lamp. The proceedings concluded with a paper by Dr. Margaret Dobson on the macular region as seen by red-free light. Some very interesting drawings of the appearance presented by the macula in both normal and diseased conditions were shown, and revealed changes which could not be easily detected by other means.

#### Business Meeting and Dinner.

The annual general meeting was held after the morning session on July 15th, when the council reported that twenty-seven new members had been elected in the past two years, making a total membership of 380; that the attendance at the 1924 meeting was 101; that members and associate members of the Convention of English-speaking Societies last year had been entertained at Oxford by the Congress; and that the financial position was satisfactory. The council regretted to report the loss through death of the following: Sir Anderson Critchett, Bt., K.C.V.O. (Master, 1924-25), Edmund Landolt (Paris), Henri Coppez (Brussels), S. Lewis Ziegler (Philadelphia), member of council from 1911, J. B. Story (Dublin), S. Johnson Taylor (Norwich), member of council 1917-23, Percy Bardsley (Salisbury), C. F. Harford (London), and J. L. Meynell (Manchester).

The annual dinner was held on the evening of July 15th in Keble College; among the guests were Professor Sir Archibald Garrod, K.C.M.G., and Professor J. A. Gunn. The congress was well attended, overseas members being represented by Dr. G. E. de Schweinitz, Professor Emile de Grósz (Budapest), and Dr. Arnold Verrey (Lausanne), among others.

## POST-GRADUATE HOSTEL, LONDON.

THE Post-Graduate Hostel at the Imperial Hotel, Russell Square, London, was formally opened on Monday, July 26th.

Among those present were Dr. Andrew Balfour, Lady Barrett, Mr. A. P. Bertwistle, Dr. H. B. Brackenbury, the Rev. S. D. Bhabha, M.D., Dr. P. J. Chissell (Ceylon), Dr. D. C. Cooper (Adelaide), Dr. Alfred Cox, Dr. C. G. Crowley (Melbourne), Mr. W. McAdam Eccles, Professor Finsterer (Vienna), Dr. Herbert French, Dr. W. Griffith, Dr. G. William Hill, Professor Louise McIlroy, Dr. A. D. Macpherson, Dr. P. Manson-Bahr, Dr. A. A. Martin, Dr. Christine Murrell, Dr. Gilbert E. Orme, Mr. Herbert Paterson, Dr. Porter (U.S.A.), Sir James Purves-Stewart, Dame Mary Scharlieb, Dr. C. F. T. Scott, Dr. W. A. Shea, Dr. Russell Steele, Dr. G. Clark Trotter, Dr. L. R. Yealland, Dr. Zeitlin.

A general meeting was held at 7 p.m., and Mr. W. McADAM ECCLES was voted to the chair. The following, who also form the executive, were appointed as officers:

*President:* Sir D'Arcy Power, K.B.E.

*Honorary Treasurer:* Sir Thomas Horder, Bt.

*Vice-Presidents:* Dr. Alfred Cox, representing the British Medical Association; Sir James Berry, representing the Royal Society of Medicine; Dr. Andrew Balfour; Lady Barrett; and one to be nominated by the Fellowship of Medicine.

*Director:* Mr. A. P. Bertwistle, F.R.C.S.E.

A long list was read of well known men and women attached to the universities and great hospitals of the country who had agreed to become vice-presidents, and it was announced that a large number of letters of approval were continuing to be received from all parts of the country.

It was resolved that the hostel should be open to all fully qualified medical practitioners—that is to say, qualified to practise in the countries to which they belong.

The question of the participation of women in the hostel was discussed, and it was decided that, in addition to the residential facilities, women practitioners should have access to the reading and writing room and to the regular discussions in the smoking room, as well as to all general functions.

After the business meeting some twenty-five dined together under the chairmanship of Mr. McADAM ECCLES, and Mr. A. P. BERTWISTLE proposed the toast of "The Hostel" in an optimistic speech, which was very well received.

At 9.15 p.m. the meeting was resumed, Dr. ALFRED COX being in the chair, and Mr. McADAM ECCLES read a paper on the hostel and its objects prepared by Sir D'Arcy Power, who, owing to illness, was unable to be present. A discussion on the objects of the hostel followed, and many useful suggestions and criticisms were made. Great emphasis was laid upon two points—namely, that the hostel was not intended to compete with any other post-graduate institutions in London, but to be complementary to them; and secondly, that it would stand or fall by its success in bringing the members together socially, and particularly in enabling them to make the acquaintance of eminent physicians and surgeons in London and the provinces, whom at present it was only possible for most post-graduate visitors to know by repute and sometimes by sight. This second object it is proposed to carry out by social meetings, including ladies' nights, and by informal discussions, which will be held at 9 o'clock on one or two nights a week.

It was announced that discussions had been arranged as follows:

*Tuesday, July 27th.*—Operations on the stomach, to be opened by Professor Finsterer of Vienna.

*Friday, July 30th.*—The difference between hyperplasia and inflammation, to be opened by Sir George Lenthal Cheatle.

*Thursday, August 5th.*—Tropical diseases in London, to be opened by Dr. P. Manson-Bahr.

Visitors, both home and overseas, are invited to attend these discussions.

Further information as regards the aims of the hostel may be obtained from Mr. A. P. Bertwistle, F.R.C.S.Ed., 4, Spital Square, Bishopsgate, London, E.

## England and Wales.

## EPSOM COLLEGE.

VISCOUNT GREY OF FALLODON attended the Founder's Day celebrations at Epsom College on July 24th and opened the new chemical block, which has been erected at a cost of £10,000. The building is of brick with stone facings, and will harmonize well with the remainder of the school buildings. The ground floor includes a large lecture theatre, two large classrooms fitted with demonstration desks, a masters' room, preparation room, dark-room, and store. On the first floor there is a main laboratory, which will accommodate thirty boys, a main balance room, an advanced laboratory for sixteen boys, a special balance room, and a combustion room. The front window of the main laboratory is 40 ft. wide, and each room has at least two means of entrance and exit. The building is well ventilated and heated, and when fully equipped will be one of the finest school laboratories in existence. Owing to the present coal shortage the final stages of its construction have been unexpectedly prolonged, but it is already evident that the College, as a medical school, is entering into possession of unsurpassed facilities for the teaching of chemistry. The cost of erection was met principally out of bequests and donations during the last few years, and its provision is part of an extensive scheme to improve the general efficiency of the College. The lower school is at present being enlarged at a cost of over £3,000 to take an additional twenty boarders. Three new classrooms are being constructed, and it is hoped that the work will be completed by the beginning of September.

The headmaster, Mr. A. C. Powell, at the prize distribution in the afternoon, referred to these alterations in the lower school, and explained that the present preparatory school in it was now to be superseded, the minimum age of all new entrants, except foundation scholars, being raised from 8 to 12. Thus, within four years the occupants will become members of the College itself instead of belonging to an almost separate preparatory school. When the proposal to build a new sanatorium and to convert the existing one into a school house has materialized the College will become a public school of 400 boys instead of being, as at present, a school of 260 with a preparatory school of 80 small boys attached to it. The consequent advance in educational efficiency will be associated with administrative and economic gains. The headmaster mentioned also the reorganization of the heating, hot-water, laundry, and steam-cooking systems of the College which is to be effected at a cost of £3,000 during the summer holidays. The east end of the chapel has been panelled in oak; an anonymous donation had been received to redecorate the assembly hall and to provide oak panelling round its walls; and the recent launching of an appeal for money to build a new cricket pavilion had already elicited a most gratifying response. Included in the list of distinctions won by Epsom boys during the year was an open history scholarship at Clare College, Cambridge, an open classical scholarship at Pembroke College, Oxford, and an open Empire scholarship at the Loughborough Engineering College. Mr. Powell concluded with the statement that the popularity of the College might be estimated from the fact that for every boy accepted for entrance next term seven other boys had to be refused or their entry delayed for want of accommodation.

Lord Grey, after distributing the prizes, congratulated the College on its high position in the educational world, and emphasized the physical, moral, and mental value of a public school education. The benefit gained from an interest in outdoor sports persisted through life, and Lord Grey referred particularly to walking and cycling, suggesting that for week-end recreation professional men should adopt personal standards and endeavour to maintain a figure of twenty miles' walking or fifty miles' cycling up to the age of 50 at least. With such physical exercise should be associated some form of mental recreation, the wide scope of natural history rendering it very suitable in this connexion. Such a hobby would confer the greater happiness

which came from activity rather than from the more passive pastimes, and would afford a welcome relief from the daily round of duties.

Dr. Raymond Crawford, who moved a vote of thanks to Lord Grey, spoke of the latter's early days at school and of his courage and high sense of honour in the difficult days preceding the outbreak of the war. During the day a service was held in the chapel, and a cricket match was played between the College and an Old Epsomian team; a choral performance of *Merric England* was given in the evening by the College musical society.

#### UNIVERSITY OF WALES.

##### *Obstetric Research Scholarship founded by Sir Ewen Maclean.*

At a meeting of the Court of Governors of the University of Wales at Swansea, on July 20th, the Pro-Chancellor, Lord Kenyon, said that he had received from Sir Ewen Maclean an offer of £3,000 to endow a post-graduate scholarship in the Welsh National School of Medicine. The offer was made in connexion with the first distribution of the John Maclean medal and prize, which are intended to encourage diligence and proficiency in the undergraduate study of obstetrics and gynaecology. The post-graduate scholarship would be, to quote the words used by Sir Ewen Maclean in his letter making the offer, "for research into the factors which constitute and conditions which vary resistance to disease, especially as regards midwifery. Thanks to the cordial co-operation of Sir William Diamond and the board of management of the Cardiff Royal Infirmary, who supply the premises and bear a considerable proportion of administrative costs of the research laboratory in the maternity department, the scholarship holder would be well furnished with the necessary equipment and ample clinical material." Lord Kenyon expressed the thanks of the Governors and of the University for this splendid gift. Research and post-graduate scholarships were, he said, among the developments most desired by the University. Sir Harry Reichel, Principal of the University College of North Wales, said that the University of Wales was greatly in need of such endowments as this. The absence of post-graduate and research scholarships was detrimental, and tended to cause the ablest students to go to other universities. Sir Ewen Maclean, it will be remembered, is chairman of the British Medical Association's committee on puerperal morbidity, which at the end of last year made an interim report published in the SUPPLEMENT of January 9th, 1926. By his gift to the University of Wales he has shown his interest in the subject in a very practical manner.

#### BRISTOL ROYAL INFIRMARY.

A new pathological laboratory has been installed at the Bristol Royal Infirmary as a gift from the firm and employees of Messrs. Christopher Thomas Bros., Ltd. During the war this firm and its staff inaugurated a fund to give assistance where it might be required, and at the conclusion of peace a balance of about £450 remained. With this money and some additional assistance the new laboratory has been equipped, and was formally opened on July 12th, when a tablet was unveiled, bearing the inscription: "This laboratory stands as a memorial to those employees of Christopher Thomas Bros., Ltd., who made the supreme sacrifice in the Great War, 1914-1918." Colonel P. G. Robinson, president of the Royal Infirmary, gave an account of the extension during the last few years of several other departments, and added that the urgent need for the enlargement of the pathological laboratory could not have been met without the assistance of the firm. Professor Walker Hall, honorary pathologist to the infirmary, described the evolution of the laboratory since 1901, when a small room was opened by Sir Frederick Treves. The outbreak of war had held up a scheme of improvement which was then on the point of being put into operation, and it was a matter of particular interest that the balance of a war fund had now completed a work which had been stopped by the war. The new laboratory is situated in the old building, the necessary space having been obtained by building over part of the existing museum. It includes

an examination room, a bacteriological laboratory with a small private laboratory, and a biochemical laboratory, together with the usual accommodation for media making, histological work, and sterilization. An electrical incubator, a lamp for dark-ground illumination, and a spectroscope are also being provided.

#### CENTRAL MIDWIVES BOARD.

The Central Midwives Board for England and Wales held a penal session on July 15th, which was followed by an ordinary meeting. A resolution received from the Midwives Institute to the effect, "That pupil midwives should not be obliged to take their first five cases in hospital, but that the time should be left to the discretion of the teacher," was considered. It was agreed that the rule should stand, but that the Board should consider on its merits each case brought to its notice. The Board replied to a letter from the Lambeth guardians, by stating that it did not question the efficiency of the lecturers at the Lambeth Hospital, but that the policy of the Board was towards amalgamation of lecture classes wherever possible. Inasmuch, however, as the conditions at St. Giles's Hospital, Camberwell, have recently changed and that many more pupils are now being trained there than when the question originally arose, the Board is willing for a separate class of lectures to be held at St. Giles's Hospital. The Board, however, expressed the desire that lectures, both at St. Giles's Hospital and Lambeth Hospital, should be open to any outside pupils who wished to attend. The Board acceded to the request of the M.O.H. for Rochdale that in the special circumstances, and without prejudice to the principle laid down by it, it is willing to suspend the operation of its decision as to amalgamation of lectures at Rochdale until March 31st, 1928. In reply to a letter from the Kingston Nursing Association the Board wrote that the suggestion of the association was contrary to the principles of the Board that, in matters of septic infection, time, as such, was of no importance; that mere extension of time was no obstacle to infection; and that, if disinfection was efficient, time was no additional safeguard. The Board was therefore unable to fall in with the suggestion that there should be an extension of time of quarantine in the case of midwives who have been in contact with cases of puerperal septicæmia. Drs. Morris Myer Datnow and Sidney Blashill Herd were approved as lecturers. The secretary submitted a statement of the observations made on the resolutions passed at the recent conference between members of the Board and representatives of local supervising authorities; the observations (as amended) were approved and ordered to be conveyed to the local supervising authorities in a letter approved by the chairman. It was agreed to approve, and submit to the Minister of Health for approval, the alterations in the rules which would become necessary as the result of the passing into law of the Midwives and Maternity Homes Bill, 1926, and for other reasons. The next meeting will be held on October 7th.

#### A VISIT TO HARROW SCHOOL.

The Medical Officers of Schools' Association recently paid a visit to Harrow School. During the afternoon the visitors were shown the carpentry and engineering workshops (appropriately fitted with a first-aid cabinet), and an old schoolroom which, although spacious and equipped with excellent chairs and separate desk-tables, the top of which could be made to slope, could with advantage have been better lighted; "4 o'clock Bill" is called outside in winter, wet or fine. A visit was paid to a boarding-house, a large pleasant old-fashioned house where fifty-two boys were boarded and lodged. Some of the boys had single rooms, others slept two or three in a room; in none of the school houses are there dormitories. To this there is a disposition to attribute the rarity of infection, but probably another factor contributes largely—the watchful eyes of the house matrons. In the rooms are the famous Harrow wood-and-canvas beds with their ropes instead of springs and their extra footpiece, all capable of being pushed up into a box cupboard. Before early morning

"prep.," which starts at 7.30 and lasts half an hour, the boys have cocoa and biscuits. The boys have all their meals in their own houses. The sanitary arrangements are beyond reproach. The boys have half-holidays on Tuesdays, Wednesdays, and Saturdays. Soon they will have Sunday school, an arrangement beneficial for any public boarding-school. Attendance at camp and athletics is compulsory. Very little on medical grounds can be said in favour of the large Harrow football, which gets far too heavy, especially in wet weather and is apt to strain the ligaments of the knee; however, boys may run instead of playing football. The cricket and football fields are models, and the open spaces thus provided are incidentally a benefit to the townspeople. The arrangements at "ducker" (the swimming pool) are well supervised; very wisely no boy is allowed to overfatigue himself by bathing more than once a day. The small boys are not overdone by too much keenness in teaching life-saving. While running a mile as fast as possible is too much for boys about the age of 14 or even older, very little fault can be found with running "go-as-you-please." The tuckshop conducted by the school authorities presents certain problems in hygiene—not only that of the maximum quantity to be supplied to each boy, but also of the quality. Obviously, the food should be free from chemical and bacteriological contamination; the chemical preservatives shortly to be legally prohibited should be absent; the effect of these preservatives permitted in limited amounts (notably sulphur dioxide and sulphites) and possibly of certain colouring matters can be more or less easily watched on so closely supervised a population.

#### KIDDERMINSTER HOSPITAL EXTENSION.

The extension of the Kidderminster and District General Hospital to increase the accommodation for children and out-patients has been completed at a total cost of £25,000, and was opened by the Duke of York on July 21st. We have referred previously on several occasions to the efforts of Dr. J. L. Stretton, president of the institution, to raise the necessary money, and on August 22nd, 1925 (p. 359), we gave a short account of the new building. It may be mentioned here that the out-patient department on the ground floor contains a dispensary, dental, ophthalmic, and national health departments, consulting rooms, and a large waiting hall. Each of the two children's wards on the first floor contains forty beds, and the total hospital accommodation is now over 100 beds. Dr. Stretton, welcoming the Duke of York, announced that one of the children's wards had been named the "Princess Elizabeth Ward," and the other the "Stanley Baldwin Ward," in appreciation of the fact that the Prime Minister had started the extension fund with a donation of £5,000 to provide a new children's ward. The total amount of money required had been obtained, and in addition more than £5,000 had been raised for endowment and upkeep. This total sum was equivalent to more than £1 a head of the population.

#### MENTAL DISEASE RESEARCH AT BIRMINGHAM.

The Joint Board of Research for Mental Disease of the University and city of Birmingham, the death of whose honorary director, Sir Frederick Mott, we recently had the sorrow to announce, has now issued the annual report of its laboratory for the year ended March, 1926. During the year the work set forth in previous reports has been continued. Some of this has since been published. A new method for estimating iodine in thyroid substance has been described in the *Biochemical Journal*, and a paper on the iodine content of thyroid gland in the *Journal of Mental Science*. The latter dealt with the correlation of the results of iodine determinations with the microscopical characters of the gland and the physical aspects and mental classification of the patient. Interesting results were demonstrated; septic infection and tuberculosis were shown to be accompanied by great variation in the iodine content of different specimens, indicative of disturbance of thyroid activity. Further detailed research is held to have demonstrated the great importance of the conscious and unconscious contraction and relaxation of muscles in relation to the basal metabolic rate. A normal person sitting in

a comfortable armchair, with his muscles relaxed, and making no effort to concentrate his attention, may show a metabolic rate even below that usually regarded as evidence of hypothyroidism. The question is raised whether the numerous publications of results of the bag methods have sufficiently taken into account these factors. The Research Board considers that before any reliable results can be obtained the question of the relaxation of the muscles must be taken into full consideration, and that it is also important to know whether the patient has had any exercise prior to the experiment, for exercise creates an oxygen debt which takes quite a long time to disappear. These results will shortly be published. An investigation into an outbreak of typhoid fever necessitated the examination of a large number of specimens of faeces and blood. As an outcome of this work, research was commenced into the serological agglutination of mental hospital patients who were being treated with typhoid vaccine in the course of some non-specific protein therapy. Certain peculiar reactions were obtained. The results showed that a large number of patients must have had infection in some time past with organisms of the typhoid-paratyphoid class. Investigations into the permeability of the choroid plexus and brain membranes to certain substances is being carried out by Dr. H. A. Strecker. They suggest the possibility of assistance in the prognosis of cases of general paralysis under treatment based upon the permeability ratio established. They may also assist to an understanding of the secretion of the cerebro-spinal fluid. Other work includes the determination of fat, lipid, and cholesterol ratios of the testes and adrenal gland.

#### RETIREMENT OF DR. F. W. ALEXANDER.

Dr. F. W. Alexander is retiring from the post of medical officer of health for the borough of Poplar on August 15th, after more than forty years' public work in East London. He was appointed resident assistant medical officer to the Mile End guardians infirmary, workhouse, and schools in 1884, district medical officer and public vaccinator for Mile End Old Town in 1887, and went to Poplar in 1893 as medical officer of health in charge of the three parishes of Poplar, Bromley, and Bow. During his period of office there has been an extensive clearance of insanitary areas, and he has been on more than one occasion involved in public controversies in this connexion. The establishment of a cleansing station, the tuberculosis scheme, centres for treatment by light, and other health measures have been his special concern, and he was closely associated with the campaign to make ophthalmia neonatorum a notifiable disease in the county of London, prior to this step being taken throughout the country. One of his recent activities was in connexion with observation wards, which are now in process of construction.

## Scotland.

#### RESIGNATION OF PROFESSOR MATTHEW HAY.

The University Court of Aberdeen University on July 13th accepted with regret the resignation of Professor Matthew Hay from the chair of forensic medicine; and minutely its appreciation of his valued services to the University, extending over the past forty-three years. Principal Sir George Adam Smith reported that a committee appointed to confer with Professor Hay had requested him to postpone his resignation, but he had asked to be permitted to retire from the chair at the end of the current academic year. The members of the court believed that no man of this generation had rendered the University such constant, distinguished, and fruitful service, with such abiding results in the scientific and material expansion of the University in its teaching, finances, buildings, and general administration. Professor Matthew Hay had held the chair of forensic medicine for forty-three years, and during thirty-seven of these he had served as one of the assessors representing the Senatus on the University Court. To the immediate duties of the

chair which he had greatly developed he added instruction in public health. During twenty-four years he had served as Convener of the Finances Committee of the University, and he had taken a leading part in carrying out the University expansion scheme. He had also represented the court on the Carnegie Trust from 1901 to 1920. His fellow members of the court felt very keenly the prospect of parting with a colleague so admired and beloved. Dr. J. Scott Riddell, LL.D., and Professor Ashley W. Mackintosh, as old pupils of Dr. Matthew Hay and fellow members of the University Court, also made appreciative references to his teaching and to his other work on behalf of the University. A copy of the minute of appreciation was directed to be sent to Professor Hay.

#### EDINBURGH GRADUANDS IN MEDICINE.

The Edinburgh and Leith Division of the British Medical Association held a reception on July 22nd for those who had passed the final examination and were to graduate on the following day. Over one hundred graduands were received by the chairman and office-bearers of the Division, and some forty members of the Division and friends were present. The reception was held in the Hall of the University Union. After tea a programme of music was rendered by Miss Armour, Dr. Aitken, Dr. Maxwell, and Dr. E. H. Cameron. During the course of the afternoon a short address was delivered by Sir David Wallace, K.B.E., C.M.G., consulting surgeon to the Royal Infirmary, upon the duties and responsibilities of young practitioners. Speaking of the Rectorial address which Carlyle had delivered to the students of Edinburgh University in 1866, he said that Carlyle's great message to the students of his day had been "Be diligent." In more recent times, Sir William Osler had said that the key to success in the medical profession was work. This attitude of mind was just as necessary at the present day. Carlyle had also inculcated the necessity for a feeling of reverence. The speaker said that at the present day he thought there was a great lack of reverence, in the sense that people overlooked what had been done in the past, and were apt to forget that many modern discoveries had really been known in previous times, as was evident to those who cultivated the habit of reading. He believed it was a good rule for young people to read principally old books and for old people to read new books. There was a great tendency for new ideas to be overdone, especially as regarded new ideas in medicine. To methods of examination and treatment, it should be remembered that there were many ways of doing a thing, and sometimes the way which at the time happened to be attracting public attention was not the best way. It was very difficult, he said, for those of the present generation to realize that modern surgery was very much a growth of the last forty-five years; it might even be said that the greater part of modern surgery belonged to the last twenty-five years. He himself in the eighties of last century had seen the first gall stone that had been intentionally removed from the gall bladder, and this fact alone was an index of the change that had come over abdominal surgery in the intervening years. A modern tendency towards advertising was to be deprecated; practitioners must depend for the increase of their reputation upon the knowledge which accrued to work well done. A copy of the *Handbook for Recently Qualified Medical Practitioners*, of which a second edition was issued in April, 1926, by the British Medical Association, was handed to each graduand, and the chairman made a few remarks upon the value which graduands could derive from its perusal. He also recommended all the graduands without delay to join the British Medical Association, and also for their own protection to become members of some medical defence society. The proceedings terminated with a vote of thanks, proposed by Mr. W. R. Russell, to the chairman and members of the local Division of the British Medical Association.

#### EDINBURGH GRADUATION CEREMONY.

The medical graduation ceremony was held in the McEwan Hall, Edinburgh, on July 23rd. Principal Sir Alfred Ewing capped 16 Doctors of Medicine and 145 Bachelors of Medicine and Surgery. Professor Ashworth, D.Sc.,

F.R.S., acting as promoter, gave an address, in which he said that biology was the very heart and arterial system of medicine, and in recent years the zoologist had come into closer sympathy because of the combined attack which was being made upon diseases that arise from infection with animal organisms or with organisms carried by insects. Investigations in pure zoology had proved to be of the greatest importance in medicine. An illustration of this statement was furnished by the fact that knowledge of phagocytosis was based upon observations made by Metchnikoff, then professor of zoology in Odessa, upon the action of the amoeboid cells in several invertebrates, which, owing to their small size and transparency, could be studied entire and alive under the microscope. Work on zoology in Edinburgh was now done under favourable conditions, because some three years ago a generous gift of £20,000 had been made towards the cost of a new department. This generous patron of science had desired at first that his name should be withheld, and it was not until three days ago that his identity was, with his permission, revealed, and the University had been able to express publicly its gratitude to Dr. Laurence Pullar of Dunbarney by conferring upon him the degree of LL.D. Discussing the bearings of zoology on medicine, Professor Ashworth said that some thirty-five years ago a striking observation had been made upon the egg of a sea-urchin which had undergone its first cleavage into two cells. It had been found that if by shaking the two cells were caused to fall apart each was able to produce an entire individual. This observation had inspired many researches upon the problem of development, and in the last ten years the culture of tissue outside the body had thrown new light on the conditions requisite for the multiplication and differentiation of the cells which built up the body. But this line of investigation, which was yet only at its beginning, was of great promise. No other basal problem was of such importance to medicine as that of growth, and the factors which led to imperfect development, the range of power of regeneration and recovery were all being minutely analysed. The most important element in the treatment of disease was perhaps the fostering of conditions which favoured the natural powers of recovery. It was an integral part of the scientific foundation of preventive medicine that zoology was contributing most directly to human welfare and playing a part in the advance of civilization. In this great endeavour one of the primary factors was the sound education of the student and graduate in his appreciation of the difficulties and needs of mankind.

#### EARLY MENTAL TREATMENT.

The chairman and managers of the Royal Mental Hospital at Morningside, Edinburgh, on July 22nd inaugurated a nursing home for mental cases, which has recently been acquired and fitted up at the mansion house of Vogrie, some ten miles south of Edinburgh. It has a well wooded park and the surrounding policies cover some 300 acres of park land, pleasantly diversified by heavy timber and situated in the beautiful valley of the Tyne. Provision has been made for some thirty to forty inmates, and in the basement extensive kitchen and storeroom premises have been fitted up. Mr. T. M. Gardiner, chairman of the board of managers of the Royal Mental Hospital at Morningside, presided at a luncheon at which were present Professor G. M. Robertson, physician superintendent and President of the Royal College of Physicians, Professor Lorrain Smith, Dean of the Faculty of Medicine of Edinburgh University, Dr. Hamilton C. Marr, and numerous other members of the Board of Control for Scotland and of the medical profession in Edinburgh and surrounding district. The chairman traced the history of Morningside Hospital. In 1773 Robert Ferguson, a poetic genius whose work had been much admired by Robert Burns, was struck down by an attack of furious insanity. His medical adviser at once suggested that he must be placed under restraint, and in those days the only available refuge for such cases was the City Pauper Bedlam; to this miserable institution Ferguson was conveyed. The poet gradually lapsed into a condition of profound melancholy and died some ten months later. His illness and

Duncan, with the determination that some better provision should be made for those unfortunates who lost their reason. Duncan was at that time a young man of 30, and when he visited his patient his mind was profoundly impressed at finding him lying upon straw on the stone floor of a cell whose only window was devoid of glass. In 1790 Duncan was elected President of the Royal College of Physicians, and immediately brought before the council of his college a plan for the better treatment of the insane. Some three years later (in 1793) a campaign was launched to raise the necessary funds, but owing to the Napoleonic war and the disturbed state of the country real headway was not made till 1806, when, with the assistance of the Lord Provost of Edinburgh, the Lord Advocate, and various members of Parliament and other influential persons, a grant of £2,000 was obtained from the Crown out of estates which had been sequestered after the rebellion of 1745. With this sum a site was purchased in Morningside, and on June 8th, 1809, the foundation stone of the Royal Asylum at Morningside was laid, the building being completed and the first patient admitted on July 19th, 1813. Since that time great advances in the treatment of mental patients had been made, and the institution had been kept in the forefront of improvement. Some years ago the managers began to realize that a serious gap existed: for persons showing signs of mental breakdown there was no intermediate stage between going into an asylum or being cared for at home, the latter alternative being in most cases out of the question. It was the fact that a stigma had attached to patients in an asylum, with the result that in many cases proper treatment was not sought and obtained until the disease had got a firm hold. Better knowledge was now evidenced by the fact that of new entrants at the Royal Mental Hospital over 60 per cent. were now voluntary patients—that was to say, they had not been certified but were there of their own free will. This had induced the managers in 1917 to purchase a house and equip it as a nursing home in which early or incipient cases might be treated, thus removing the necessity for such patients to enter an asylum. This experiment had met with such immediate success that they had opened other nursing homes, all of which had prospered. The one weak spot was that, of necessity, these homes were only available for persons fairly well off. For poor patients the problem was not easy to solve, but the managers had before them plans which they believed would do for poor patients what the existing nursing homes had done for the more well-to-do.

Dr. Hamilton Marr, one of the Commissioners on the Board of Control for Scotland, spoke of an advance in the treatment of the insane with which Professor Robertson had been associated. That was the substitution of women nurses for men to look after people who were sick in mind. A deputation of ex-service men had, he said, visited the Board of Control to remonstrate about the introduction of nurses into asylums, as displacing male employees. Each member of the deputation was asked whether as a soldier in hospital he had preferred to be tended by an orderly or by a nurse, and the answer in each case had been, "I preferred a nurse." The speaker's reply to the deputation had been: If they preferred a nurse when they were sick in body, why should they seek to deny the same privilege to those who were sick in mind? The deputation had had nothing further to say. The Board of Control had arranged with the Board of Health to have observation wards, in which persons suffering from mental disease could be treated exactly on the same lines as patients suffering from physical disorders, under the same excellent conditions that obtained in general hospitals. The Board of Control had very great sympathy with the establishment of nursing homes such as that now inaugurated at Vogrie. Professor Lorrain Smith, in moving a vote of thanks to the chairman and board of managers, referred in appreciative terms to Professor Andrew Duncan, whose great work for the Edinburgh medical school had, he said, not been sufficiently appreciated. At the present day, under the superintendence of Professor Robertson, there was a greater development in the care of the type of patient who was to be accommodated at Vogrie than anywhere else in the British Empire.

#### HEALTH OF EDINBURGH.

The annual report by Dr. William Robertson, M.O.H. Edinburgh, for the year 1925 contains many interesting facts about the health of the city. Statistics show that the birth rate in the city for 1925 was the lowest for the last five years, during which there had been a progressive decline. The population of Edinburgh in 1925 is given as 421,968, an increase of 2,677 over 1924. The density of population is 13 persons per acre. The number of inhabited houses was 102,431, being 806 more than in 1924. The cancer death rate was 1.6 and the phthisis death rate 1.0, in both instances the same as in 1924. The epidemic diseases death rate was 1.1, an increase of 0.1 over that for 1924.

**Scarlet Fever.**—The chief epidemic feature of the year had been the occurrence of a considerable outbreak of scarlet fever, of which 2,351 cases had been notified (590 more than in the previous year). The type of disease had, however, been much milder than previously, and the mortality rate had been low. The same factor had, however, rendered the task of detection difficult, and thus the spread of the disease in schools had been more difficult to check. Attention is drawn to the increasing production of cheap forms of sweets, and the suggestion is made that while these may be harmless in themselves their circulation from child to child may be a source of the spread of infection. So far as the Public Health Department knew, there had not been any case of milk-borne infection. Of the cases of scarlet fever, 63 per cent. had occurred in dwellings of two or three rooms, and the suggestion is made that lack of adequate ventilation had much to do with the infection of susceptible members of the families housed under these conditions. It had become necessary during September, when notifications were reaching the department in great numbers, to issue a circular letter to medical practitioners, inviting them to encourage the treatment of cases at home. Suggestions had been made regarding the home treatment of cases by painting the throat with carbolyzed glycerin and anointing the surface of the body with eucalyptus oil in cases where domiciliary treatment was carried out, and it is believed that these measures were of value. The cases removed to hospital numbered 1,944, or 82 per cent. of the total for the year 1925. A sum of nearly £3,000 had been saved through the domiciliary treatment of a proportion of the cases. There was never any evidence that home-treated cases led to a spread of infection to neighbouring houses, and an effort was always made to isolate susceptible persons by transferring the younger members of the households to the houses of relatives. Second cases had occurred among only 8 out of the 407 patients treated at home (1.9 per cent.). On the other hand, the return rate for cases treated in hospital was 3.2 per cent. Dr. Robertson mentions his experience in Leith with 200 consecutive cases of scarlet fever treated in their own homes without any other member of the households becoming infected. Patients with scarlet fever sent to hospital and running a normal course without complications were not kept in isolation for six weeks. It had been found in Leith that the duration of residence in hospital could in many instances be reduced to twenty-eight or thirty-five days, and this procedure had been adopted in Edinburgh. A case is mentioned in which an outbreak of scarlet fever of explosive character had occurred during this year in a large boarding-school for boys. A member of the staff was found to be harbouring the *Streptococcus haemolyticus*, and after this person had been isolated the epidemic died out in the school.

**Diphtheria.**—In furtherance of a scheme begun in 1924, when over 3,000 school children had been immunized against diphtheria, the Public Health Department had carried out the same scheme among children of pre-school age. An appreciable number of children of the pre-school age presented themselves at the centres, but it is too early to give the results of this work.

**Artificial Sunlight.**—Apparatus for artificial sunlight has been established at the City Hospital for the treatment of measles and whooping-cough, and also in the annexes devoted to surgical tuberculosis. Mercury vapour lamps have been installed also at the child welfare departments, and at the Victoria Park Convalescent Home and other

centres. Good results have been obtained both from the use of open arc and mercury vapour lamps. Ozonizing plant has also been installed in apartments used for the treatment of surgical tuberculosis, and this has been found valuable in securing freshness of the atmosphere where patients are stripped for artificial sunlight treatment during the colder months when windows cannot be wide open.

**Clean Milk.**—Reference is made to the establishment of a herd of tubercle-free cows by the local authority at Colinton Mains Farm, and it is stated that the supply of high-grade milk has grown to large proportions in the city. The opinion is expressed that there is at present too wide a gap between high-grade milk and ordinary commercial milk. While much is to be said for the producer who cannot afford to collect a herd of tuberculin-tested cows free from tuberculosis, there is no excuse for any dairyman who refuses to produce clean milk. Constant attention to cleanliness with concentration on keeping everything about the cows clean are the prime factors. Much good in this direction has been done by the milk competitions introduced two years ago by the Edinburgh municipality.

**Tuberculosis.**—A wave of gradual decline in tuberculosis has manifested itself during the past fifty years, and much of this is ascribed to the educational work that has been done. Regret is expressed that millions of pounds have been spent on the erection of types of houses that the slum dwellers could not afford to occupy. It is hoped that the elimination of the breeding places of tuberculosis will be systematically carried out when the new housing schemes begin to give proof of their preventive value.

#### EDINBURGH UNIVERSITY ALUMNI ASSOCIATION.

Under the auspices of the Edinburgh University Alumni Association a dance was held in the M'Ewan Hall on July 20th, at which some eight hundred were present. Sir Harold Stiles said that he had taught in the university for forty years, and its welfare was of great moment to him; the Alumni Association now included some 1,200 members, which was 1 in 10 of the alumni of the university. Sir Arthur Steel-Maitland, the Minister of Labour, also made a plea on behalf of the association. He said that as a graduate of Oxford University he felt that one of the greatest advantages he got at that university was from the corporate life of the college. It was a wonderful advantage in after life for any man or woman to feel that the old university associations and friendships were being kept alive, and that was the reason for asking them to give their help by joining this Alumni Association.

#### HOSPITAL PAGEANTS.

A pageant was held in Edinburgh on July 3rd in aid of the funds of the Royal Infirmary. This has been for some time an annual event, but on the present occasion it had to be deferred for two months on account of the general strike. The fact that the university students were unable to co-operate owing to the change of date deprived the procession of what is usually one of its most striking features. There was, however, a great turn-out of decorated cars, tableaux, and figures in costume, and the carnival, which is really what this effort has now become, must have stretched along the streets for over a mile. As a result of collections made in the street and subscriptions taken at the various works during the day, a sum of about £3,000 was realized for the benefit of the Infirmary.

These galas or carnivals, organized chiefly by students, have now become an annual institution in connexion with the large teaching hospitals of Scotland. Some two months ago Aberdeen students raised a sum of between £4,000 and £5,000 on behalf of the funds of the Aberdeen Royal Infirmary and other local hospitals. Of this sum over £1,000 was collected in the streets of Aberdeen, and in addition there was a house-to-house collection, a fancy dress ball, a carnival in the Duthie Park, and the sale of a special number of the university magazine, *Alma Mater*. Various concerts were at the same time organized throughout towns and villages of the neighbouring counties.

## Ireland.

#### CENSUS OF NORTHERN IRELAND, 1926.

THE Registrar-General's preliminary report on the census recently taken in Northern Ireland contains statistical notes and a series of tables showing the population by sexes; the proportion of females to males; the distribution of persons as between urban and rural areas; the density of population (per acre and per room); the number of habitable buildings; the number, size, and constitution of families occupying one-room tenements in Belfast and Londonderry; and the number of persons aged 70 years and upwards. Statistics are given for each county, county borough, and ward of county borough, urban district, rural district, town created under the Towns Improvement (Ireland) Act, and town of undefined boundary containing 1,000 or more persons, or aggregation of these; and figures relating to previous censuses are included in the tables for purposes of comparison. The estimates of population based on previous census figures corrected for the excess of births over deaths, net migration, and the movements of military, together with the more important vital statistics covering a series of years, are to be found in the *Ulster Year Book*, the second edition of which is now on sale. Both volumes may be obtained from H.M. Stationery Office, 15, Donegall Square West, Belfast, or through any bookseller, and the price of each is 1s., post free 1s. 2d.

#### NATIONAL VETERINARY MEDICAL ASSOCIATION.

The annual congress of the National Veterinary Medical Association was held in Dublin from July 27th to 30th, under the presidency of Professor J. B. Buxton, the director of the recently established Institute of Comparative Pathology at Cambridge.

#### Milk.

Mr. Dolan, the chief veterinary inspector to the corporation of Dublin, read a paper on the production and handling of milk. Milk at its source, he said, must be free from pathogenic organisms, including tubercle bacilli; it should be produced only from clinically healthy cows, be handled under good, clean conditions, and pasteurized only when required. The contamination of milk before it reached the consumer might result from the shed, the cow, or the milker. Sheds must not only be clean but, to preserve the health of the animals, must have a sufficient floor space suitably arranged for cleansing, and be efficiently ventilated and lighted. It was better to fix a minimum height and floor space rather than a minimum cubic capacity, and to draw a distinction between closed and open sheds when considering capacity. Contamination of milk from the cows themselves could be reduced to a minimum by grooming and using a covered pail. Mastitis was more frequently due to cocci than to tubercle bacilli. The milker must be clean and use overalls. To strain milk was a confession of failure; it removed only the grosser particles, and if milk required straining it meant that unnecessary contamination had previously occurred. Even to the small producer cleanliness was not expensive. The ideal condition was to produce milk from healthy cows, under good hygienic conditions, and then to bottle it to prevent subsequent contamination. Milk removed in sterile churns and bottled subsequently under good conditions was also clean; but when sold from vessels or unsuitably bottled it was dangerous. He considered that all milk sold should come under some grading, and suggested that milk not coming within any of the Ministry of Health gradings as at present defined should be called "Grade B," and that such designations as good, pure, new, or guaranteed fresh, should be illegal. He suggested also that the present "certified" and "Grade A (T.T.)" should be combined and sold under the title of "certified." Sufficient control was not exercised over milk that found its way into bakeries and similar places and milk which was made into butter.

#### Diphtheria in Poultry and Man.

Mr. J. P. Rice (Animal Diseases Division, Ministry of Agriculture, Northern Ireland), in reviewing the diseases of poultry which occur in Britain, said that though true avian diphtheria was distinct from human diphtheria the *Bacillus diphtheriae* of man was pathogenic for birds, and produced diphtherial lesions in them. The possibility that occasionally birds affected with the human bacillus might spread infection to man could not be excluded. Avian diphtheria was caused by a filterable virus, and was the cause of avian chicken-pox.

*Swine Erysipelas in Man.*

Mr. J. F. Craig (Principal of the Dublin Veterinary College) read a paper on swine erysipelas, and drew attention to the fact that the disease was communicable to man through wounds or abrasions of the skin, usually from the handling of carcasses or accidental inoculation of cultures. The lesion was local, and most commonly developed about the hand or arm. It consisted of a painful reddening and some swelling, which formed around the seat of inoculation, and might spread over a considerable area, be attended by swelling of the neighbouring lymphatic glands, and, very rarely, swelling of the neighbouring joints. The affection might persist for some weeks, but readily responded to antiseptic treatment. The disease was very common in pigs in this country, and was due to a bacillus very similar to that causing mouse septicaemia.

*Pylorhoea in Dog and Cat.*

In a paper on pylorhoea in the dog and cat Mr. Henry Gray (London) said that it had been known for over a hundred years. It attacked any breed, but more especially lap and house dogs fed on soft food. It was never seen in animals which used their teeth regularly for the reduction of their food and gradually wore them down in the process; its incidence and severity increased with the age of the animals. There seemed to be no hereditary predisposition to the disease, and where it occurred in succeeding generations it was due to the same continued pernicious habit in feeding. The causes of pylorhoea in dogs and cats were dirty teeth and lack of pressure on the alveolar walls. It could be entirely prevented by suitable feeding, and a healthy dog which, as soon as it was weaned, was given suitable food which had to be reduced with its teeth, might be maintained in perfect health if fed only once in twenty-four hours. Pylorhoea had many complications owing to the absorption of the toxins produced in the alveolus. If the animal became depressed by a chill or some other cause these toxins caused gastric, enteritic, neuritic, or meningeal attacks, which coincided with adverse changes in the weather. Arthritis was occasionally encountered, while chronic interstitial nephritis and chronic bronchitis might both be due to the same cause. Although there was no evidence that the disease was transmitted from dog, cat, or man to each other, there was danger of people becoming inoculated with the putrid material from the affected animal's mouth. Many people had developed serious wound infections from this source. This side of hygiene did not seem to have attracted the attention of public health officers, or probably even the notice of the family physician. Owners in general were absolutely ignorant as to how to feed a dog or cat and thereby maintain its health—a fact which was not entirely their own fault. Mr. Gray described at some length the natural methods of feeding these animals, and showed that both dogs and cats from 3 months and upwards could reduce and digest bones and other rough material. Pylorhoea, he declared, was a preventable disease, which was caused only by feeding on food which did not require to be crunched before being swallowed, and this, he said, was true for man as well as animals.

In addition to the papers here mentioned, addresses on sterility and on liver fluke disease in ruminants were delivered.

**New Zealand.**

[FROM OUR SPECIAL CORRESPONDENT.]

**THE HOSPITAL SYSTEM.**

THE hospital system in New Zealand is under the control of the Minister of Public Health and the Health Department and of boards of trustees elected on a municipal or borough franchise. The majority of the smaller hospitals have no honorary staffs, and the cost of hospitals is borne mainly by the Government Consolidated Fund and local rates, and only to a minor extent by payments from patients and voluntary contributions. According to law the public hospitals are open to all classes of the community, rich and poor alike, but in practice well-to-do patients seldom take advantage of their legal right to enter hospitals as patients. Middle-class patients are reluctant to enter general wards, and are treated at home or in private hospitals, where the facilities for treatment are not comparable with those provided in the special departments of a large and fully equipped general hospital.

The New Zealand Branch of the British Medical Association recently invited Dr. M. T. MacEachern, in charge of the hospital activities of the American College of Surgeons and President of the American Hospitals Association, to

visit New Zealand and report on the hospital system. By arrangement this report was presented to the New Zealand Government. Dr. MacEachern made a careful survey of a large number of hospitals in the dominion and created a very widespread public interest in hospital work. Prior to his visit the public took little or no interest in hospital administration and reform, and left these matters too much in the hands of the Health Department, the trustees, and the medical superintendents. The members of the honorary medical staff have had little voice in hospital affairs, and if at all vocal are threatened with supersession by the creation of a full-time stipendiary medical staff. Dr. MacEachern, in his report, has pointed out that hospital practice and private practice cannot be divorced without serious detriment to both hospital and private patients. He has also emphasized the fact that voluntary effort should not be discouraged by close reliance on rates and taxes, and that taxpayers and ratepayers have fully as much right to hospital facilities as the class who pay little or nothing to the general revenue. In short, he advocates the "community" hospital, in which the poor are free, an intermediate class pays modified charges, and a paying class contributes the full cost of maintenance and medical services, all paying patients having special wards apart from the general wards for necessitous patients, and the right of choice of their own medical adviser. If the community hospital system is established the result will be that gradually the smaller and least efficient private nursing homes will be forced out of business. The medical profession in New Zealand is in favour of free service for the poor, but when public hospitals are open for all classes of the community there appears to be no reason why the profession should not be fully paid for its services by such as are able to pay. The Labour Party in New Zealand holds that there should be no individual payment for hospital service, and that it is the duty of the State, by rates and taxes, to provide "free" treatment in all public hospitals for rich and poor alike, without, as it is termed, class distinction.

**AUSTRALASIAN MEDICAL CONGRESS.**

The Australasian Medical Congress meets in Dunedin in February, 1927, and much preliminary work has been done to ensure its success. The congress is to have twelve sections, and the meetings will be held in the new and commodious buildings of the Medical School. Visitors from the British Isles will be very welcome and will have opportunities for recreation, engaging in trout fishing and other sport, or in viewing the varied attractions of New Zealand scenery. [Information about steamship routes and fares will be found in the SUPPLEMENT this week at page 97].

**Correspondence.****MINER'S NYSTAGMUS.**

SIR,—As ophthalmic referee to two northern districts (1 and 2) I have had good opportunities of studying the subject in this neighbourhood, and on May 5th, 1923, you kindly published my criticism of the first report of the Miners' Nystagmus Committee.

Owing to the courtesy of the owners I obtained details of some thirty-two pits in Northumberland and Durham, and the number of new cases of nystagmus that received compensation during the year 1922. Of 36,232 underground workers, 11,383 were hewers and 24,849 were non-hewers; 103 of the hewers and 59 of the non-hewers acquired nystagmus and received compensation during the year 1922. All these men were subject to the same deficiency of light; if this were the cause of the disease the percentage of the nystagmus cases among the hewers would be equal or nearly equal to that among the non-hewers.

$$\text{But } \frac{103}{11,383} : \frac{59}{24,849} = 0.904858 \% : 0.237434 \%$$

This definitely confutes the first unanimous conclusion of the committee that "the essential factor in the production of miners' nystagmus is deficient illumination."

Electric lamps were advocated in the first report of the committee, and I was not able, until 1924, to find any pits in which electric lamps were used solely. The only two pits which had used them solely gave full corroboration to the views I expressed in 1923.

(1) *The Plenneller Pit*.—In 1922 nearly 4.3 per cent. of the hewers and 1.3 per cent. of the non-hewers acquired the disease—that is, the percentage of hewers affected was 4.7 times greater, and that of the non-hewers was 5.5 times greater where electric lamps only were used.

(2) *The South Moor Colliery*.—Here twenty-five years ago electric lamps were used solely, and the percentage of their nystagmus cases was notoriously high; but on abolishing their electric lamps and installing *oil safety lamps* they had no cases of nystagmus amongst their non-hewers, and hardly any among their hewers.

The above I quote from my letter to this *JOURNAL* of March 22nd, 1924 (p. 550), in which I give my suggestion for checking the disease. Further comment is unnecessary.

I am in entire agreement with Dr. Freeland Fergus as to the relative insignificance of deficiency of light as a factor in the causation of the disease; indeed, as no one had replied to my letter, I had hoped that that view had been given up.—I am, etc.,

Newcastle-on-Tyne, July 18th.

A. S. PERCIVAL.

### RHEUMATIC HEART DISEASE IN CHILDREN.

SIR,—It can hardly be doubted that the key to the etiology of rheumatic infection lies concealed in its class incidence, and that the narrowing of the class typically affected to the moderately poor, the skilled artisans, is a valuable step towards finding it. The logical next step would seem to be a study of the distinguishing characters of this class, and I would suggest that this study should not be confined to environment, but should include, as being at least of equal importance, the mental outlook of the class on matters of hygiene and the habits of life engendered thereby.

Environment, in almost all its aspects, has been very carefully considered by Dr. Miller in his report (*SUPPLEMENT*, July 3rd, 1926) but the more intrinsic class characters seem to have received less attention.

It will be generally admitted that a profound belief in the evil effects of cold air near the body is a first article of faith with almost the whole of the poorer classes, that they have an almost equal dread of "overheating" by strenuous exercise, and (rather less characteristic) a firm belief that children, especially, need a very generous diet. The familiar plump or well covered child of whom it is said "she eats nothing" or "I have to force the food on her" is witness to this last. As a result the children of the poorer classes wear many layers of close-fitting clothes, the rooms in which they live are kept very warm, strenuous exercise, at least for girls, is disapproved, and they are encouraged to eat freely of a diet largely farinaceous. All this applies more to girls than to boys and more to the moderately poor than to the destitute. The very poor, even if they aim at the same standards of warmth and diet, cannot attain them. Their children are scantily clad, obviously underfed, and spend much time loose in the streets or, if they are lucky, on the swings and giant-strides of public playgrounds.

The children affected by these class habits thus correspond both in sex and social standing with the typical rheumatic subject.

If damp, taken alone, were a chief factor, one would expect the class incidence to vary directly with the degree of poverty; but the combination of an atmosphere both damp and warm, with many layers of clothing, ample diet, and little countervailing exercise, should be capable of a powerful effect on metabolism and is fairly well recognized as a cause of chronic or recurrent catarrhs. I suggest that this combination may be the essential factor in preparing the rheumatic soil, and deserves at least as much attention as damp in buildings or clothes. That it is the factor actually at work would be difficult to prove, though the temperature and humidity of rooms, the caloric value of diet, and the number of layers of clothing are all measurable, and the class incidence of the combination could be ascertained.

The large-scale experiment of the war, when a whole population of young men lived in "damp basements" or their equivalent, with, as Dr. Miller notes, very little acute rheumatism, should not be forgotten; and it would be instructive to know whether the class incidence of rheumatism was the same sixty or eighty years ago when the hygienic ideas of the rich were more nearly those of to-day's poor.

Meanwhile intensified propaganda in favour of fewer and looser clothes, cooler rooms, and more exercise could do nothing but good.—I am, etc.,

Hampstead, July 16th.

LINDSEY W. BATTEN.

### THE PROPHYLACTIC VALUE OF SCARLET FEVER ANTITOXIN.

SIR,—Dr. Harries replies (July 17th, p. 134) to my criticism of the paper published in the *JOURNAL* of May 22nd by himself and two others, but he does not excuse himself for basing a conclusion upon the unreliable supposition that further cases must have occurred amongst fourteen contacts with a scarlet fever case but for the production of "a temporary passive immunity" by inoculation with scarlet fever antitoxin. He has to assume that the positive Dick test is not only "a reliable index of susceptibility, or otherwise, to the toxin produced by the *Streptococcus scarlatinae*," which in this case amounted to practically all the contacts, but that it is also an index to the number of secondary cases of actual scarlet fever that may be expected to arise among the contacts with a first actual case. According to the reading of his Dick test, 100 per cent. of the fourteen contacts would have got scarlet fever, an estimate out of proportion to the numbers indicated by former actual experience of scarlet fever, as registered through many years, for instance, in the infectious diseases registers of the Health Department of the Birmingham Corporation, to which I think Dr. Harries might have applied himself with advantage as a preliminary before starting on his experiments with the Dick test and antitoxin injections. In contemplation of the actualities there recorded, he might have considered whether they are likely to represent the indications of the Dick test, supposing that had been widely applied in the communities of children amongst which the Birmingham actual scarlet fever cases arose. If not, any difference must be placed to the discredit of the Dick test, not, perhaps, as an actually proved thing, but as a very sound likelihood or expectation.

Dr. Harries seeks to buttress his position by reference to a paper published in the *JOURNAL* of January 30th, 1926 (p. 214), by Dr. D. C. Kirkhope, who forms and publishes a conclusion every bit as irrational as that of Dr. Harries, and for a similar reason. As to the first part of Dr. Kirkhope's paper, it is a pity that such a considerable artificial production of symptomatic conditions should have resulted in so little certainty of positive benefit, or increase of our knowledge of the subject. The part of Dr. Kirkhope's paper quoted by Dr. Harries, which concerns scarlet fever in a school, is particularly wanting in detail, and indefinite in expression. The author first concentrated the serum (? by evaporation with heat). He then administered this concentrated serum to "140 contacts with 41 patients," giving them injections of 2½ to 5 c.cm. There were reactions, and no reactions, from which nothing was deduced. Then, in addition, he inoculated 131 school children derived from school classes "where scarlet fever cases were recurring with unhappy frequency. . . . The teachers were instructed to space out the inoculated children alternately with the others. From the time of the inoculation no further cases occurred for a fortnight, and all the inoculated escaped infection." But so also did the uninoculated, according to the statement, and this for a whole fortnight! This highly irrational proceeding is made to suffice for a summing-up to this effect: "It is too early to be dogmatic, but I am disposed to believe (1) that scarlet fever antitoxin is specific against scarlet fever; (2) that when given intramuscularly in 5 c.cm. doses (of concentrated serum) it protects for at least fourteen days." I think I may safely

challenge the attention of all professed statisticians, and scientists devoting themselves to experimental research, and beg them to tell us what these papers prove, if anything, in connexion with the title that heads them. We want to arrive at a determination of this matter if possible, but those who wish to assist in doing it should avoid, by all means, the creation of an artificial and false estimate of the circumstances attending scarlet fever occurrences to suit the occasion, and then, having applied antitoxin, claim to have stayed the imagined forecast as if an actuality.—I am, etc.,

J. H. GARRETT, M.D., D.P.H.,  
Medical Officer of Health, Cheltenham.

July 23rd.

#### CARCINOMA OF THE PROLAPSED CERVIX.

SIR,—Dr. W. E. Fothergill always writes interesting letters, but I do not think it can be maintained that the rare association of cervical carcinoma and prolapse is due to a fixation of the cervix by the parametria because of cancerous invasion. Descent and protrusion of the anterior vaginal wall and adjacent part of bladder, the appearance of a "cystocele," is usually the first event in "prolapse"—not of the cervix. Other conditions, as Dr. Fothergill mentions, are seldom seen with prolapse—for example, complete rupture of the perineum and pelvic cellulitis. But Dr. Fothergill does not refer to the cause of the visceral retention in the former case; and, omitting to consider the effect of the rest in bed, and the possible chronic invalidism of the patient in the latter, imputes it to a fixation of the uterus. But even when the body of the uterus is fixed, for example, to the abdominal wall by operation, if the causes of "prolapse" are present, then with a return to active life the prolapse recurs.

Dr. Fothergill's reference to the possible existence of malignant disease of the uterus, in patients suffering from prolapse, *qua* the treatment of the latter, is more important. His high amputation of the cervix must remove any cancerous nidus in the cervix; and removal of the cervix, from the point of view of preventing a future cervical carcinoma, whether we be dealing with the prolapse or any pathological state of the uterus (for example, fibroids), is certainly the ideal. Thus, panhysterectomy, instead of subtotal hysterectomy, for the latter condition, should always be done—as Herbert Spencer for years has taught us. But Dr. Fothergill, in dealing with prolapse, is content, *qua* the body of the uterus, with curettage. Three times he has found early unsuspected cancer of the body of the uterus; and on each occasion performed the radical operation—removing, I suppose, as much as he could of the parametric tissue, and leaving—I wonder what—for the "suspension" subsequently of the remaining pelvic viscera, and the "bearing-down" intestines now occupying the uterine space.

In women near the climacteric with prolapse I amputate the cervix as high as I can, slit up the anterior vaginal wall, separate its lappets from the prolapsed part of the bladder, cut through into the vesico-uterine pouch of peritoneum, push up the bladder, and bring down the uterine body. I then push a knife through the fundus, at the summit of the uterus, into the uterine cavity, cut away most of the anterior uterine wall, so that one has exposed the endometrium lining the posterior uterine wall, and at the sides of this shelving stretches of the uterine wall. The endometrium of the posterior wall is then removed, bleeding vessels secured by under-stitching, and the remnant of the uterine body stitched to the anterior vaginal wall, which is sewn up after its redundancies have been excised. It is a modified interposition operation, not before described, I believe, in this country; though the late Dr. Watkins of Chicago seems to have practised a similar operation. A small posterior colpo-perineorrhaphy, in which the levator borders are brought together, completes the operation.

I did this modified operation—which must disclose any present carcinoma and prevent the rise of any future one from the endometrium—for the first time on December 10th, 1923. The patient was 50, and had complained of bearing-down pains for sixteen years and had had the prolapse protruding for four years. When I first saw her

she had had bleeding for ten weeks without intermission. No carcinoma was found. I have repeated this operation since on a few occasions. Dr. Fothergill, I understand, however, does not believe in, at least does not practise, the interposition operation. If he did, and removed the endometrium, I think he would be more assured *qua* the existence of uterine carcinoma and more happy as to its possible future rise; and as regards the prolapse itself would recognize the most excellent results obtained from it.—I am, etc.,

Rugby, July 24th.

R. H. PARAMORE, F.R.C.S.Eng.

#### GLYCOSURIA AND ARTIFICIAL SUNLIGHT.

SIR,—Dr. Barrowman, in your issue of June 12th (p. 990), calls attention to the undue susceptibility of a case of chronic impetigo with glycosuria to ultra-violet radiation, and is evidently under the impression that the glycosuria was responsible for this susceptibility. Out of a series of fifty-five cases of diabetes treated in the "light" department here, none showed any undue reaction, even when associated with impetigo boils or pulmonary tuberculosis. Glucose therefore does not appear to act as a sensitizer to ultra-violet rays, although it has been claimed that it is a sensitizer to x-rays (Professor Holzknecht, *BRITISH MEDICAL JOURNAL*, April 3rd, p. 634). If a complete analysis of the urine had been made, some sensitizer such as haematoporphyrin might have been discovered (Professor Dixon, *BRITISH MEDICAL JOURNAL*, September 19th, 1925, p. 499). Continental workers have called attention to the association of hyperglycaemia and skin diseases, and it is suggested that the mere presence of impetigo in an adult should have called attention to the glycosuria and not the reaction to the ultra-violet rays.

The rapid effect of ultra-violet radiation on impetigo has been reported by Goodman (*Physical Therapeutics*, March, 1926) and by P. Chatin (*Médecine*, Paris, August, 1925). Several cases of impetigo and boils amongst the fifty-five cases of diabetes cleared up rapidly, although the conditions had persisted in spite of insulin treatment since 1923. Most of the cases relapsed, however, one to two months after the ultra-violet radiation had been stopped.

The effect on the general condition noted by Dr. Barrowman is also confirmed by our experience, so much so that a course of light treatment is becoming a routine for diabetics with us. R. D. Lawrence (*BRITISH MEDICAL JOURNAL*, April 10th, p. 648) shows that a diabetic on insulin may actually go into a state of hypoglycaemia after vigorous exercise. As ultra-violet radiation is said to increase the rate of metabolism, one would expect a lowering of the blood sugar after radiation. A long series of tests on diabetics, in collaboration with Drs. Willmore and Vatcher, has so far failed to confirm this. In some cases the blood sugar was lowered, in others there was no effect, while in a number of cases it was raised. A. Laqueur and H. Wiener, however (*Medizinische Klinik*, February 13th, 1925, vol. 21), seem to have obtained more definite results, for they state definitely that ultra-violet radiation tends to lower the blood sugar content in the diabetic.

Although we have failed to observe any definite effect of ultra-violet radiation on the blood sugar, we have no doubt of the value of ultra-violet radiation as a general tonic in the diabetic, quite apart from its effect on local skin lesions.—I am, etc.,

M. WEINBREN.

Queen's Hospital, Fognal, Sidcup,  
Kent, July 24th.

#### OBSTRUCTION AT THE VESICAL OUTLET AFTER PROSTATECTOMY.

SIR,—I read Mr. W. K. Irwin's article on obstruction after prostatectomy (July 3rd, p. 10) with great interest. In each of his three cases he had diagnosed a fibrous type of enlargement of the prostate and experienced much difficulty in its removal. This is the variety that in my opinion calls for perurethral removal by diathermy, preferably applied through a Canny Ryall operating cystourethroscope, and not by suprapubic prostatectomy. The

results obtained by the former method are excellent, never leading to subsequent contraction and not interfering with the patient's occupation.

Post-operative obstruction can be readily and painlessly treated by intermittent dilatation with a curved Kollmann's dilator at weekly intervals after preliminary anaesthesia of the urethra. Treatment should be continued until the vesical neck and posterior urethra attain a calibre of 45 French, when the intervals are gradually increased.

Finally, post-operative obstruction may to a great extent be prevented by the routine packing of the prostatic cavity with gauze for forty-eight hours after enucleation of the prostate and the early passage of the catheter.—I am, etc.,

J. C. AINSWORTH-DAVIS, M.B., F.R.C.S.E.,

Assistant Surgeon, All Saints' Hospital.

London, W.1, July 7th.

### MIDDLE-EAR DEAFNESS.

SIR,—In your issue of June 26th (p. 1087) a paper read by Mr. W. C. Stevenson and Mr. T. G. Wilson at the Royal Academy of Medicine in Ireland is reported, in which it is stated by Mr. Wilson that chronic hyperplastic otitis media and oto-sclerosis were fully discussed at the British Medical Association meeting at Bath last year. I would point out that oto-sclerosis was specifically excluded from this discussion.

It is further stated that at this meeting treatment was universally admitted to be most unsatisfactory. In this connexion I would draw attention to the fact that my contribution to the discussion, as reported in your issue of December 12th, 1925, stated that the results of treatment as carried out by me for middle-ear deafness were highly satisfactory, and in the afternoon of the same day a number of cases were shown to illustrate the good results of this treatment, carried out in patients of all ages in whom deafness had been present to a marked degree, and most of whom had had the treatment some years prior to the meeting.

Messrs. Stevenson and Wilson are to be congratulated on treating this most important disability in another and new way, and the results reported are most interesting.—I am, etc.,

Bath, July 6th.

H. NORMAN BARNETT.

### ST. KILDA.

SIR,—Your article on St. Kilda (July 10th, p. 80) was particularly interesting to any who had visited the island.

Two years ago, whilst on holiday, I was asked to see their sick and had opportunities of observing the actual home conditions, going into nearly every house. The sick rate was very high; I examined about twenty, but they had had no opportunity of consulting a doctor for nine months. I remember cases of rheumatism, bronchitis, heart disease, and a case with signs of tuberculosis (but I had no facilities for sputum examination), scabies, and indigestion, of which two cases were no doubt gastric ulcer. The most striking defects were dental caries and constipation, due without doubt to vitamin deficiency. Although in accounts of the islands their diet is described as consisting of mutton, bread, milk, cheese, salted fulmar, eggs, etc., I was told that the food of most in the winter consisted of "salted bird" chiefly.

Some provision for dental treatment was greatly needed. They had a very fine nurse, but she was badly handicapped for want of some simple drugs, like vegetable aperient pills and cod-liver oil. She was expected to manage nearly everything with castor oil. The quantity of milk was not sufficient. There is no doubt the presence of such a woman had a great psychological as well as material effect. She treated sick and sound like children, as their mentality deserved, for they appeared child-like in their dependence. It would be interesting to know whether the initiative of emigrants increased as their mental horizon widened.

In regard to the etiology of the tetanus of the past, noteworthy points are:

1. In view of horse dung being considered a common source of this disease, the absence of such from the island is interesting; but, of course, highland cattle, sheep, and a very large number of dogs might provide an origin.

2. The floors of some of the houses consisted of earth or, if bricked or paved, such a flooring was covered by dirt. One patient expectorated freely on the floor as he stood in the room which was the living room for the family.

3. The fulmar oil dressing to the umbilicus which has been supposed to be the source of the tetanus would afford an excellent anaerobic chamber, just like a blood-soaked first field dressing in war time, or as gutta-percha tissue will cause anaerobic organisms to grow freely. Vaseline spread on lint would have been equally effective in producing such conditions for the cultivation of the bacillus.

—I am, etc.,

Thornton Heath, July 16th.

G. W. LLOYD.

### THE ARMY MEDICAL SERVICE.

SIR,—The strenuous efforts of the British Medical Association's committee are proving of value, but candidates will do well to examine the report published in your issue of January 30th, and to ask their experienced friends to indicate the points of importance still undealt with by the War Office. My letters published on May 2nd and August 8th, 1925, will help them. Especially should they consider two points. One is as to whether the new terms apply to India. If not, it is unsound to think of joining; and there are many other points to be settled as regards India, where officers of the Army Medical Service serve more than anywhere else. The other main point is to be sure that officers will have free play in their work, as without this any intellectual man will find he is living a hopeless, hidebound kind of life. The desired result will be attained only when the Director-General is upon the Army Council, and the Army Medical Service is reconstituted as a branch of the army as separate as the Adjutant-General's or the Quartermaster-General's. To this end all the efforts of the British Medical Association should now be directed. The A.M.S. could then serve the army efficiently, and without the daily obstructions and vexations officers must encounter who keep on the top level of medical science, and yet cannot adequately express their views, knowledge, and convictions. I trust that this idea will be promulgated elsewhere in the public eye. Meantime, that is the main objective, and candidates should be careful not to be led away by seductive monetary advantages that may prove as ephemeral as they have in the past. Ideal service in the army is still only in the making.

I should like to thank correspondents for the letters they have written to me. I have been quite unable to acknowledge them all.—I am, etc.,

Junior United Service Club,  
S.W.1, July 16th.

T. M. CORKER,  
Major-General.

### DEFENCE OF ASSISTANTS AND LOCUMTENENTS.

SIR,—The councils of the Medical Defence Union, Ltd., and the London and Counties Medical Protection Society, Ltd., have agreed that each society will defend a member in an action arising out of the acts or omissions of an assistant or locumtenent who is a member of the other society, as if the assistant were a member of the same society as the principal, and similarly in the case of actions against members on the staff of hospitals against whom actions are brought arising out of the acts or omissions of duly appointed subordinate medical officers.

We shall be grateful, therefore, if you will kindly publish this letter so as to bring this arrangement to the notice of the medical profession generally.—We are, etc.,

JAMES NEAL,  
General Secretary, Medical Defence  
Union, Ltd.

HUGH WOODS,  
General Secretary, London and Counties  
Medical Protection Society, Ltd.

London, July 23rd.

## Obituary.

**A. REITH FRASER, M.D. ABERD.**

Lecturer on Venereal Diseases, Capetown University.

ON July 10th the death of Dr. Archib Reith Fraser of Plumstead, South Africa, was announced by cable. Dr. Fraser, who was 36 years of age, was educated at the Grammar School, Aberdeen, and graduated M.B., Ch.B. at Marischal College early in 1914. In August of that year he took a temporary commission in the R.A.M.C. He served in France until invalided after the battle of Neuve Chapelle in 1915. On his return to duty he was with the 1st Scottish General Hospital, and later at the Scottish Command Venereal Hospital, Robroyston. He had a wide

and varied experience in the treatment of venereal diseases in these army hospitals, and his clinical and administrative abilities marked him out from the beginning. He was energetic as well as original and resourceful; all these characteristics are well shown in the papers he contributed to the medical journals and in his monograph on gonorrhoea.

In 1919 he took the M.D. degree at the University of Aberdeen, with distinction for his

thesis; in the following year he went to South Africa as a venereal specialist to the Union Government. In a few months his health broke down, and he resigned to take up the appointment of university lecturer in venereal diseases at Capetown University. Here, again, he continued to work too hard. He was honorary secretary to the Cape of Good Hope (Western) Branch of the British Medical Association, and he did most valuable work for it and the profession.

He had a charming personality, although he was down-right and outright to a degree. He was a good speaker as well as an easy writer, and a caricaturist of the first water. The profession is the poorer in the loss of such a promising and able—indeed brilliant—member. He was always ready to go out in defence of the "under-dog" against all the world, and he has restored countless numbers to self-respect and self-help—in some cases kindled an inspiration where it seemed an utter impossibility. He was a very practical Christian. He leaves a widow and two children.

Dr. ALFRED COX, Medical Secretary, British Medical Association, writes:

Dr. Reith Fraser was one of the most successful honorary secretaries the British Medical Association has ever had, and was, in addition, a very brilliant and attractive personality. He radiated vitality all round him. To me he was very kind and attentive during my visits in the area of the Cape of Good Hope (Western) Branch, and he took an active part in furthering the object of my tour in South Africa. His loyalty to the Association, his tremendous enthusiasm, energy, and organizing capacity, will all be greatly missed by his colleagues in Capetown. But I am sure they will think even more, as I do, of the loss of the man, the eager, vivid personality, at the outset of a brilliant professional career; and of his wife and young family and his parents, to whom their and my heartfelt sympathy goes out.

**R. H. STEEN, M.D., F.R.C.P.,**  
Formerly Superintendent, City of London Mental Hospital,  
Dartford.

WE regret to record the death, on July 12th, of Dr. Robert Hunter Steen, who was for over twenty years medical superintendent of the City of London Mental Hospital, Dartford, Kent. He was born in Belfast in 1870 and was educated in that city, graduating B.A. in the Royal University of Ireland in 1891; afterwards he became a student of St. Mary's Hospital, London, and graduated M.B.Lond., with honours in medicine, in 1894. After serving as house-physician at St. Mary's Hospital and at the Brompton Hospital for Consumption he determined to devote himself to psychiatry; he held the post of assistant at the West Riding Asylum, Wakefield, and at the West Sussex County Hospital, Chichester, before his appointment to Dartford in 1905; four years later he became professor of psychological medicine in King's College, London, and was subsequently appointed out-patient physician in psychological medicine to the hospital. When he retired from Dartford in 1925 he was elected emeritus professor. He graduated M.D.Lond. in 1896; he became M.R.C.P. in 1913, and was elected F.R.C.P. in 1921. He was a member of the British Medical Association; he was secretary of the Section of Psychological Medicine and Neurology of the Annual Meeting held in London in 1910, and chairman of the Dartford Division for 1911-12, and again in 1919; he was vice-chairman in 1913 and 1920, and a member of the executive committee of the Division from 1914 till 1918. He was also a member of the Royal Medico-Psychological Association and had been its honorary general secretary. He contributed a number of papers to its organ the *Journal of Mental Science*, including articles on moral insanity (1913), hallucinations in the sane (1917), and chronic hallucinatory psychosis (1920). In the paper last named he argued that there were cases of this type which could be grouped together, and discussed with acumen the differential diagnosis. He attached great value to the establishment of special out-patient departments at teaching hospitals, believing that through them students would gain a knowledge of the main facts of psychological medicine and so be better able after they went into practice to diagnose disorders of the mind at an early stage.

As an administrator he was very successful, holding and expressing views as to the treatment of patients which, when he first adopted them, were perhaps rather in advance of the general opinion among his colleagues. He was anxious that neither the profession nor the public should look upon asylums as mere places of confinement, but rather regard them as hospitals in which the cure of a considerable portion of the patients might be expected.

**ERNEST HENRY HOUTON, M.D.,**

Honorary Surgeon, Mansfield Hospital.

Dr. ERNEST HENRY HOUTON, who died on July 4th, aged 54, was educated at Leeds University, where he gained the entrance medical scholarship in 1889, the junior silver medal in 1889-90, and the Thorp prize for forensic medicine in 1892. In the following year he obtained the diplomas M.R.C.S., L.R.C.P., and in 1894 graduated M.B., B.S.Lond., with honours in obstetrics; he proceeded M.D. in 1899. After holding the appointment of resident obstetric officer to the Leeds General Infirmary he commenced practice in Mansfield in 1903. He was honorary surgeon to the Mansfield Hospital and medical officer of health for the Mansfield-Woodhouse Urban District Council. He took an active interest in the Nottingham Division of the British Medical Association; he was a representative in 1913-15 and a deputy representative in 1918-20 and 1925-26. He was vice-chairman of the Division in 1920, and was a member for many years of the Contract Practice Subcommittee of the Medico-Political Committee, and of the Midland Branch Council. He was a member of the Consultative Council on Medical and Allied Services and secretary of the Notts Panel Committee.

We have received the following tribute to Dr. Houlton from two of his colleagues: Dr. Houlton was a busy and successful general practitioner and an accomplished surgeon. There is no doubt that if he had devoted himself to surgery in his younger days he would have won eminence in that direction. In spite of the pressing demands of a large practice he devoted much time to the service of his fellow practitioners. About twenty-five years ago he was concerned in the formation of the Midland Medical Union, an association whose main purpose was to organize the general practitioners of Notts and Derbyshire. Much useful work was accomplished until the union ceased to function on the reconstitution of the British Medical Association, the members transferring their energies to the development of the Divisions of the Association. From that time Dr. Houlton was a thorough "B.M.A. man." He had been chairman of the Nottingham Division, and he served as representative during the stormy days preceding and following the passing of the National Health Insurance Act. He was also a member of the Nottingham Insurance Committee, and had served the Local Medical and Panel Committee continuously in the position of secretary, also the Contract Practice Subcommittee of the British Medical Association, and was afterwards appointed to the Consultative Council under the then Minister of Health. Much of his time in latter years was spent in the interest of the Mansfield Accident Hospital, where, in addition to his active work as a surgeon, he was always ready to help the board of management with his advice while the hospital was being enlarged. The colliery surgeons of Notts and Derbyshire will always remember Dr. Houlton with the deepest gratitude for his untiring efforts on their behalf in their many negotiations with the colliery clubs. Only those closely associated with him in this work can appreciate the devotion with which he laboured for the benefit of his fellow practitioners. He never spared himself in the service of his patients or of his professional brethren, and his death at the early age of 54 is a serious loss to the community and to the profession.

#### ROBERT HENRY CLARKE, M.A., M.B.,

Late Demonstrator of Physiology, St. George's Hospital.

DR. ROBERT HENRY CLARKE, whose death in Paris, on June 22nd, we regret to record, had retired from practice for many years, and had devoted himself to physiology and research work. He was born on October 9th, 1850, the son of Thomas Clarke, senior member of the Board of Revenue and member of the Legislative Council of Madras. The son was educated privately and at Queen's College, Cambridge, and entered St. George's Hospital in the winter session of 1872. He obtained the diploma M.R.C.S. in 1876, and graduated M.A. Cantab. in 1882 and M.B. four years later. He was house-surgeon to the Western Infirmary, Glasgow, and later demonstrator of anatomy at Glasgow; he returned to St. George's Hospital as demonstrator of physiology in 1885 and held this post for two years. In his younger years he was a prominent athlete; he represented his college at cricket and football, and rowed in the Queen's boat. While at St. George's he was a member of the hospital Rugby fifteen.

Clarke's latter years were devoted to physiological research; most of his work was done in the laboratories of University College Hospital with Sir Victor Horsley. Clarke's stereotaxic instrument was a splendid piece of apparatus which has hardly received the attention in this country that its importance warrants. For accurate localization in the laboratory it is well-nigh indispensable: the instrument was purchased some years ago by the Johns Hopkins University. He was the joint author with Horsley of several papers in *Brain* on the structure and functions of the cerebellum. His chief contribution to literature was his atlas of sections of the brain of the cat and monkey, which was published in the *Journal für Psychologie und Neurologie* in 1911. In this work he was greatly assisted by Mr. E. Erskine Henderson, who was responsible for all the illustrations. His home of late years was

at Wallington and later at Croydon. Though he was known to be in feeble health, his death came as a great shock to his many friends.

We are indebted to Sir G. R. TURNER for the following appreciation:

Dr. R. H. Clarke had one of the best all-round intellects that I have ever come across. He did an enormous amount of original work for which he did not get adequate credit. He was the inventor of the stereotaxic instrument which bears his name, and by which any nucleus in the brain of a cat or monkey could be reached with absolute accuracy, without the shock of trephining, and stimulated or destroyed by needles without risk to surrounding structure. In this way experimental research on the brain or cerebellum has been much facilitated. Much of his work on the latter has not as yet been published; there is, however, a paper in four chapters, entitled "The divisions of the cerebellum and their relation to function," in the hands of his executor.

He wrote a book on roaring in horses, and devised an ingenious operation of stitching up the aryteno-epiglottidean fold of mucous membrane for its cure. This he practised with success on several broken-down hunters, one of which had been hunted by the late Empress of Austria. He found out many micro-organisms which caused diseases in birds. In the nineties of last century, when he was in Egypt, he made numerous experiments with different coloured thermometers with reference to sun heat, and showed that pigmentation in man, though it lessens resistance to sun heat, is very efficacious against the evil effects of sun light. He was the first, or one of the first, to publish this fact. He was a great psychologist, and believed implicitly in telepathy. He was a very good subject himself, and the late Mr. Capper and he had extraordinary success in thought reading.

He was an excellent sportsman—a very good man to hounds and judge of a horse; devoted to hunting, he never cared about racing. He was a good shot, a good cricketer and golf player, and a charming companion beloved by his many friends of all ages.

#### ANDREW RAE WRIGHT, D.S.O., M.B., B.Ch.,

Brevet Lieutenant-Colonel R.A.M.C.

THE death of Brevet Lieut.-Colonel Andrew Rae [Wilbur] Wright, on June 30th, at the General Hospital, Madras, from appendicitis, has cut short a career of considerable promise. He was born at Wigan in 1881, and was the younger and only surviving brother of Professor William Wright, Dean of the London Hospital Medical College. He received his professional education at Owens College, Manchester, and graduated M.B. and Ch.B. in 1904. After holding the appointments, among others, of house-physician at the Manchester Royal Infirmary and senior resident medical officer at the infirmary, Crumpsall, he joined the R.A.M.C. in 1908. Stationed at Malta when the war broke out, as regimental medical officer to the 2nd Battalion of the Royal Warwickshire, he disembarked at Zeebrugge on October 6th, 1914, and took part in the memorable rearguard action fought by the Seventh Division around Bruges, Hansbeke, Ghent, Thielt, Roulers, and Menin. On December 31st he was posted to command "C" Section of the 21st Field Ambulance, and on April 19th, 1915, to be second in command of No. 10 Casualty Clearing Station at Hazebrouck. When it was decided to introduce the practice of pitching casualty clearing stations on open ground, without buildings of any kind, the 10th Casualty Clearing Station was chosen for the experiment, being placed at Rémy Siding, near Poperinghe. He remained there for some time, serving, as Major-General Sir Anthony Bowlby writes, "with great credit, a most zealous and capable officer, and a first-rate organizer." He was several times mentioned in dispatches, and received the D.S.O. Later he served on the staff. For his services in the rearguard action leading up to the first battle of Ypres he received the decoration of the Belgian Croix de Guerre. At the close of the war he became personal

assistant to the Director-General of Medical Services, and later acted in a similar capacity to the adjutant-general, being, we believe, the first officer of the R.A.M.C. to hold this position. For his services in these posts he received the rare distinction of being, while still a captain, gazetted brevet lieutenant-colonel on promotion to major. In 1921 he proceeded to India, serving on the staff at Simla, and later commanding the British Station Hospital at Roorkee. Returning to England in October, 1925, he was posted D.A.D.M.S. to the British Army on the Rhine, and was one of the last to leave Cologne when the army moved south to Wiesbaden. Early in the present year he returned to India, and had just taken up the appointment of senior medical officer at the British Station Hospital, Madras, when he was stricken down with appendicitis, which unhappily proved fatal in the afternoon of June 30th.

A man of commanding presence, he gave an impression of strength and power, which was still further accentuated by his imperturbable composure. Reserved and seemingly austere on first acquaintance, his manner rapidly thawed when, as so often happened, acquaintance ripened into friendship. He was gifted with a refined sense of humour; one of his most successful sallies was commemorated in the *nom de corps* of Wilbur, by which name he was almost universally known. Devoted to the army and punctilious in attending to his duties, he yet found time to become well informed on most subjects and to develop a no mean musical talent. Geniality, modesty, and sympathy were the outstanding features in a very attractive personality. With his natural gifts and varied experiences he seemed destined for positions of still greater influence and honour than those he had already held. It was, however, not to be.

**HELEN BEATRICE DE RASTRICKE HANSON, M.D.,**  
B.S.LOND., D.P.H.Oxon.,  
Assistant Medical Officer, Public Health Department,  
London County Council.

WE regret to announce the death of Miss Helen Beatrice de Rastricke Hanson, who was killed in a motor-car accident on July 6th, at the age of 52. Miss Hanson received her medical education at the London (Royal Free Hospital) School of Medicine for Women, where, in 1901, she obtained the diploma L.S.A. and graduated M.B. Three years later she proceeded M.D. and B.S., and in 1911 she took the D.P.H.Oxford.

After three years in India, where she was medical officer to the Kinnaird Memorial Hospital, Lucknow, she was appointed assistant school medical officer to the London County Council. When war broke out she became attached to the British Red Cross Society and the St. John Ambulance, and went with Mrs. Stobart's unit to Cherbourg and afterwards to Serbia. In 1916 she published in the *Journal of the Royal Society of Arts* an article entitled "Serbia as seen by a Red Cross worker." She was transferred to the R.A.M.C. in 1916, and served first in Malta and later in Salonika. After the armistice she went with the Black Sea Expeditionary Force to Constantinople, and subsequently returned to her post as school inspector. She was a member of the British Medical Association, the Medical Women's Federation, and the Federation of University Women. Since 1910 she had served on the committee of the League of the Church Militant, and for the last few years had been honorary treasurer. She was buried on July 12th at Finchley, and a requiem service was held in St. Martin's-in-the-Fields on July 20th.

We are indebted to Professor LOUISE McILROY for the following note: In a circular letter issued by the chief of the London County Council medical department acquainting the members of the staff with the news of her death by an accident, reference was made to Dr. Hanson as "our beloved colleague." This was no empty saying, but a sincere expression of the sentiment with which she was regarded by those with whom she came in daily contact. She was most unobtrusive and humble-minded as regards her own attainments, but always first in paying tribute to the worth of others. High and low, rich and poor, young and old, pious and worldly, alike found in her

a staunch friend. The blank that is left will not be realized immediately. It is only from day to day, when her loving energetic presence is no longer with us, that we shall truly miss her. Her work as a school medical officer brought her into touch with parents and children of all social grades, with teachers, nurses, and doctors, by all of whom she was greatly esteemed. However monotonous her daily routine, she never seemed to get tired or bored. A large circle of devoted friends, in addition to those immediately connected with her work, show her wide social interests. Her broad human outlook, sound judgement, and boundless sympathy were always at the disposal of her friends. Her service in the war, when she was temporary medical officer R.A.M.C. from 1916 to 1920, and her courage in the face of danger, were well known to those who were with her in the East. Her tragic end in the midst of her work came as a shattering blow to all who knew her. The sympathy of her friends goes out to her mother and sister, who lived with her, but they have the consolation of a great pride in the memory of one who was indeed a very noble woman.

**Dr. JAMES SMITH**, who died on June 30th, at Putney, received his medical education at Cambridge and St. Thomas's Hospital, where he was distinguished for his athletic attainments. He was a University Rugby Blue, and was also a very good tennis player. He won a science scholarship at Jesus College, Cambridge, and in 1895 he graduated M.B., B.Ch., and obtained the diplomas M.R.C.S., L.R.C.P.; in the following year he became F.R.C.S. After holding the posts of house-surgeon at St. Thomas's Hospital, assistant resident medical officer at the Queen Charlotte's Maternity Hospital, and clinical assistant to the Evelina Hospital for Sick Children, he built up a very large practice in the neighbourhood of Putney, where his untiring devotion to his patients won him great popularity.

**Dr. EDWARD H. HUGO**, who died on July 17th at Crediton, Devon, was born at Gillingham, Kent. He was the eldest son of the late Dr. E. H. Hugo, and was educated at Epsom College and Charing Cross Hospital Medical School. He graduated M.B., B.S.Lond. in 1897, and held the posts of house-physician and house-surgeon at Charing Cross Hospital. After a tour round the world he commenced practice at Bodmin, and was appointed surgeon to the East Cornwall Hospital, and medical officer of health for the borough of Bodmin. He was honorary secretary of the East Cornwall Division of the British Medical Association. On the outbreak of war he took a commission as temporary surgeon R.N., and served at Gibraltar, Gallipoli, and the Shetlands. After the war he returned to practice in Bodmin, but owing to ill health had to retire in October, 1925. He is survived by his widow and one daughter.

The late **Dr. ERNEST G. B. STARKIE** was educated at Edinburgh University, where he graduated M.B., C.M. in 1889, and took the degree of M.D. (with commendation) in 1904. He started practice in Poulton-le-Fylde, where he was medical officer of health, but after a few years settled in the suburb of Moseley, Birmingham. His forceful character and earnest purposeful devotion to his work soon made him a very successful and popular practitioner, and enabled him to command the confidence of a very large circle of patients and friends. In 1915 he deemed it his duty to offer his services to the R.A.M.C., and was sent to Malta, where he was able to do much valuable surgical work. Unfortunately, he there fell a victim to dysentery, which left its mark upon him, encouraging in some degree the fell malady the development of which brought about his lamented death. These lines are written by one who was closely associated with him in practice for over eighteen years, as a slight tribute to his memory and in acknowledgement of many pleasant hours spent in his company.—A. B.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons will rise on August 4th, or at latest August 5th, for the recess, and will reassemble for ordinary business about the beginning of November. There may be special sittings earlier to renew the Emergency Regulations. This week the House has discussed the mining dispute, the Mining Industry Bill, and the renewal of the Emergency Regulations for August. All outstanding Estimates have been voted, including that for the Ministry of Health.

The Parliamentary Medical Committee met on July 28th at the House of Commons.

In consequence of the elevation of the Secretaryship for Scotland into a Secretaryship of State, Dr. Walter Elliot, previously Parliamentary Under Secretary of Health for Scotland, has been appointed Parliamentary Under Secretary of State for Scotland.

Dr. Drummond Shiels has been selected as a member of the parliamentary delegation to Australia in place of Mr. William Adamson.

In the House of Lords, on July 27th, the Mental Deficiency Bill was, on the motion of Viscount Gage (Lord in Waiting), read the third time, and passed. The Chartered Associations (Protection of Names and Uniforms) Bill was also read the third time, and passed.

Consideration of the Coroners Bill in Grand Committee of the House of Commons was due to commence on July 27th, but, no quorum appearing, the Committee was postponed.

The Births and Deaths Registration Bill came up on report on July 27th, and was postponed till August 4th. On the same day the second reading of the Venereal Disease Act Amendment Bill, and of the Dentists Bill, was further postponed.

Against the University of London Bill, which had come down from the Lords and had been entered for second reading in the Commons on July 28th, a motion for rejection was tabled by Dr. Graham Little, Sir Murdoch Macdonald, Mr. Atkinson, and Commander Kenworthy.

On July 22nd Dr. Graham Little presided over a meeting of peers and members of Parliament in a committee room at the House of Commons, when addresses against the University of London Bill were delivered by Lord Justice Atkin, Sir William Collins, and Professor Loney, members of the Senate. Sir William Collins said the University was not effete, corrupt, or unsuccessful; the changes proposed by the bill would imperil the future of the University. Other speakers objected to the proposal that the independent members of the Senate should be eliminated.

### The Mental Deficiency Bill.

In the House of Lords, on July 22nd, the Mental Deficiency Bill was read a second time without a division. Explaining the bill for the Government, Viscount Gage said that the most important provision was in Clause 1, where the definition of a mentally defective person was altered and extended to include persons affected by injury or disease since birth or early age. There were cases where some injury or disease, particularly encephalitis lethargica, produced a condition analogous to innate mental deficiency. Under the existing definition it was impossible to certify these individuals as mental defectives owing to the inclusion in the original statute of the words "from birth or from an early age." Under this bill these persons could be attended to in the proper kind of mental home. The next most important provision of the bill was that a local authority might build a larger institution than it required for itself and take cases by contract from other local authorities. An institution with from 500 to 1,000 places was more efficient as well as more economical than a smaller institution. Another provision allowed the local education authority and the mental deficiency authority—both committees of the one council—to provide a joint institution should they deem that desirable. This clause had the approval of the Board of Education. Other clauses merely made small administrative changes which had been found desirable. The bill had been very thoroughly investigated by a committee on which leading specialists on the subject were represented as well as the medical members of the House of Commons, and he understood that it had their entire approval.

The Mental Deficiency Bill formally passed through Committee on July 26th, and was reported without amendment.

### India.

Earl Winterton (Under Secretary for India), in introducing the India Office Vote, on July 20th, referred to the decision of the Government of India to extinguish exports of opium, except for medical and scientific purposes, by progressive annual reductions of

10 per cent. during ten years. Since this policy had been announced resolutions in support of it had been passed by both Chambers of the Indian Legislature. This decision, which was taken with the hearty concurrence of the Secretary for India, was the culmination of a series of measures, taken over many years past, for the regulation and restriction of the export of opium from India. The overcrowding and disease which followed in the wake of industry in some Indian cities must be deprecated, and no efforts should be spared to better those conditions. Enlightened industrialists in India had developed many excellent housing schemes, and he hoped this good work would continue, but the will to take advantage of better conditions did not always exist, and only education could create that will. The army manoeuvres showed that as regards physical fitness and training the men were quite fit to take the field, but a good deal more had to be done before the army could be said to be properly housed in barracks. The bulk of the recommendations of the Lee Commission with regard to the Civil Service, including those of a financial character, had been implemented. The Public Services Commission had been appointed, and the chairman had already gone to India; the Commission would meet on October 1st.

Mr. Scurr, while welcoming the decision of the Government of India with regard to the export of opium, objected to its attitude in refusing to prohibit its use in India.

Sir G. Butler said that there was much that could be done by British people in this country and in India, attached to the Government, to help on progress in the various transferred subjects. In the medical, scientific, industrial, and agricultural research fields it would be wrong to put these transferred services into watertight compartments. He asked what relation existed between the scientific and technical activities of the Government of India and those of the Provincial Governments. What were the relations between the central officials and the various technical officials in the public health departments of the Provinces? Was the central organization going to fade out of the picture? The importance of scientific work in the future development of India could not be exaggerated. Those who wanted to conduct experiments in physiology, and into various forms of disease, and so forth, could not wish for a better field of work.

Dr. Haden Guest said that the outstanding fact of the Indian people was not its prosperity, but its poverty, which was increasing. This was the basic reason of all the troubles in India. The average length of life of the ordinary person in India was about twenty-three years, as compared with forty-five years in Great Britain. The infantile mortality rate reached, in certain industrial areas, between 60 and 80 per cent. Something could be done to raise the standard of life in India by reviving the old village organizations. The standard of life in India was at most only half as good as in England. Many of the thousands of India were living on a diet which was starvation even in the ordinary times.

Brigadier-General Clifton Brown disagreed with Dr. Haden Guest as to the physique of the people of India. He wished the hon. member could go to the Punjab and see some of the Sikh regiments, than whom no finer men physically could be found. Dr. Haden Guest said he had seen the Sikh regiments in Palestine, and he agreed that they were very good, but he had read the medical and social statistics of India, and that was the point.

Brigadier-General Brown said that the climate of India made matters very difficult for any medical officer. Plague alone carried off hundreds of thousands every year, and hundreds of British lives had been lost in trying to stop it. If it had not been for the British Government more Indian lives would have been lost from starvation and hunger.

The vote was agreed to.

**Maternity and Infant Mortality.**—On July 26th Mr. Chamberlain (Minister of Health) informed Mr. Rhys Davies that the death rate of women in childbirth, the birth rate, infantile mortality, and mortality of persons from tuberculosis in all forms in England and Wales for 1923, 1924, and 1925, was as follows:

|  | England (excluding Monmouth). |       |       | Wales (including Monmouth). |       |       |
|--|-------------------------------|-------|-------|-----------------------------|-------|-------|

**Birth Rates in Metropolitan Boroughs.**—On July 20th Mr. Chamberlain furnished tables, in reply to a question by Sir William Davison, which showed that in the metropolitan boroughs of London the birth rate per 1,000 population was 29.0 in 1901, 24.7 in 1911, 18.6 in 1924, and 17.9 in 1925.

**Tuberculosis Dispensaries.**—Asked on July 4th what steps were being taken with a view to the greater utilization of the opportunities provided by the tuberculosis dispensaries, Sir Kingsley Wood replied that the Minister of Health was not clear what further use of the tuberculosis dispensaries Mr. Day had in mind. These dispensaries were provided by the local authorities, and his department had always encouraged their full use as centres for diagnosis, observation, and special forms of treatment.

**Middle-class Nursing Homes.**—On July 19th the Minister of Health told Major Ainsworth that his department had no record of the extension of nursing homes or institutions for the poorer middle class for the use of which payment was made on a modest scale. While he appreciated the need for accommodation of this kind, its provision was a matter for local initiative, and there were no funds at his disposal from which assistance could be given.

**Schools and Playgrounds.**—In Committee on the Board of Education Estimates on July 22nd, Mr. Trevelyan said that in the revised regulations of the Board the detailed building regulations for schools had disappeared. Local authorities were saying they would take advantage of this freedom to go back to the 1914 standard of floor space. What was the objection of the Government to saying, in the case of new schools, that there must be at least so much air space for the children and so much playground space? Dr. Haden Guest said a fundamental defect of the present educational system was that there was so great a difference between the publicly supported type of school and the education of the public schools. The Board of Education might make a large proportion of what were called the public schools available to children from the elementary schools. When he was a medical inspector of schools he frequently noticed that teachers were a very lonely tribe. They never really came into contact with the universities, with other teachers, or with people leading wider lives. The standard of health of the population had been improving. If a high national level of health and a really national system of education were obtained the country would be able to solve its problems. But it all in the nation were to co-operate there must be a common background in the mind of the children, gained through having passed through a common school experience. The Duchess of Atholl said Dr. Haden Guest had exaggerated the gap between public schools and schools provided under the national system. Every day the Board tried more and more to introduce what was known as the public school spirit into the elementary schools. Nothing was more characteristic of education to-day than the desire of every type of person interested in schools to see the children have more opportunities of playing organized games. Dr. Haden Guest said there was not a great opportunity of games in Southwark. Only one acre there was for organized games. At the end of the debate the estimates were passed.

#### Notes in Brief.

On July 20th: Sir L. Worthington-Evans (Secretary for War) informed Brigadier-General Clifton Brown that the number of officers not holding permanent regular commissions still employed with the regular army on July 1st was 152. This number included: Royal Army Medical Corps, 35; Army Dental Corps, 60.

On July 20th Sir J. Gilmour presented a bill to amend the provisions of the Prisons (Scotland) Act, 1877, and it was read a first time.

The Prime Minister sees no prospect of time being found for the passing of the Sale of Food and Drugs Act (1875) Amendment Bill during the present session.

Any agreement reached as the result of the discussions now in progress between representatives of the approved societies and of the dental profession will be submitted, before any action is taken, to the consultative council on approved societies' work, which is the recognized statutory body representative of approved societies.

## The Services.

### ROYAL ARMY MEDICAL CORPS.

#### Obligations of Officers.

AN officer of the Royal Army Medical Corps who undergoes in future the senior course of instruction for captains prior to promotion to major, or a specialist course, will be required to sign an honourable undertaking to continue to serve in the army after the termination of the course for a minimum period of three years. This will not preclude the Army Council from releasing him from his obligation should the circumstances justify release; but an officer who receives permission to resign his commission before the expiration of the period for which he undertakes to serve will be required to join the Regular Army Reserve of Officers.

### NAVAL MEDICAL COMPASSIONATE FUND.

At the quarterly meeting of the directors of the Naval Medical Compassionate Fund, Surgeon Vice-Admiral Sir Joseph Chambers, K.C.B., C.M.G., Medical Director-General of the Navy, in the chair, the sum of £55 was distributed among the several applicants.

### DEATHS IN THE SERVICES.

Colonel James Patrick Rooney, Army Medical Service (ret.), died at Dunkeld on May 23rd, aged 82. He was born on March 22nd, 1843, and was educated in Dublin, where he took the L.R.C.S.I. in 1864 and the L.K.Q.C.P. in 1865, also later the F.R.C.S.I. in 1889. He entered the army as assistant surgeon on March 31st, 1866, and became colonel on July 8th, 1896, retiring on March 22nd, 1905. In the old regimental days he served in the 60th Foot, the King's Royal Rifle Corps. For the last six years of his service he was principal medical officer of the Scottish command.

## Medico-Legal.

### LUNACY CERTIFICATION: THE STATUTE OF LIMITATIONS.

HARNETT v. FISHER.

THE Court of Appeal (consisting of Lord Hanworth, MR, Warrington and Scrutton, L.JJ.) on July 21st dismissed the appeal of Mr. William Smart Harnett from the judgement of Horridge, J., dismissing his action against Dr. Holdrich Fisher of Sittingbourne for damages for alleged negligence in certifying him to be a lunatic and a proper person to be detained under care and treatment.

The case was reported in the BRITISH MEDICAL JOURNAL (April 24th, p. 762, and May 1st, p. 811).

The jury found that Mr. Harnett was not of unsound mind when he was certified by Dr. Fisher, and that Dr. Fisher did not use reasonable care in certifying him, and they assessed the damages at £500. Dr. Fisher had, however, pleaded that the action was barred by the Statute of Limitations, 1623, Sections 3 and 7, and Horridge, J., after hearing legal argument, upheld the plea.

Mr. J. W. J. Cremllyn and Mr. N. L. C. Macaskie (instructed by Mr. H. Coulson) appeared for Mr. Harnett, and Mr. Neilson, K.C., and Mr. T. Cartlew (instructed by Messrs. Le Brasseur and Oakley) appeared for Dr. Fisher.

The Court heard both counsel for the appellant, but counsel for the respondent were not called upon.

The Master of the Rolls, in giving judgement for the respondent doctor, said the certificate was given and the reception order made on November 10th, 1912, and Mr. Harnett was first received into Dr. Adam's mental hospital at West Malling, being removed later to a mental hospital at Croydon, and from thence to other institutions, until 1921, when he escaped. Afterwards he commenced that action by writ dated May 31st, 1922, the pleadings being delivered by October, but there was then a delay of three years, during which nothing was done in that action, Mr. Harnett being concerned in taking proceedings against Dr. Adam and Dr. Bond for causing his return to Dr. Adam's mental hospital whilst he was out on a leave of absence order in December, 1912. More than three years after the delivery of the defence the defendant redelivered it and pleaded that the action was barred by the Statute of Limitations. By Section 3—"All actions of trespass *quare clausum fregit* . . . and upon the case . . . shall be commenced and sued within the time and limitation hereafter expressed and not after (that is to say) the said actions upon the case (other than for slander) . . . within six years next after the cause of such action or suit, and not after"; whilst Section 7—"provided nevertheless that if any person or persons that is or shall be entitled to any such action of trespass . . . actions upon the case for words, be or shall be at the time of any such cause of action given or accrued, fallen or come within the age of 21 years . . . *non compos mentis* . . . then such person or persons shall be at liberty to bring the same actions, so as they take the same within such times as are before limited after their coming to or being of full age . . . of sane memory . . . as other persons having no such impediment should have done." The plaintiff now contended that he was a person *non compos mentis* within the Statute until he regained his liberty in 1921, but the simple answer to that was that the jury had found that on November 10th, 1912, he was not a person *non compos mentis*. He was endeavouring to assert two contradictory propositions: (1) that he was of sound mind; and (2) that for the purposes of the Statute of Limitations, 1623, he was of unsound mind. It had been pointed out in the course of the argument that the fact that a person was detained under a reception order was not absolutely conclusive on the fact of insanity. It was quite different where there had been an inquisition in lunacy and the patient was found to be insane. It was said that a liberal interpretation should be given to the proviso, so that it should enure to the benefit of the plaintiff and to the disadvantage of the defendant. He (his Lordship) felt bound to say that in many cases great hardship might be caused to the defendant if a cause of action should survive so long as the present one had done. It was, indeed, for that very reason that the Act was passed. The Act did not cut at the root and destroy the cause of action, but it barred the remedy. Section 3 was absolute, and if the relief provided by Section 7 did not cover the facts of the case the action was definitely barred by Section 3. *Non compos mentis* meant a person of unsound mind, and did not include a person wrongfully detained under a reception order as being a person of unsound mind. The appeal would be dismissed, but without costs, as the plaintiff had succeeded on the issues of sanity and the amount of damages.

Warrington and Scrutton, L.JJ., delivered judgement to the same effect.

## ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

At a meeting of the College held on July 23rd, when Dr. A. Logan Turner, president, was in the chair, the following 28 successful candidates, out of 66 entered, having passed the requisite examinations, were admitted as Fellows:

R. F. Atken, H. Battr, C. E. M. Blumer, R. R. S. Bowker, W. H. B. Bull, A. W. Davidson, G. V. Davies, H. D. Gandhi, Lieut.-Colonel W. C. Gray, I.M.S., C. W. Harrison, N. R. Houston, D. R. Jennipies, O. J. MacGillivray, J. Macle, D. R. Macle, T. Nicol, Secluna, Thompson, A. J. West, R. A. Wilson, W. A. D. Woolgar.

## Medical News.

At the meeting of the Parliamentary Medical Committee on July 28th Dr. Fremantle, who was in the chair, read a letter from the Earl of Balfour announcing that the Committee of the Privy Council had considered the petition of the Royal College of Surgeons of England praying for the grant of a Supplemental Charter, together with the counter-petition of Dr. Redmond Roche and others, the reply of the Royal College to the counter-petition, and the resolutions passed by the Parliamentary Medical Committee in support of the counter-petition. In view of the fact that the counter-petition raised highly controversial points on which there was a division of opinion within the Royal College, the Privy Council could not recommend the adoption of its proposals. The draft Supplemental Charter prayed for by the Royal College had been formally approved by the King at the Privy Council on June 26th. The Parliamentary Medical Committee decided to take no further action in the matter.

THE annual meeting of the British Association will begin at Oxford on Wednesday next, August 4th, and the President, the Prince of Wales, will deliver his address on the evening of that day. He will, it is anticipated, deal with relations between scientific research, the community, and the State, both at home and in the overseas dominions. The meeting of the sections, twelve in number, will begin on the following day and continue until Tuesday, August 10th. The concluding general meeting will be held on Wednesday, August 11th, at noon. The president of the Section of Physiology, Professor J. B. Leathes, will give his address, on function and design, on the morning of Thursday, August 5th. On Friday the section will meet jointly with the Section of Zoology to discuss the value of tissue culture in biology; the opening paper will be by Dr. H. M. Carleton, of the Department of Histology at Oxford, and among the speakers will be Professor Charles Champy, of the Sorbonne, who will give an account of his methods and the results he has obtained.

THE St. Thomas's old students' dinner will be held on October 29th at the Hotel Victoria, Northumberland Avenue, at 7.30 p.m.; Dr. R. Percy Smith will take the chair. An alphabetical and local list of old students has been prepared, and may be obtained from the medical secretary, St. Thomas's Hospital; included in this pamphlet is a list of past and present officers of the hospital and medical school.

SIR JAMES CRICHTON-BROWNE, who recently resigned the office of treasurer of the Royal Institution after holding it for thirty-seven years, was presented last week by his fellow members with a silver-gilt cup of the Empire period. The president, the Duke of Northumberland, in making the presentation, said that when Sir James took office the endowment fund of the Institution was £22,724, and of the research laboratory £62,000. The endowments at the present time were £122,500 and £88,295 respectively. In him the Institution had had the rare combination of devotion, sound judgement, unflinching tact, and the quality of inspiring friendship and confidence. Sir James Crichton-Browne, in response, predicted that the Institution's educational work would continue with increasing success and that it would promote discoveries which would help the industrial prosperity of the country.

ARRANGEMENTS have been made by the Fellowship of Medicine and Post-Graduate Medical Association with the Dean of the Brompton Hospital to permit graduates to attend the daily clinical practice of the hospital for the month of August. The fee for this privilege is payable to the Secretary of the Fellowship of Medicine, who will issue the necessary permit. The Queen's Hospital for Children, Bethnal Green, will give an all-day course from August 16th to 28th, including the medical and surgical aspect of diseases of children. From August 23rd to September 4th Queen Mary's Hospital, Stratford, has organized an all-day "brush-up" course for those desirous of renewing their acquaintance with up-to-date hospital practice. The programme will include demonstrations in general surgery, medicine, orthopaedics, and laryngo-

logy. The City of London Maternity Hospital provides courses in obstetrics and child welfare; these are held weekly and are limited to four graduates. Practical courses in anaesthetics can be arranged at any time. Full particulars of these courses can be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

THE sixth British Congress of Obstetrics and Gynaecology will be held in Manchester on April 27th, 28th, and 29th, 1927. The principal subject for discussion will be the treatment of inflammatory conditions of the uterine adnexa, and this will occupy the first day of the meeting. The remaining days will be devoted to the reading of short papers on obstetrical and gynaecological subjects and demonstrations of surgical operations. A museum of pathological specimens is also being arranged. Those intending to take part in the discussion, or to read short papers, are invited to send in their names, together with the title of any proposed contribution, not later than March 1st, 1927. The secretaries of the congress are Dr. Daniel Dougal, 11, St. John Street, and Dr. John Bride, 2, St. John Street, Manchester.

A THREE weeks' post-graduate course has been arranged at Trinity College, Dublin, from September 13th to October 2nd. It will be conducted as in former years, and will consist of clinical meetings at hospitals in the morning and laboratory classes in the medical school in the afternoon. A limited number of members will be able to reside in college rooms. A prospectus giving details of the course and cost may be obtained on application to the Honorary Secretary, School of Physic, Trinity College, Dublin.

A COURSE in practical orthopaedics will be given at Berc-Piage during the week commencing August 9th, and will deal specially with the treatment of surgical tuberculosis, infantile paralysis, and fractures. The fee for the course is 150 francs, and further information may be obtained from Dr. Fouchet, 69, Quai d'Orsay, Paris, or the Institut Calot at Berc-Piage.

THE fourteenth congress of the Spanish-American Ophthalmological Society will be held at Salamanca from September 15th to 18th, when the subjects for discussion will be: stereoscopic vision, introduced by Dr. Diaz Caneja, and dacryocystorhinostomy, introduced by Drs. Casadéus and Basterra.

THE next French congress of oto-rhino-laryngology will be held at the Paris Faculty of Medicine under the presidency of Professor Sébilleau from October 13th to 17th. Further information can be obtained from the general secretary, M. Georges Liébault, 216, Boulevard St-Germain, Paris VII.

THE German Pharmacological Society will hold its sixth annual meeting in Düsseldorf from September 22nd to 26th; the subjects to be discussed are chemotherapy and protein therapy.

SYMPATHETIC obituary notices of Sir Frederick Mott and Sir William Leishman will be found in the issue of the *Archivos de medicina, cirugía y especialidades* for June 26th.

THE KING has granted Dr. Roy M. Humphreys, Inspector of the Sudan Medical Service, licence and authority to wear the Insignia of the Fourth Class of the Order of the Nile conferred upon him by the King of Egypt for valuable services rendered.

PROFESSOR RAMÓN Y CAJAL, emeritus professor of histology at Madrid, has been elected a member of the Academy of Vienna.

THE epidemic of small-pox in Sutton-in-Ashfield cost the urban council an amount which will probably make it necessary to impose an extra rate of 1s. 3d. in the £. The expenditure of the council on the epidemic during 1925 was £2,267, and of £1,500 allowed last April to deal with small-pox £1,100 had been spent in the first quarter of the financial year. It was estimated that each patient cost £18 for isolation, etc.

THE statistics for 1925 compiled from reports of health authorities of the United States show that there were 43,193 cases of small-pox in the United States. During the first quarter of this year several thousand cases occurred in California, with 163 deaths, 136 of which were in Los Angeles alone. In Providence, on the other hand, where there has been an energetic vaccination campaign, there has been only one death from small-pox in the last fifty years.

OUT of a total of 147,010 medical practitioners in the United States 2,532 died in 1925. Their ages ranged from 25 to 107. Most of the deaths occurred between 60 and 70. Of the 2,420 deaths of which the causes were known, 879 were due to diseases of the circulatory system, including 559 of morbus cordis. Cerebral haemorrhage occupied the second place, with 233 deaths. Pneumonia was responsible for 223 deaths, and influenza for 26. Genito-urinary diseases caused 227 deaths, of which 161 were due to nephritis; 33 deaths were attributed to appendicitis, 118 to cancer, and 62 to tuberculosis. In 230 old age was the only cause assigned.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The Editor, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **British Medical Journal** alone unless the contrary be noticed to be taken of their names, not

Authors desiring REPRINTS of their articles published in the **British Medical Journal** must communicate with the Financial Secretary and Business Manager, **British Medical Association House, Tavistock Square, W.C.1.**, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager:

The TELEPHONE NUMBERS of the **British Medical Association** and the **British Medical Journal** are **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscern Westcent, London.*

The address of the Irish Office of the **British Medical Association** is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the **Scottish Office**, 6, Drumshugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

### QUERIES AND ANSWERS.

"P. S. H." asks how he can best deal with a plague of fleas between the boards in an old wing of his house. Some improvement has followed washing the floors with 1 in 1,000 mercury perchloride, but the plague is not altogether stayed.

MR. D. S. PUTTANNA, F.R.C.S.Ed. (Krishnarajendra Hospital, Mysore), asks for advice in the treatment of a girl, aged 7, who is suffering from patches of leucoderma on the face and extremities.

DR. RAWEL CHAND SURI (Suri Medical Hall, Rawalpindi) writes with reference to an inquiry published last December (vol. ii, p. 1252) to inform us that there is a vaidic medicine named *Yegraj*, which is a compound of many drugs. He offers to obtain fuller information if the inquirer desires.

### PAIN AFTER ARTIFICIAL MENOPAUSE.

"D. K. M. D." writes: Comments on the prognosis and suggestions as to the treatment of the following case would be appreciated: A single woman, aged 44, had suffered from pre-menstrual and menstrual pain since puberty. The uterus and adnexa seem normal. The uterus has been dilated and curetted on various occasions with little benefit, and the usual drugs were useless. Pain became so severe that she spent ten days in bed at each period, and on occasions required morphine. Her general health was poor. In September, 1925, she had deep x-ray treatment with a view to inducing the menopause, and has not menstruated since, but she complains of dragging pains which are more or less constant and are aggravated by exercise; they are not usually so severe as the previous menstrual pain, but as they are more or less always present, her condition has, in some respects, been worsened by treatment. She had further x-ray exposures in March last, and is at present taking liquor sedans in doses of 1 drachm.

### THE SPÄHLINGER TREATMENT.

"A. F." writes: In reference to the efforts made for several years past to induce the Ministry of Health to make a grant to enable M. Spähliger to carry on his work, is there any evidence that similar application has been made to any other Government; and, if so, with what result? Also, have the medical men of any other country shown any practical interest in the question of this treatment?

"\* \* We understand that the Swiss Government has instituted an inquiry into the value of M. Spähliger's preparations in the treatment of tuberculosis in cattle.

### INCOME TAX.

#### Income from Property.

"H. S. B. J." owns some property, the rents of which are more than swallowed up by interest payable on a bank advance and by the cost of repairs, but he is called upon to pay income tax.

"\* \* Apparently the bank interest is allowed for, but not the actual amount of the repairs. There is a percentage deduction from the gross rental value, which has presumably been made, but if that is insufficient a claim can be made for a further allowance based on the average expenditure over the five previous years. In this particular case "H. S. B. J." might usefully approach the inspector of taxes with the suggestion that, having regard to the alterations made in the premises, the further special

allowance might be based on the average expenditure incurred since that date. The expense of altering the premises is not, in the circumstances, allowable expenditure.

"W. A. N." inquires as to the assessment of untaxed interest and as to the new regulations with regard to the Irish Free State.

"\* \* Assuming that interest was received from a bank deposit and from 5 per cent. War Loan both last year and this year, the interest should be returned for assessment in each case on the basis of the amount received last year. The position with regard to the head rents from the Irish Free State may become clearer when the present proposals have become law; at the moment we are of opinion that "W. A. N." will have to allow deduction of Irish Free State tax from the rent and reclaim it by showing that he is chargeable to tax thereon in the United Kingdom.

### Purchase of Apparatus.

"D. M. M." has claimed to deduct as a professional expense the cost of a corneal microscope on the ground that it comes under the statutory rule authorizing the deduction of "sums expended . . . for the supply or repair of implements . . . employed." The inspector objects that the item in question is capital expenditure.

"\* \* We are of opinion that the inspector is correct and that the rule quoted does not refer to expenditure incurred in improving the equipment by adding an instrument of a kind which it had not previously included, but to the supply of such articles as "loose tools" in replacement of similar ones which could not profitably be repaired. "D. M. M." will realize that his argument could be pressed to the point at which the original cost of a motor car could be claimed, an argument which is clearly untenable.

### Replacement of Motor Cars.

"C. G. G." refers to the reply given to "A. M." in our issue of July 3rd and desires further explanation as to the arguments against "A. M.'s" full claim.

"\* \* It is a fundamental principle of the income tax, enforced by many judicial decisions, that no allowance can be made for loss of capital. The one exception is the allowance given for wear and tear of plant and machinery year by year, which was not in point in "A. M.'s" case. If a car costing £350 is sold for £100 and a similar one bought for £250, the net result is that the practitioner has expended £150 in replacing his car, and has lost £100 of his original capital through the fall in prices; that £100 was lost whether he bought another car or not, and as the loss was independent of the sale, it is, if allowable at all, allowable whether the sale was made or not. If, instead of buying the £250 car, the practitioner buys a superior car for £350, the foregoing still holds good; the difference is that there is another ingredient in the transaction: £100 of the original capital has been lost, but another £100 has been invested in the improvement of the equipment of the practice. On neither ground is any allowance due. Every practitioner is, of course, entitled to purchase what kind of car he wishes, but in our opinion the authorities are entitled to exclude from the expenditure (a) any loss of capital and (b) any amount spent in improving the equipment. We do not entirely follow our correspondent in his comments on the official notes, but he will no doubt appreciate the fact that they purport to deal with "any amount expended in replacing obsolete plant"; if a particular item of expenditure includes an element of improvement as well as replacement, it seems open to the authorities to point out that the note deals with replacement expenditure only.

### Motor Car Transactions.

"A. N." bought a motor cycle in 1920 for £106 10s. and sold it in 1925 for £0; he also bought an M. C. car in 1921 for £320 and sold it in March, 1926, for £65, buying an S. car for £365.

"\* \* We advise "A. N." to claim in respect of the replacement of the M. C. car, £320-£65=£255, less any depreciation allowance he may have received in respect of that car. No allowance is due for the loss on the motor cycle, as it was not replaced; if "A. N." should in the future buy and run a second vehicle (cycle or car), he might obtain an allowance against it of £35 as the belated cost of replacing the motor cycle. The claim would be an equitable one.

"F. T. B." has used an L. car for several years and has had also another car as "second string." He has had no allowance for depreciation of either of his two present cars.

"\* \* It is now too late to claim any depreciation allowance for 1925-26, but it can be done for 1926-27. The allowance will be at 15 per cent., but on the value of the cars as written down at that rate year by year to, say, December 31st, 1925; consequently it will be small as compared with the original cost of the cars. Seeing that only small allowances will have been received when these cars are replaced, we advise our correspondent to

claim obsolescence allowance when that occurs in each case; that allowance should be calculated in the same way as a replacement allowance, except that the amount of the depreciation allowance actually received for the car replaced should be added to the amount received for it when calculating the claim.

## LETTERS, NOTES, ETC.

## HYDATID CYST OF THE ORBIT.

MR. H. B. WILLOUGHBY SMITH, F.R.C.S. (Gainsborough), writes as follows with reference to the case of hydatid cyst of the orbit reported by Dr. E. A. Seale in our issue of May 29th (p. 900): "I published an account of a case of hydatid in the orbit in a native child in the *Transvaal Medical Journal*, 1906. I forget the age of the child, but the cyst was tense, and on microscopical examination of its walls, etc., hooklets were found."

## TUNGSTEN ARC LAMP IN PULMONARY TUBERCULOSIS.

DR. T. E. LARKINS (London) wishes to know whether others have had good results in the treatment of pulmonary tuberculosis by the tungsten arc lamp. His experience, after three months, is that, with only one exposure a week, the cough lessens, the expectoration dries up, and the patients say that their general health has improved. Clinically, the physical signs are better, and bacteriologically there is a rapid decrease in the number of tubercle bacilli in the sputum.

## ESERINE IN GLAUCOMA.

WE have received from the medical officer of Thar Parka Civil Hospital, Mirpurkhas, Sind, India (B. C. Vachhrajani), a note in which he relates some cases which, in his opinion, indicate that eserine is a most valuable drug in the treatment of glaucoma and should be given a good trial before operation. A solution of eserine of the strength of 4 grains to 1 ounce is used, as a rule, two or three times a day.

## POISONING BY TOBACCO APPLIED TO THE SKIN.

WITH reference to notes published recently on poisoning by tobacco applied to the skin, Dr. M. CARNEGIE SIMPSON (R.M.O., Ross and Cromarty Joint Hospital) sends the following extract from Bate's *Dispensary* (1699): "Oyl of Tobacco.—Anoint the pit of the stomach with gr. v or vi and the patient will presently vomit, but if you would move the body downwards, anoint about the navel therewith and the sick will presently fall a purging."

## DEVIATION OF THE NASAL SEPTUM.

DR. F. DALY (Shirebrook, near Mansfield) writes to express the opinion that deviation of the nasal septum (to the left in left occipito-anterior and to the right in right occipito-anterior) is brought about at birth by the pressure of the maternal parts in the soft yielding bones and cartilage of the child's nose. Firm pressure with finger and thumb on the nasal septum, just above the alae nasae, with traction in a downward and outward direction, corrects the deformity during the first two or three weeks of life.

## MENTAL IRRITABILITY AND BREAKDOWN IN THE TROPICS.

DR. OSWALD HORROCKS, F.R.C.S.Ed. (C.M.O. Annamalais Medical Association, Valparai, South India), in a letter on this subject, writes: "I have read the several letters in the *JOURNAL* during the past three weeks on the above subject. As it is necessary that a thorough investigation should be made and the real causes found, may I help by the following opinion, formed during the last three years I have been resident in Southern India? I believe that a deficiency of thyroid is at the bottom of the whole trouble. The gland may not function owing to hereditary tendencies. All the causes enumerated in other letters—such as bad food, the glare of the sun, drink, isolation, quinine, etc.—may affect a young man, but in spite of all these conditions his friends tell him that he is putting on fat. He is really becoming myxoedematous, with all its terrible symptoms of lassitude, etc. To help himself he drenches his system with salines, which make him worse; he finds temporary relief in drink, eventually taking too much.

The exciting causes in Southern India are high temperatures of disease lasting for some time, as in neglected malaria, typhoid fever, and suppurations—for example, appendix abscess and puerperal fever. I have had patients between the ages of 19 and 70 markedly improved on the administration of thyroid gland tablets.

A lad aged 19 (son of a myxoedematous mother), who had had malaria badly, and suppurated after a motor-bicycle accident, consulted me for lassitude, disinclination for his work, irritability of temper, sudden annoying attacks of frothy diarrhoea, and threatening suicide if he lost his job. I started him on 2-grain doses of thyroid nightly, telling him to increase the dose by half a grain until he found the amount that practically made him well. He is now taking 5 grains and is in perfect health and happy. His diarrhoea was probably the beginning of sprue. He takes no drink. Stop his thyroid for a week and he is ill once more. His mother had suffered from malaria badly before the birth of her son, and put on 4 st. in weight immediately after; she described it as "flabby fat," as if she were a beer drinker. She has not been the same as before. Her heart could not stand any strain: a sudden noise would upset her; looking down from a moderate height made her giddy and feel inclined to throw herself over. There was fear of impending death in a train or

motor car, a terrible feeling of lassitude described as a sinking through the earth. Her temper was becoming unbearable; she was a misery to herself and all around. Three years ago she consulted me for terrible acidity, with severe vomiting and collapse: 4 grains of thyroid at night and 2 grains after lunch keeps her in good health. She has lost all her symptoms; her heart has improved to such an extent that she enjoys a walk and plays badminton. Her memory, which she was rapidly losing, is now quite normal.

I believe a healthy man from home with a little care can live in any part of the world. A small proportion of drinkers abroad take alcohol for amusement's sake, but the greater number have something wrong and take it for the relief of lassitude and other symptoms. What makes the drink worse is the quantity of aerated soft water used to dilute the alcohol. It acts on the sweat glands and kidneys and reduces the salts in the blood. I have often seen six pints of fluid consumed by one man in an hour.

DR. E. HOBHOUSE, in the course of a note on this subject, writes: "There are few more obscure problems in medicine than the interaction between the animal organism and its physical environment, climatic and meteorological, quite apart from the difficulty of excluding social and individual factors. I lived for two years in Colorado, at elevations of 5,500 ft. and over. It was well recognized that after a continuous stay many people, especially women, became restless, sleepless, and irritable. But the first effect was that exaltation which the Bishop of Singapore mentions, as described by Dr. Leys in Kenya, and which frequently led to overexertion on the first arrival. A brief return to lower levels every year was sufficient to put most people right; if they stayed on the depressed, but I never heard of any! as the result. The majority of the energetic life under a sun which shone as long and as brightly as in almost any quarter of the globe. But the state of mental instability, which may end in suicide, is wholly different from that produced by the exciting effect of the high altitude climate which may lead to acts of violence, and it is impossible to suppose that both are due to the effects of sunlight alone. Other factors come in of which, I believe, the chief is humidity. In fact, the effect of the solar rays is quite different in Colorado and inland Australia, outside the tropics, both dry regions. Sunstroke, so called, in Colorado is practically unknown, even though summer temperatures of 90° F. and over are common. Both there and in Australia it is possible to ride or work in the open all day with the thermometer standing at from 90° to 110°, without any more protection than in England. I understand this is also true in Kenya and elsewhere, though I believe it would be considered lunacy to attempt the same in India or the Malay Peninsula. At present, so far as I know, there is no sufficient scientific reason to be alleged for these differences, and the whole subject requires much more careful investigation considering its importance to the empire. The problem, for example, of how much of Australia is really a "white man's country" depends on these factors."

## A HUMAN OSTRICH.

DR. J. LIVINGSTON (Barrow) sends a description of the removal by operation of a large number of foreign objects swallowed by a patient—a man, aged 35, who was admitted to hospital with acute peritonitis, the provisional diagnosis of appendicitis having been made. Knowing the patient's previous history, he was questioned as to the possibility of his having taken anything to cause his illness. He denied this and was apparently quite rational. On opening the abdomen the whole peritoneum was seen to be intensely inflamed, and several very hard foreign bodies were felt in the intestinal canal near the ileo-caecal valve. The foreign bodies were: two slate pencils  $\frac{1}{2}$  in. and  $\frac{1}{4}$  in. long; part of an iron boot-heel plate, 3 in. by  $\frac{1}{2}$  in.; a thin iron plate, 1 in. by  $\frac{1}{2}$  in.; a piece of lead piping,  $\frac{1}{4}$  in. by  $\frac{1}{2}$  in.; the blade of a knife,  $\frac{2}{3}$  in. long; two needles,  $\frac{3}{4}$  in. and  $\frac{1}{2}$  in. respectively; half a safety-pin,  $\frac{1}{2}$  in.; three nails,  $\frac{1}{2}$  in. long; a piece of metal,  $\frac{1}{2}$  in. by  $\frac{1}{4}$  in.; and a piece of glass,  $\frac{1}{4}$  in. by  $\frac{1}{2}$  in. The sharp edge of the larger iron plate had perforated the bowel in several places during its passage. The long objects and the piece of glass were found collected in the second part of the duodenum, and were removed with difficulty. The patient died two days later, and at the necropsy another small needle was removed from the pancreas and a collapsible tube,  $\frac{1}{4}$  in. long, from the intestinal tract.

## LONGEVITY IN A FAMILY.

DR. A. E. ROCHE (London, W.) writes: "Having received from a paternal uncle (one of a family of nine, all surviving, well, and active) a list of the ages of his brothers and sisters, I think it of sufficient interest to justify publication. The three eldest are males aged 79, 77, and 75, and a female follows aged 74. Next come two males aged 70 and 69, after whom there are three females, whose ages are 67, 64, and 63. The average age of the nine is thus 70. Echoing the query so frequently met with in popular publications, I ask, 'Can any reader beat this?'"

## VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 31, 32, 33, 36, and 37 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 34 and 35.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 102.

## British Medical Association.

## PROCEEDINGS OF SECTIONS AT THE ANNUAL MEETING, NOTTINGHAM, 1926.

## SECTION OF OBSTETRICS AND GYNAECOLOGY.

COMYNS BERKELEY, M.D., M.Chir., F.R.C.P., President.

## PRESIDENT'S OPENING REMARKS.

THE President, in his opening remarks, reminded those present that it had always been the tradition of that Section, at any rate, to select as subjects for discussion those which interested more especially the general practitioner. The committee, in accordance with this tradition, had selected three subjects for this meeting, and it could truly be said in connexion with all three that the family doctor was frequently being called upon to give advice and, in many instances, to make important decisions. The subject of that morning's discussion, the indications and methods for the termination of pregnancy before the viability of the child, was one which members of the medical profession were continually coming up against, and often being worried about, and he was sure that all present were looking forward to a most interesting discussion.

## DISCUSSION ON INDICATIONS AND METHODS FOR TERMINATION OF PREGNANCY BEFORE THE VIABILITY OF THE CHILD.

## OPENING PAPERS.

I.—THOMAS WATTS EDEN, M.D.,

Consulting Obstetric Physician, Charing Cross Hospital.

## THE INDICATIONS FOR INDUCTION OF ABORTION.

## GENERAL CONSIDERATIONS.

THE medical profession has always recognized that its members should not make themselves responsible for the termination of pregnancy unless there are good reasons for believing that completion of the pregnancy would actually endanger the mother's life or prejudice her future health. It has never been possible, and probably never will be possible, to lay down strict rules as to the conditions under which abortion may be or should be induced. If it were possible, these rules would need revision from time to time, to bring them into line with progress in the management of disease. It is therefore a matter of practical interest for us to take stock of the position from time to time, and see to what extent we are agreed upon the conditions which may fairly be regarded as indications for inducing abortion.

I am not one of those who feel that our attitude should be a very rigid one in this matter. Each case deserves consideration on its merits, and sympathetic consideration too, for although to a healthy woman pregnancy is often a period of unusual well-being, to an ailing woman it may be a long-drawn and painful penance. We ought to make it clear to our patients that this aspect of the matter has been duly weighed in the advice we give them.

It is an ethical question of great interest to what extent we as doctors have the right to insist that a woman shall pass through an ordeal which she is unwilling to face, even if we do not think that she will sustain any permanent injury from so doing. I recollect a case that occurred many years ago now, which first led me to relax the rather rigid views in which I had been brought up. I had attended the wife of a distinguished barrister in her first and second confinements. A third pregnancy followed after rather a short interval, and she was very unwilling to go on with it. She was a woman of great intelligence and of a sensitive artistic temperament. Both she and her husband took the view that, the prospective baby being theirs, it was their own

affair whether they allowed their work to be completed or not. They did not care a jot for the rigid views generally taken by the medical profession. They had formed the opinion that a third pregnancy coming so soon would materially affect the wife's health, and they did not see why this risk should have to be faced at the dictation of professional standards. I was a good deal shaken by this view, and persuaded the patient to take the opinion of the late Dr. Herman, a man of much longer experience than I had at that time. A good deal to my surprise, he at once took the side of the patient and her husband. He agreed that their apprehensions were probably exaggerated, but he said we had no right to ignore them, and, after all, it was accepted that rapidly recurring pregnancies often affected the mother's health very unfavourably. So the end of it was that the pregnancy was terminated. The sequel to the case Dr. Herman never knew. Within six months the same thing happened again—that is, the patient became pregnant and wanted it terminated. This time I flatly refused to interfere, with the consequence that they went to one of my colleagues, whom they found more pliable, and I have never seen them since.

I am, however, prepared to defend the view that it may at times be right to terminate pregnancy, even if the mother is not suffering from any condition which could, strictly speaking, be called disease. The cases in which this can be done require, however, the most careful consideration, and the propriety of interfering in such circumstances must be held with a tight rein.

As a rule when we advise the induction of abortion it is for some definite morbid condition which can be classed as disease. I do not propose to weary you by going over all the conditions which can possibly be said to be indications; you will find them all in the textbooks. It will be more congenial to the atmosphere of a summer meeting if I take up a few of the more important ones, which we may all expect to meet with in our ordinary work.

## MEDICAL INDICATIONS.

## PHthisis.

I will first take the subject of pulmonary tuberculosis. You will not be surprised to hear that obstetricians differ as to the necessity of terminating pregnancy in this condition—not only English obstetricians, but those of other countries also. It is not a question for the obstetricians alone, for the views of physicians with large experience of the treatment of phthisis must also be taken into account. The teaching of Osler<sup>1</sup> may be summarized as follows:

1. A woman with arrested or cured pulmonary phthisis, where the family history is bad and her physique below the standard, runs grave risks if she becomes pregnant; if, however, there is no hereditary taint and her physique is good, there is not much risk.
2. If there is active disease—that is, fever, bacilli, etc.—pregnancy usually hastens the process, and the disease advances rapidly after parturition.
3. The risk increases greatly with repeated pregnancies. Osler quotes with approval the dictum of Dubois: "A woman threatened by phthisis may bear the first accouchement well, the second with difficulty, the third never."

In my opinion this is a matter in which we, as obstetricians, should act only in close association with our medical colleagues. We are not, in point of fact, in a position to decide for ourselves. There are a number of points at which midwifery and medicine come into close contact, and these points must be viewed from both sides in order that their bearings may be properly understood. For my own part I am prepared to accept and act upon the views of Osler which I have just quoted. This means that we should be prepared to terminate pregnancy in the early months whenever there is active pulmonary phthisis, except in the case of patients who are obviously dying. And further, that in cases of healed or arrested phthisis the whole circumstances should be reviewed in consultation with a physician before coming to any decision. It will be remembered that we are not considering the question of inducing labour with a viable child; that is another story into which I must not enter.

A word or two on the chances of life of children born to a phthisical mother will not be inappropriate. The statement is usually made that phthisical mothers bear well

developed and healthy children. As a matter of fact they usually do, although we know that tubercle bacilli can pass through the placental filter. There is some reason to believe, however, that apart from the transmission of tubercle the expectation of life of these infants is not normal. The statement is made by Couvelaire<sup>2</sup> that of infants born of mothers with active phthisis (tubercle bacilli in sputum) 38 per cent. do not survive the first month of life; this compares with an average mortality in France for the first month of 4.15 per cent. Couvelaire attributes this, not to direct transmission of the disease, but to the fact that these infants are born with a "diminished coefficient of vitality." I know of no corresponding observations in this country for the first month of life, but some very valuable data on the condition of the children of tuberculous mothers have been published recently by Dr. Ward, the tuberculosis officer for South Devon.<sup>3</sup> Dr. Ward traced the history of 372 of these children born in his district, and found that 34 per cent. became definitely tuberculous and a further 21 per cent. were suspect; of those definitely tuberculous one-fourth died. He concludes from control observations that the children of a tuberculous mother are seven times more likely to become tuberculous than are those of healthy mothers. Dr. Ward's observations led him to the further conclusion that of tuberculous women who became pregnant over 50 per cent. were definitely worse, while 19 per cent. were definitely improved. In addition to the 50 per cent. who became worse, in a further 21 per cent. the disease began during either pregnancy or the puerperium.

There seems no escape from the conclusion that on the whole pregnancy is a definite risk to the tuberculous mother; and further, it is not to the advantage of the community that children should be born over whom there hangs a risk of tuberculosis seven times greater than that which is run by other children. To my mind these considerations form very powerful arguments for the termination of pregnancy in women who are subjects of active tuberculous disease.

#### *Chronic Nephritis.*

To women suffering from chronic nephritis pregnancy is always attended by certain very definite risks. In the first place, complete breakdown of the renal function may occur during pregnancy, leading up to uraemic convulsions; in the second place, an intercurrent attack of acute nephritis may supervene during pregnancy; in the third place, supposing these complications occur and are survived, the working capacity of the damaged organs will be permanently reduced. Further, accidental haemorrhage, especially the toxæmic form which is associated with interstitial haemorrhage and necrosis of the uterine muscle, occurs in a relatively high proportion of cases of chronic nephritis. Lastly, in addition to the maternal risks the foetal risks are very heavy: probably not more than 60 per cent. of the children survive, death being due partly to prematurity and partly to the results of transplacental intoxication.

Notwithstanding these clearly defined risks, it is possible for a woman with chronic nephritis to survive the ordeal of repeated pregnancy, and to produce a fair proportion of children who survive. Herbert French, in his Goulstonian Lectures,<sup>4</sup> mentions the case of a woman who had shown the signs of chronic nephritis for thirteen years, and who bore six children, but he does not state how many of them survived. It is necessary, therefore, to take a reasoned view and to realize that the conditions I have mentioned are, after all, risks and not certainties. A proportion of cases will always escape, and the time may come when we can distinguish, more clearly than at present, the factors which render prognosis grave from those which render it more favourable.

The clinical type of nephritis has an important bearing on the prognosis. The hydraemic type, which is characterized clinically by dropsy, and in which the renal difficulty is in the passage of salt and water, is much more serious from our present point of view than the azotaemic type, in which there is no dropsy, but slowly progressive cardio-vascular and retinal changes, and in which the renal difficulty is in the excretion of the waste products

of metabolism. In cases of the latter class pregnancy may be expected to proceed much more favourably than in the former.

We might, perhaps, put it like this: that a pregnant woman with chronic nephritis who develops dropsy in the early months, especially if this affects the face and upper extremities, is in great danger. In the absence of the early appearance of dropsy the danger is not so obvious at the moment, but if pregnancy is allowed to continue a most careful watch should be kept upon two things: (1) the adequacy of renal elimination as shown by a combination of the blood urea estimation with the urea concentration test in the manner advised by Professor Hugh Maclean, (2) the blood pressure.

I suggest that the following considerations may guide us in regard to the question of inducing abortion: (1) A woman with chronic interstitial nephritis (azotaemic type) may be allowed to carry on under supervision with her first pregnancy. (2) In subsequent pregnancies early abortion should be induced if a serious renal breakdown—for example, uraemic manifestations—occurred in the previous pregnancy. (3) In any woman with chronic nephritis the occurrence in early pregnancy of albuminuria, and oedema of the renal type, justifies, if it does not actually require, the induction of abortion.

#### *Bacillus coli Infection of the Urinary Tract.*

This condition in its subacute form, which is not uncommon, does not lead to serious developments during pregnancy, although it is sometimes the cause of an acute outbreak of fever during the early puerperium which may closely resemble the onset of puerperal sepsis. I have, however, seen a case, early in the present year, in which abortion had to be induced, and the circumstances were so uncommon that it may be of interest to give them in brief outline.

The patient was a young lady about six and a half months advanced in pregnancy when I saw her in consultation. Earlier in her pregnancy she had had a very acute urinary infection which led to the formation of an abscess in the left kidney; this kidney was removed; she survived the operation without interruption of the pregnancy, and her general condition improved very greatly. All went well for six or seven weeks, and then fever reappeared, with acute pain in the right renal region, and the urinary signs of a *Bacillus coli* pyelitis. The patient had only one kidney; it was imperatively necessary to safeguard this kidney from further damage, and in view of the results of the first attack it was decided to terminate the pregnancy at once, which was done by Caesarean section, as the indications for intervention were urgent.

This case is, of course, quite exceptional, and I quote it only to show that a condition which as a rule is comparatively free from risk may nevertheless develop in such a manner as to threaten life.

#### *Diabetes Mellitus.*

I need say very little about this condition because, although in the past we have regarded it as one of the gravest intercurrent diseases in pregnancy, with the resources of insulin treatment at our disposal its risks have been very greatly reduced, though not, I believe, entirely eliminated.

May I remind you that the detection of sugar in the urine is not enough of itself to establish a diagnosis of diabetes? Glycosuria and lactosuria are not uncommon in pregnancy; they are not accompanied by an increase in the percentage of blood sugar, nor are they accompanied by the characteristic symptoms of diabetes, such as polyuria, thirst, and wasting. Glycosuria is apparently due in these circumstances to a lowering of the renal threshold for sugar, and I believe it is at present an unsettled question whether or not there is a risk in such cases of the subsequent development of a true pancreatic diabetes. A case of simple glycosuria is always amenable to dietetic treatment, and never forms an indication for abortion.

#### *Heart Disease.*

Valvular disease of the heart seldom calls for induction of abortion. A young woman with a well compensated valvular lesion will, as a rule, pass through one, or possibly two, pregnancies without suffering serious inconvenience. Repeated pregnancies, especially if they follow quickly upon one another, undoubtedly damage the heart and reduce the patient's expectation of life.

The nature of the valvular lesion is of little importance; it is the state of the cardiac muscle which controls the situation, and it is only when signs of failure occur that the condition becomes serious. In my opinion there are two types of case in which it may be right to induce abortion: (1) the woman who in the early months of pregnancy shows signs of failure of compensation; (2) the woman in whom a previous pregnancy led to a serious cardiac breakdown. In the latter instance pregnancy should be terminated at the earliest possible moment, for there is no doubt the patient is in imminent danger. In the former the risk is less serious, and by careful management she may come through successfully. The risks should, however, be explained to the patient, and if it is her own wish to face them our duty is to do all we can to minimize the danger.

#### *Diseases of the Nervous System.*

*Insanity.*—I have several times terminated pregnancy on the advice of a psychiatric physician in one of the following set of circumstances: (1) the patient had recovered from a previous attack of puerperal insanity; (2) the patient was what is called a "border-line" case, and had a bad family history. I regard such cases as these as pre-eminently suitable for team work. I do not think general practitioners or obstetric surgeons should, either alone or together, assume the responsibility for a decision. The whole of the circumstances of the case should be reviewed by the general practitioner, the psychiatric physician, and the obstetric surgeon in company, and considered in all their aspects before induction is decided upon.

*Chorea* is a disorder which is not very uncommon in pregnancy, and which is, as a rule, amenable to simple management by complete rest in bed (in a room apart), careful feeding, and the administration of arsenic. Occasionally severe cases associated with pyrexia are encountered; these are often obdurate, and it may be that termination of pregnancy may now and then be necessary in the pyrexial cases. In all others, no matter how severe the clonic spasm may be, induction of abortion need not be considered.

#### *Psychopathic Disturbances.*

I have made use of this heading to bring in a case which I do not know how to classify otherwise. The details of the case are briefly as follows:

The patient was a young woman who had had two children; after her second confinement an operation for suspension of the uterus was done (in 1919), which was followed by a very severe and prolonged phlebitis of the left leg, affecting chiefly the thigh. For many months she was in bed, and the leg never completely recovered. During her convalescence she was seen twice by an obstetric surgeon, now deceased, for whose opinion I always held the highest regard. He formed the opinion, and impressed it seriously, not only upon the patient, but also upon her husband and her mother, that it would be most dangerous for her to have another child at any time. When, therefore, at the beginning of the present year, she realized that she had again become pregnant, she, her mother, and her husband were all convinced that her life would be endangered if pregnancy was allowed to continue. I saw her in consultation with her family doctor and another obstetric surgeon, and each one of us was impressed with the seriousness of the effect produced upon the minds of all three of them by the opinion given at the time of her serious illness. The patient's mental condition was pitiable; she was, colloquially speaking, "scared to death," and nothing that any of us could say, although we said it repeatedly for several days while she was under our observation, produced the slightest change in her mental attitude. Her general health was fairly good, her pregnancy was normal, and there was nothing in the pelvis to suggest that any inflammatory residue had been left in the broad ligaments. The left thigh was a bare half-inch larger in girth than the right, but there was no other physical change in the limb. Two points were clear to us: (1) she would have been perfectly willing to continue if she had not been convinced in her own mind that she would never get over it; (2) there was absolutely no reason for intervention apart from her mental condition. What, then, were we to do? The patient, her mother, and her husband believed her life to be in danger; her own attitude was, "It is all very well for these men to say there is no danger, but if they are wrong I shall die, as the other doctor said I should."

We were powerless to get this attitude modified; we therefore decided to terminate the pregnancy, and this was successfully carried out.

If any are disposed to think that we acted wrongly I would ask them to consider what effect six months of mental torment would produce upon both the mother and

the child she was carrying. The effect of fear depends in no way upon the extent to which fear may be justified, and when we cannot eradicate it we must give it due weight in our considerations.

I hope I shall not hereafter be quoted as holding the opinion that any woman who says she is afraid of having a baby may be relieved of it. The circumstances of the above case are, in my experience, unique, and if there is a moral to the story it is this—that it can seldom, if ever, be our duty to tell a patient that it would be impossible for her to survive another pregnancy.

#### OBSTETRIC INDICATIONS.

These are, comparatively speaking, few and relatively unimportant. I propose to speak of three only—namely, toxæmic vomiting, vesicular mole, and retention of a dead ovum.

#### *Toxæmic Vomiting.*

Under this heading I include only that form of persistent vomiting in early pregnancy which is accompanied by definite signs of toxæmia, such as a heavy albuminuria, a raised blood pressure, pyrexia, and wasting. Toxæmic vomiting sometimes proves to be incurable by medical means, and must then be arrested by terminating the pregnancy. Cases which come to induction are extremely rare in London, and I have not myself for many years seen a case which I thought required it.

It is difficult to form any estimate of the frequency of toxæmic vomiting. In the year 1913 the Registrar-General's report shows that 42 deaths were certified in England and Wales as being due to "uncontrollable vomiting" out of 3,500 deaths from causes connected with childbirth. In the City of Manchester Lying-in Hospital 9 deaths from the condition were recorded in the ten years 1913 to 1922. Cases of vomiting which end fatally must be presumed to be toxæmic in character, and these figures indicate that, though rare, the condition is not so uncommon as some of our teachers would have us believe.

Although toxæmic vomiting is rare, other forms of hyperemesis are fairly common, and are always amenable to medical treatment. The commonest form is the functional case which can be cured by segregation, or simply by removal from home surroundings to the healthier moral atmosphere of a hospital ward. Induction of abortion is not to be contemplated in these cases, which can be distinguished by the absence of the signs which I have just mentioned as characteristic of toxæmic vomiting.

#### *Vesicular Mole.*

This condition, when diagnosed, is an invariable indication for induction of abortion. Exact diagnosis cannot, as a rule, be made until, after considerable hæmorrhage, the os internum is found to be open and the finger can detect the vesicular contents of the uterus. Before this stage is reached a presumptive diagnosis can be made from the syndrome which is fairly characteristic—namely, hæmorrhage, usually slight and continuous, overenlargement of the uterus, absence of the physical signs which indicate a foetus in the uterine cavity, and a characteristic semi-solid consistence of the uterus. If all these signs are present, the case is either one of vesicular mole or of a dead ovum with retained hæmorrhage. The treatment in either case is induction of abortion, and, as Dr. Barris will no doubt tell you, the circumstances are eminently suitable for the castor oil and quinine method of induction.

#### *Missed Abortion.*

The retention of a dead early ovum in the uterus is as a rule easily diagnosed, when an interval has elapsed which is sufficient to allow of shrinkage of the uterus. I can see no reason for leaving a dead ovum in the uterus; it is true that sooner or later it will be spontaneously expelled, and it very rarely becomes infected. It is, however, a source of annoyance and suspense to the patient, and on general principles a foreign body should not be allowed to occupy a visceral cavity when once its presence has been diagnosed. Here also the castor oil and quinine method is usually effectual.

*Haemorrhage.*

It would not be appropriate to our subject for me to say much about uterine haemorrhage. According to our classification bleeding without signs of uterine action constitutes a "threatened abortion," which is not quite what we are discussing. When, however, in a threatened abortion, active treatment is resorted to, this is hardly distinguishable from induction.

I should like to say this—that my experience is that very free haemorrhage in the early months of pregnancy does not, in all cases, result in abortion. I recollect the wife of a colleague of mine having a really alarming bleeding at two and a half months, so severe that I did not think it possible that the ovum could have survived it. My colleague, who was a general physician, was unwilling that active treatment should be resorted to, and in the event he was justified, for the child was carried to term and she is now herself a mother. I think, therefore, that we should never be in a hurry to interfere with a threatened abortion because it is attended at the onset by severe bleeding. Persistence of bleeding is of more serious import for the life of the ovum than an initial smart haemorrhage.

## II.—A. LOUISE McILROY, M.D., B.Ch., D.Sc.,

Professor of Obstetrics (School of Medicine for Women),  
University of London.

DR. EDEN has given us what we expected of him—a moderate and well balanced opinion on the indications for the induction of therapeutic abortion. He epitomizes to a great extent the opinion of a large majority of the medical profession.

The subject is of very great interest owing to the diversity of opinions held by practitioners of different nationalities. It has many difficulties, as it is easy to generalize and take a definite line of conduct in a debate; but when faced with an actual patient whose many interests come under consideration no hard and fast rule can be adhered to. Each individual case must be judged on its own merits, and the rule that applies to medical treatment in general must be applied here—namely, that the patient must be treated, and not the disease.

It may be taken as understood that every practitioner, for ethical reasons, is unwilling to perform the operation of induction and is only driven to it by dire necessity. It is a confession of failure and shows the limitations of our knowledge with regard to the treatment of disease. There is no doubt that as scientific research advances the indications for induction of therapeutic abortion will in time diminish almost to vanishing point. Everything depends upon the severity of the condition, the result, and more especially the failure, of treatment. The surroundings of the patient, the facilities for efficient treatment, all must be borne in mind and due consideration given to the conditions which would enable her to endure, or prevent her enduring, a pregnancy without risk to her health or life.

Each case must be given consideration, and the onus of advising intervention should be undertaken by the obstetrician only after consultation with a physician or, possibly, a clinical pathologist. Induction of abortion should not be a substitute for efficient treatment otherwise. Too frequently patients are sent to the obstetrician for the performance of the operation before other methods of treatment have been given a fair chance.

In this discussion I have adopted an arrangement that is somewhat different from that of Dr. Eden in that I do not include under the present classification those cases of induction in which the ovum is already dead—namely, vesicular mole, haemorrhage from separation of the ovum or placenta, and missed abortion. They do not present the same controversy, nor do they involve the same ethical aspects as are found in the case of the living ovum.

Dr. Eden says we must revise our ideas as to induction from time to time so as to keep abreast with the advances

of modern medicine which are constantly presenting new methods of successful treatment in other directions. We are now beginning to recognize that the ovum is only a temporary lodger and that its advent has not always the disastrous or malignant effect upon the maternal organism our medical forefathers were wont to believe. In my own experience, as the years go on I tend more and more to reduce the number of cases of induction of abortion, in the light of a wider knowledge concerning the conditions of pregnancy.

There are three aspects of the question to be considered—the legal, the ethical, and the therapeutic.

The legal aspect is that induction of abortion is always against the interest of the State, therefore legislative measures and precautions have been taken to prevent its performance except in cases of medical necessity. It is a criminal offence. The practitioner should make sure of his ground when confronted with a patient who is desirous of obtaining an interruption of her pregnancy. In all cases whenever possible he should secure a second opinion. In the experience of most of us women have sought our advice and tried to convince us that the pregnancy might result in suicide or great mental strain and possibly mental breakdown. While every sympathy is given to the case which Dr. Eden quotes, that of a married woman, I would like to be able to extend the same attitude of mind to a woman who comes to us distracted because of the occurrence of pregnancy after rape by an unknown assailant. It is just in such cases that complications with regard to the legal aspect of the case arise.

In my practice I have always had conscientious scruples against the performance of induction of abortion, and I teach my students the value of serious consideration before undertaking the operation. No social or economic interests apart from the medical needs of the case should be taken into account. We should not be influenced by any likelihood of defect in the character of the offspring. If completion of gestation is undesirable for medical reasons, we should urge the avoidance of subsequent pregnancies, and the necessity for abortion at future dates would therefore be eliminated. If this course is impossible, the question of sterilizing the patient has to be discussed, and in some cases sterilization is the only course to be adopted. We must not be influenced by the consideration that if we do not perform the operation of induction the next consultant will.

Advanced knowledge has led to treatment of retroversion of the gravid uterus, for example, which is in accordance with ethical teaching—and there is no doubt that a course which is attended with some difficulties to-day will be the recognized method to-morrow. Our present knowledge is limited, and we have perforce to perform induction of labour in a few cases however reluctant we may be to resort to the expedient.

The medical aspect of induction divides itself into two headings—namely, (1) induction for disease complicated by pregnancy, and (2) induction for disease due to pregnancy.

1. *Induction for Disease Complicated by Pregnancy.*

In such cases we must remember that the ovum is of the nature of a parasite to this extent—that it will look after its own interests before that of its mother. During gestation extra strain is thrown upon the maternal excretory organs, more especially in cases of defective renal function and in heart disease. We have to consider, not only the immediate condition, but the effect of pressure and increased strain in late pregnancy.

I am glad Dr. Eden took up the question of pulmonary tuberculosis first, as in my opinion it is now one of the few conditions in which induction is indicated. Acting in consultation with a chest specialist, and provided no alternative treatment is prescribed by him or is available, completion of pregnancy being likely to interfere with cure, one would certainly adopt it.

In my experience the occurrence of pregnancy is a calamity in active phthisis, especially in hospital practice. The well-being is often fictitious, especially in multiparae. The course of the disease—due to a virulent organism—is often rapid after delivery, as resistance is low, and the end may be fatal. Induction should be performed before

the twentieth week. Pregnancy should be avoided in active pulmonary tuberculosis. The pregnancy should, however, be allowed to continue in cases where the disease is arrested and facilities for treatment are available. The provision of continuous sanatorium treatment throughout pregnancy and after would do much to lessen the necessity for induction. Again, before sending patients to the obstetrician the physician ought to try all possible methods of direct treatment for the pulmonary condition—as, for instance, artificial pneumothorax.

Induction is useless if the disease is far advanced or of rapid course, as it is unnecessary to sacrifice the child. It is employed, not as a method of cure in itself, but a preventive of further advance of the disease. In my experience the infants are born healthy, but their standard of survival is lower than normal.

**Heart Disease.**—The obstetrician is frequently influenced by the physician to induce abortion, as the latter looks upon pregnancy as a disaster and labour an ordeal. I have modified my opinion regarding the serious effect of pregnancy upon heart disease; given sufficient rest during pregnancy the results are very satisfactory in most cases. The day of hurried delivery by forceps is past. In many cases the heart condition is little affected, and in some cases it is improved. In working women pregnancy is sometimes a safeguard, as it brings them under the care of a practitioner, and ensures rest and treatment. If signs of failure in compensation in early pregnancy appear, and medical treatment has failed, then the question of induction should be considered, especially in the case of a multipara. It is important to remove the element of fear from the patient. The interruption of pregnancy sometimes causes depression, and has a bad effect upon the heart. Caesarean section may be necessary if labour appears to be complicated. Sterilization of the patient is performed sometimes, but it is not always advisable, as the heart condition may so improve as to permit of pregnancy in a few years' time.

**Nephritis.**—If there is evidence of kidney damage induction may have to be performed, especially in multiparae. It is not uncommon, however, to have spontaneous abortion of the ovum. The continuance of foetal life in cases of severe nephritis is very uncertain.

**Pylitis.**—The treatment is so successful in most cases that induction of early pregnancy is seldom required. Spontaneous expulsion of the ovum may occur if the temperature is high. Induction is risky owing to the possibility of auto-infection.

## 2. Diseases due to Pregnancy.

Toxaemia is very rare in early pregnancy. Most cases of vomiting are functional; if vomiting is due to toxaemia it is a very serious condition and induction should be performed.

Hydræmiosis occurs, but is rare in the early months. Insanity may be due to toxæmia and should have appropriate treatment; it is rarely necessary to interrupt pregnancy for this disease.

In chorea abortion is rarely indicated; appropriate treatment gives better results.

In the Obstetrical and Gynaecological Unit of the Royal Free Hospital, out of 5,000 in-patients under treatment induction of abortion was performed 15 times. Of 29 cases of pulmonary tuberculosis, abortion was induced in 5 cases. Of 120 cases of heart disease induction was performed for failing compensation in 3 cases; 2 cases were induced for toxæmia and nephritis, one for progressive disseminated sclerosis, one for progressive tabes dorsalis with paralysis, one for epilepsy, one for arsenical poisoning, and one for acute hydræmiosis. Advice was given as to the avoidance of future pregnancies, and in some cases sterilization was carried out. X rays hold out a promise of effective sterilization in these cases without the risk of operative intervention.

## Methods of Inducing Abortion.

The methods of induction of abortion may be divided into two headings—slow and rapid.

The slow method is much to be preferred, especially in cases of severe wasting disease such as phthisis, where

haemorrhage has a harmful effect upon the recovery of the patient. Induction can be performed by tents, in many cases with successful results and without the onset of sepsis. The dilatation of the cervix by Hegar's dilators and the introduction of a gauze and glycerin drain causes the uterus to empty its contents subsequently with little or no haemorrhage. But it must be remembered that the stimulation of the uterus to contract and expel its contents is not always an easy accomplishment. A small rubber tube or large catheter inserted into the uterus sometimes acts very satisfactorily. In pregnancies in which the foetus is palpable induction may be brought about by passing the rubber tube, or by rupturing the membranes and pulling down a leg.

The rapid method of clearing out the ovum under anaesthesia, as is done in cases of incomplete abortion, is not advisable except in very early pregnancy, owing to the risk of haemorrhage and laceration in a patient already debilitated by disease. It almost comes under the heading of accouchement forcé. The operation of vaginal hysterotomy as described by Mr. Barris seems to be one of risk for a patient who is suffering from active pulmonary or advanced heart disease. The performance of abdominal Caesarean section for removal of a non-viable ovum does not seem to have many arguments in its favour.

## III.—J. D. BARRIS, M.B., F.R.C.P., F.R.C.S., Physician Accoucheur, St. Bartholomew's Hospital.

Dr. EDEN, in his address, has confined his remarks to the indications for the artificial termination of pregnancy before the viability of the foetus. We have now, therefore, to consider the methods by which the pregnancy may be brought to an end when the necessity for so doing has been established. As my remarks on this subject must be limited to a short space of time, they will deal with its broader aspects rather than its details.

The methods at our disposal fall into two groups—slow and rapid.

**Slow Methods.**—These consist of rupture of the membranes; plugging the cervix and vagina; dilatation of the cervix by means of laminaria tents or metal dilators or the small hydrostatic bag; introduction of small bougies; and administration of drugs alone or in combination with these methods.

**Rapid Methods.**—These include dilatation of the cervix, followed by rapid evacuation; vaginal hysterotomy; Caesarean section.

The principles by which we must be guided in our choice as to the particular method to be employed may be stated to be—first, to regard the early termination of a pregnancy as a labour in miniature. We must endeavour, therefore, if possible to make the uterus itself expel its contents rather than that we should drag out the latter course as a routine would involve a greater risk of laceration, of haemorrhage, and of sepsis; nor is the ovum so likely to be removed completely. Secondly, we must bear in mind that we are not dealing with a woman in as good general health as we usually are when inducing premature labour for contracted pelvis, but with a woman whose resistance has been lowered in many cases by some general disease or by previous loss of blood. Our intervention, therefore, should be of such a nature as will entail the least strain on her already lowered resistance and the least risk of injury or further haemorrhage.

The application of the foregoing principles is governed by two factors: (1) The urgency of the need for the termination of the pregnancy—that is, whether a slow or rapid method is necessary. (2) The date of the pregnancy—that is, whether the period of the gestation is before or after the end of the first three months. Of these two factors the former is not as a rule of so much importance as the latter, for this involves the size of the foetal head and the degree to which the dilatation of the cervix may be necessary. This is the essential point, and methods which may be not only legitimate but desirable during the first three months may be unsuitable and even dangerous at a later date.

### *Induction Before the End of the Third Month of Gestation.*

The uterus can be evacuated readily by the rapid method during the first three months of pregnancy. In this case the ovum is small, and its tissues are of no great density; the head of the foetus will therefore be small and easily collapsible. The degree to which the cervical canal will require to be dilated will in consequence not be great. The uterine cavity will not be too large for the finger to be able to explore its walls completely, and the ovum can be separated readily from its attachments.

The slower methods, although satisfying an underlying principle in that they aim at exciting the uterus to contract and expel its contents spontaneously, are not therefore so definitely indicated. Nor are they always to be relied upon at this early date, for they may fail to excite uterine contractions, with the result that repeated manipulations may be necessary, entailing delay and an added risk of sepsis, so that operative measures may be required to complete the process. Furthermore, it is during the early period of pregnancy that the need for the termination of the pregnancy is more likely to be urgent, so that a more rapid method is required.

During the first three months of gestation, therefore, I think you will probably agree that we are justified in advising that dilatation of the cervix and immediate evacuation of the uterus is the best method. A set surgical technique with strict antiseptic precautions is necessary. A laminaria tent may be needed to aid the subsequent dilatation of the cervix by metal dilators. The dilatation should be sufficient to allow the gloved finger to pass, but the finger must not be forced through or severe lacerations in the region of the internal os and lower uterine segment may result. When the ovum has been gently detached by the finger it may be squeezed out of the uterus or withdrawn by the ovum forceps. The instrument must possess no sharp gripping points, otherwise a portion of the uterine wall may be grasped. Perforation of the uterus and the seizure of bowel have occurred. The decidua should, if possible, be separated by the finger, but the use of a blunt curette may be required; the sharp curette should on no account be used. A case has been under my own observation in which the uterine wall had been scraped through and the bowel damaged owing to the use of the sharp curette. When the uterus is empty the bleeding, which is often profuse, should be controlled by massage of the uterus and a hot intrauterine douche. Plugging may be required temporarily to control the bleeding. The anaesthetic employed should not be chloroform; it is preferable to use ether, or gas and oxygen.

### *Induction After the Third Month of Gestation.*

The evacuation of the uterus after the third month of pregnancy is a far more difficult problem. We are now dealing with an ovum which is larger, and its tissues are of greater density. The foetal head will therefore be both larger and harder. The degree to which the cervix must be dilated will now be considerably greater, and, if it is stretched too rapidly, severe laceration at the level of the internal os extending into the broad ligament and dangerous haemorrhage may result. The uterus also is now much larger, and it will not be possible to feel all over its internal surface with the examining finger owing to the size of the cavity being too great. Complete separation of the attachments of the ovum cannot, therefore, be assured, so that serious haemorrhage may accompany the manœuvre and portions of the placenta may be left behind. Since, also, the foetus is easily broken up at this stage of gestation and the cavity cannot be explored with certainty, it is possible that portions of the foetus may be overlooked. The foetal head may become detached and it may be extremely difficult to bring it out through the cervix. Although it is difficult to credit it, cases have been recorded in which the foetal head has been left behind and passed spontaneously subsequently—an occurrence difficult to explain satisfactorily to the patient. These manipulations, involving as they do a greater risk of damage to the maternal tissues, bring in their train also an added risk of sepsis. While, therefore, we are justified in advising dilatation of the cervix and evacuation of the

uterus before the end of the third month, we are not justified in using this procedure after this date. Even at the earlier date this operation is associated with considerable bleeding and is very repugnant, but after the third month it is fraught with such dangerous risks to the mother that its employment is to be avoided if possible.

In the rare instances when it is necessary to evacuate the uterus rapidly after the third month it is far safer, after having dilated the cervix as much as possible, to incise the anterior fornix transversely, strip up the bladder from the front of the cervix, and then divide the anterior lip of the cervix longitudinally so as to expose the uterine cavity. The membranes should now be punctured, the foetus gripped by a leg, and the uterus evacuated. This operation of vaginal hysterotomy enables us to empty the uterus completely with no risk of lacerating the maternal tissues, and is to be preferred at this stage of gestation to an abdominal Caesarean section.

The slower methods of terminating the pregnancy are, however, more usually indicated at this stage. Of these the best is to insert the small hydrostatic bag through the cervical canal after it has been dilated either by means of a laminaria tent or by metal dilators. It is advisable to insert the bag without rupturing the membranes, and its action may be assisted by the use of pituitrin. The other slow methods are not so reliable and may involve repeated manipulations and a greater risk of sepsis. If the pregnancy requires to be terminated on account of a carneous or vesicular mole the insertion of a laminaria tent in combination with pituitrin will usually induce the uterus to expel its contents spontaneously. The use of castor oil and quinine has also been recommended by some authorities, but I have not personally found it so reliable in these two conditions. In the case of a vesicular mole the evacuation of the uterus by abdominal Caesarean section has been employed with very satisfactory results.

### IV.—FREDERICK W. PRICE, M.D., F.R.S.E.,

Physician, National Hospital for Diseases of the Heart; Consulting Physician, Royal Northern Hospital, London.

#### CARDIAC INDICATIONS.

The subject of cardiac affections in relation to marriage, pregnancy, labour, and the puerperium is of great importance to the medical practitioner. He is sometimes consulted by those who suffer from some cardiac affection about the question of marriage, or, in the event of marriage, whether pregnancy should be risked—either with regard to a first child or to further pregnancies. If pregnancy has occurred, he may have to decide whether it should be allowed, if possible, to go to term, and as to the best method of delivery, or whether abortion or premature labour should be induced, and as to the best method of emptying the uterus. Furthermore, the responsibility of the management of the pregnancy, the labour, and the puerperium rests upon him. The subject I have to deal with is limited to the cardiac indications for the termination of pregnancy before the viability of the child. I should also like to confine my remarks to the question of the risk to the mother's life, not dealing with that relating to her health after the puerperium.

It will be readily understood that pregnancy, labour, and the puerperium impose a strain upon the heart, even when the organ is healthy. Various factors contribute to this. During pregnancy there is an increase in the body weight, and in the circulation. The growing uterus gives rise to a gradual increase of pressure in the abdomen. It also causes a gradual raising of the upper level of the diaphragm, and interferes with its descent. The upward displacement of the diaphragm causes the position of the heart to become more transverse, and, as a result, the apex beat may appear in the fourth intercostal space and the left border may be displaced outwards. The chest wall becomes widened (Mackenzie). The combined result of the displacement of the heart, the diminution in the descent of the diaphragm, and the widening of the chest wall is an interference with the free movements of respiration. The foregoing factors together act as a mechanical impediment to the carrying on of an efficient circulation, which increases towards

the end of pregnancy. The result of this is that the heart has more work to do. The displacement of the apex beat and of the left border can be accounted for, at least partially, by the displacement of the heart. It is generally believed that it may be due partly to dilatation. Mackenzie has shown that this affects more especially the right side of the heart, and that not infrequently, even in healthy subjects, a certain amount of relative tricuspid incompetence may occur from time to time according to the condition of the patient. It is necessary to point out that what are called "crepitations" heard over the bases of the lungs, which disappear after a few breaths, are not indicative of oedema of the bases of the lungs; when they do not disappear after deep breathing they are indicative of oedema, collapse, pneumonia, or bronchopneumonia. A certain amount of shortness of breath on exertion after the twenty-eighth week of pregnancy is an almost normal occurrence. Oedema of the lower extremities, usually slight, but occasionally very considerable, may occur during pregnancy. This may be due to pressure of the uterus on the pelvic veins, but when it extends above the knees it is the result of albuminuria, or, less frequently, of cardiac failure. Varicosity of the veins of the lower extremities and of the vulva may be observed, as the result of pressure of the uterus on the pelvic veins. It is therefore to be observed that displacement of the apex beat and of the left border of the heart, increased transverse diameter of the area of cardiac impairment, the occurrence of a systolic murmur with its point of maximum intensity in the tricuspid area, crepitations over the bases, disappearing after a few breaths, a certain amount of shortness of breath after the twenty-eighth week, oedema below the knees, and varicosity of the lower extremities and of the vulva occurring during the course of pregnancy are not necessarily indicative of cardiac failure. An additional strain is thrown upon the heart during labour. The first stage does not involve much strain; it is the second stage which involves most strain. During the third stage there is a fall in the blood pressure, with a coincident tendency to collapse. Lastly, the puerperium involves a certain amount of strain on the heart. Acute cardiac failure, including acute pulmonary oedema, may occur immediately, or a few days after delivery. Notwithstanding the foregoing—taking the cases as a whole—the subjects of cardiac affections stand child-bearing surprisingly well.

It is of fundamental importance to recognize that the essential cause of cardiac failure lies in the heart muscle. If that be so, the importance of the relation which chronic valvular disease and disturbances of the cardiac mechanism, such as auricular fibrillation, bear to the myocardium can be readily understood. In a case of chronic valvular disease it is of the utmost importance that we should endeavour to ascertain whether, along with the valvular lesion, there are coincident changes in the myocardium, or blood vessels, or both, and if so, in what degree. But while I would emphasize this, it is necessary to point out that a valvular defect is a mechanical impediment to the work of the heart muscle, and may be of great importance in itself. In attempting to form a prognosis in any given case of chronic valvular disease, the nature and degree of the lesion, its mode of origin, the degree of any existing cardiac failure, the existence of complications, and the risk of sudden death, require consideration. Among the points which may be of assistance in trying to form an estimate of the extent of the lesion are to what extent the character of the pulse and the blood pressure are modified, and the size of the heart; and, in the case of aortic incompetence, the pulse pressure, and, in the case of mitral stenosis, the length of the presystolic murmur, and the presence and length of a diastolic murmur.

I have been surprised at the comparative frequency with which chronic myocardial disease occurring by itself is missed—in my opinion, due to a lack of appreciation of the great importance of determining accurately the size of the heart. Now, with regard to whether the myocardium is involved—either accompanying chronic valvular disease or by itself—it is of extreme importance to ascertain how the heart responds to effort; in other words, the amount

of physical exertion in which the patient can indulge without experiencing symptoms of cardiac distress. In the great majority of cases the first indications of heart failure are symptoms of cardiac distress on exertion, and it is only afterwards that objective signs—such as increased pulse rate, dilatation, or dropsy—appear. These symptoms recur as the result of less and less effort, until ultimately some or all of them are present during rest, and objective signs also become evident. It might be helpful if I indicate what, speaking broadly, and without reference to pregnancy, may be regarded as clinical manifestations of four degrees of cardiac failure—namely, slight, moderate, severe, and extreme.

*Slight.*—Shortness of breath, palpitation, exhaustion, and, it may be, precordial pain, on exertion which the patient formerly could undergo without experiencing this.

*Moderate.*—Shortness of breath, palpitation, and, it may be, cyanosis, on moderate exertion, such as walking quickly on the level; puffiness round the ankles in the evening; some degree of increased rapidity of the pulse while at rest; slight enlargement of the liver.

*Severe.*—Shortness of breath on slight exertion, such as walking at the ordinary rate on the level, or on changing position in bed; cyanosis while at rest; a considerable degree of oedema of the lower extremities in mitral cases, and a moderate degree in uncomplicated aortic cases; a considerable degree of tachycardia while at rest; oedema of the bases; a moderate degree of hepatic enlargement; albuminuria; orthopnoea; cardiac asthma.

*Extreme.*—Continuous shortness of breath; severe dyspnoea on slight exertion; marked cyanosis while at rest; general anasarca in mitral cases, and a considerable amount of oedema of the lower extremities in uncomplicated aortic cases; oedema of the serous membranes; much hepatic enlargement; pulsus alternans in the absence of a severe grade of tachycardia.

A point of the utmost prognostic importance in angina pectoris is the ease with which the pain is provoked, and whether it occurs even when the patient is at rest. It remains to add a few observations. The first sound may be short, sharp, and clear, and diminished in intensity when the contractile force of the ventricle is reduced. What is called the tic-tac heart beat or foetal rhythm signifies a greatly impaired vitality, and is often of grave omen. What is termed the gallop rhythm indicates either a failing heart muscle, or a bundle-branch block, or possibly intraventricular block, and is almost always of very unfavourable import.

We now pass to the consideration of the individual cardiac affections.

*Irregular Action of the Heart.*—I am here referring to irregular action of the heart in itself—that is, without reference to the cause or the condition with which it may be associated. What is called sinus irregularity and also extra-systoles may be disregarded. The three grades of auriculo-ventricular block, bundle-branch block, and intraventricular block are indicative of myocardial damage, and in each case it depends upon the degree of associated myocardial disease. It is necessary, however, to add the following: In complete auriculo-ventricular block, if the patient is subject to syncope attacks—especially if during the period of development of the condition—pregnancy should be terminated. The prognosis of bundle-branch block is usually very unfavourable. Intraventricular block is almost always of grave import, and pregnancy should be terminated. From the point of view of our discussion there are two kinds of pulsus alternans—namely, one in which the condition is associated with a severe grade of tachycardia, and the other in which it is not. In the latter event it is an indication of extreme exhaustion of the heart muscle, and should be regarded as an imperative call on the part of the heart for rest—complete and prolonged. If this is not possible, or if it is not successful, pregnancy should be terminated. With regard to auricular fibrillation, it depends upon the ventricular rate, the degree of any existing cardiac failure, and the response to digitalis therapy. If there is an absence of tachycardia, or tachycardia is at the most moderate, or tachycardia of more severe grade is well controlled by digitalis, and if the degree of cardiac failure is at most moderate, pregnancy may be allowed to continue; while if there is severe tachycardia uncontrolled by digitalis, or severe cardiac

failure—especially if it increases in spite of adequate treatment—pregnancy should be terminated. In the case of persistent auricular flutter, it depends entirely upon whether treatment for terminating the condition is successful or otherwise. With regard to an individual who is the subject of paroxysmal tachycardia, it depends chiefly upon (1) the existence of chronic myocardial or chronic valvular disease, and, if either be present, its nature and degree; (2) to a less extent, upon the average duration, the ventricular rate, and the degree of cardiac failure during former attacks; and (3) the success attending treatment for the prevention of the recurrence of the attacks.

*Chronic Valvular Disease without Reference to any Existing Cardiac Failure.*—It is generally agreed that, with regard to pregnancy, mitral stenosis is the most serious form of chronic valvular disease. This lesion puts a greater strain upon the right side of the heart, pulmonary complications are frequent, and, as I have already pointed out, cardiac dilatation during pregnancy affects mainly the right side of the heart. It should, however, be noted that there may be other factors, such as the frequent association of auricular fibrillation, and, of less common occurrence, chronic adhesive pericarditis. It is justifiable to terminate pregnancy when the degree of the lesion is severe—as evidenced by a very small pulse together with a murmur beginning immediately after the second sound and continuing all through ventricular diastole and auricular systole, especially if the lesion is not the result of antecedent acute endocarditis and is progressive, or there is also auricular fibrillation, mitral incompetence, or chronic adhesive pericarditis. In mitral incompetence pregnancy may be allowed to proceed, unless the degree of the lesion is very severe. The same applies to aortic stenosis when it is due to antecedent acute endocarditis and not the result of primary chronic endocarditis. In aortic incompetence it is permissible to terminate pregnancy when the degree of the lesion is severe, as evidenced by a great alteration in the character of the pulse and of the blood pressure and the size of the heart, and much more so if the lesion is not due to antecedent acute endocarditis; or if the patient is subject to severe syncopal attacks associated with physical exertion. In the case of congenital morbus cordis, it depends upon the size of the heart and the degree of subjective symptoms. I may say that I have known of several patients with patent ductus arteriosus who have borne several children well.

*Chronic Myocardial Disease by Itself.*—In the consideration of this condition, the size of the heart and whether the patient is subject to syncopal attacks are important. It is in chronic myocardial disease that the modifications of the cardiac sounds and cardiac cycle, the presence or otherwise of auriculo-ventricular block, branch-bundle lesion, intraventricular block, auricular fibrillation, auricular flutter, paroxysmal tachycardia, and the degree of cardiac failure are of especial value.

*The Existence and Degree of Cardiac Failure.*—I am fairly confident that with regard to cardiac indications the usual practice of most of my audience is to be guided by the existence and degree of cardiac failure, and I can quite understand this. Whenever indications of cardiac failure present themselves during pregnancy, four points should invariably be taken into consideration—namely: (1) the degree of cardiac failure; (2) at what stage of pregnancy these have supervened; (3) the immediate cause of the present attack; and (4) the response to treatment. With regard to the third of these, inquiry should be made as to whether this can be attributed to some temporary cause, such as a period of undue physical strain, or some intercurrent malady, or whether the symptoms have gradually appeared without any such cause; in the latter event the prognosis is less favourable. In the case of the first degree of cardiac failure, at whatever stage it occurs, in all probability it will be possible for the patient to proceed to full term without risk to life. If the second degree occurs during the first half of pregnancy—more especially during the first three months and without some temporary cause for the cardiac failure—it is unlikely that the patient will be able to proceed to full term, but an attempt may be made; if it occurs in the second half, it is probable that she will. In either

case rest is imperative for a period which may even extend to some months. If the severe degree occurs in the first half of pregnancy, it is exceedingly improbable that the patient will be able to proceed to full term; but even in this case, providing she is able and willing to rest in bed for some months, it is surprising how often a favourable issue will follow; if it occurs in the second half, an attempt should certainly be made. If an extreme degree is present at any stage, pregnancy should undoubtedly be terminated. It remains to add that, except in the case of an extreme degree of cardiac failure, it should be accepted as a general principle that pregnancy should not be terminated until a reasonable period of rest and other therapeutic measures have been tried; while, on the other hand, in the case of the second and third degrees, if proper treatment, carried on for a reasonable period, is not attended by at least a certain measure of improvement, or if a relapse occurs, the termination of pregnancy should be more favourably considered, especially in the case of mitral stenosis.

Lastly, I would suggest that in any case in which it has been decided to terminate pregnancy an attempt should first be made to treat the existing cardiac failure, in the hope of affording a better chance of a favourable result of the induction of abortion or premature labour.

#### V.—ROBERT HENRY COLE, M.D., F.R.C.P.,

Physician and Lecturer on Mental Diseases,  
St. Mary's Hospital, London.

##### THE PLEA OF INSANITY.

INSANITY during pregnancy is a somewhat rare affection, comprising less than 1 per cent. of the total incidence of insanity in women. Although cases are occasionally to be seen in our public mental hospitals where the pregnancy invariably runs its usual course, our individual experience of cases in consulting practice must necessarily be small. Yet pregnancy accompanied by mental disorder of a mild type, as exhibited by subacute depression, morbid yearnings, or transient perversions of one kind or another, is not uncommon, and one would expect that such disorder might easily pass over the border-line, which, indeed, happens in exceptional cases. I think most of us are agreed that when those cases develop, as they usually do, in the earlier months of pregnancy they often clear up after a few weeks and generally before delivery.

The fact that an insane woman has unfortunately been allowed to conceive does not alter her mental condition, as I have observed in the case of a wife suffering from delusional insanity who lived at home with her husband. How far insanity is the outcome of pregnancy it is difficult to say with precision. The association is much clearer as regards cause and effect when mental disease ensues after labour or during lactation. Nature, indeed, ever mindful of the continuance of the race, endows incipient motherhood with increased vitality which counterbalances the anxiety, discomfort, or stress of the pregnant state, and cases of insanity during these months seldom arise in the absence of bodily ill health or a bad inheritance or previous attacks. It would seem, therefore, that a psychosis might eventuate if the patient were not pregnant at all. In the later months of pregnancy, if insanity develops, experience teaches that in recoverable cases it usually persists for some time after the birth of the child, whether the patient be prematurely delivered or not.

In the case of the unmarried girl who has been wronged, or has gone wrong and finds herself pregnant, medical advice is sometimes sought to terminate the condition to alleviate her mental distress, apparently in complete ignorance of the law governing these matters. Illegitimacy or desertion is regarded as one of the minor factors in puerperal cases; but the desperate mental state which the unfortunate single girl sometimes develops, which doubtless would disappear by removing the cause, is harrowing to one's feelings, but I have so far seen no such case in which operative intervention would be justified. It cannot be said that suicidal threats or even attempts *per se* indicate insanity. We are sometimes consulted regarding a young married woman who, finding herself pregnant, is in fear of childbirth, and says she would rather die than

go through with it; she is generally of an hysterical temperament. In spite of threats of self-destruction I believe the right course is that she should be managed by nurses, and that interference with the pregnancy is scarcely ever justifiable until at any rate the child is viable, when I have known Caesarean section and tying of the tubes meet the requirements.

There is another class of phobic cases belonging to the obsessional group. If in such a case the medical opinion formed as the result of consultation, that the morbid fear of death as the outcome of pregnancy is so overpowering as to endanger the patient's life, operative intervention may be indicated. I have seen such a case similar to that quoted by Dr. Eden which he rightly denotes psychopathic. The patient was an elderly primipara, and her fixed idea was having such a profound influence on her bodily health that it seemed possible that she might not survive—and therefore premature labour was induced at the fourth month, as psychotherapy had failed.

Concerning cases in which a previous attack of insanity (or even more than one) has occurred, especially after labour and in borderline cases with bad family histories, I feel obliged to dissent from the view expressed in Dr. Eden's paper—that labour should be induced before the child is viable, unless there are other indications regarding the patient's bodily health. It is open to doubt whether mental disorder would be less liable to occur by premature intervention than after the seventh month or at full time. It is true that we advise that a woman with a strong family history of insanity or one who has had an attack of puerperal insanity should as a rule avoid the risk of becoming pregnant again, but, should this happen, I hold the view that the condition should be allowed to continue. It must be acknowledged that the chances are more than even that there will not be a recurrence of mental trouble. If, however, unfortunately this should occur, it must be remembered that the recovery rate is fully 75 per cent. in these puerperal cases, and the question of some such procedure as obliteration of the tubes to prevent future pregnancies might be considered.

I now allude to a question which apparently is receiving reconsideration. The incident occurs now and then where an insane husband, home on leave from an institution, results in his wife falling pregnant. She becomes distracted at the prospect of bearing a child who she thinks may be mentally defective or become afflicted, and she is haunted by this idea, which becomes a veritable obsession. The first case of this kind in my practice occurred many years ago where the husband had a short remission in general paralysis and the mental state of the wife caused anxiety. This I was able to disperse and she went to full term, and the boy that was born subsequently won an open scholarship at a public school. In the case of a lady who was sent to consult me lately the husband, a chronic delusional patient with a wretched family history, was allowed home on leave from a mental hospital with the same result, that his wife conceived and she was in terror of bearing an afflicted child. Again I considered the grounds for intervention quite inadequate, but I have heard later that a "natural" miscarriage has taken place—whether in this country or abroad I know not. My advice has similarly been sought regarding the fate of the unborn where one of the parents was a chronic epileptic and contraceptive measures failed, but we are yet without sufficient eugenic data to yield to the plea that a pregnancy should be terminated to prevent the birth of a child that might be mentally defective or diseased.

With regard to the types of insanity during pregnancy, my experience is that manic-depressive and dementia praecox are most usual. Should exhaustion symptoms ensue in the first months of pregnancy owing to the severity of the mental disorder I very much doubt whether the termination of the pregnancy would be beneficial, and it might, indeed, make matters worse. Refusal of food, insomnia, and suicidal tendencies are symptoms that require the most urgent attention, but in my view the pregnancy should be allowed to continue. Eliminary treatment and baths are particularly useful, and a change from home surroundings is often beneficial, especially,

as sometimes happens, when the presence of the husband is not helpful.

Dr. Eden's paper, coming from so high an authority, has given us food for reflection. It is no doubt agreed that each case should be considered on its merits, and that we should guard against any narrow-minded attitude. Yet I feel there is a danger that our sympathy can be unduly extended and may warp our judgement, if too much stress is placed on the possible prejudice to the patient's future health. In many cases this is problematical, at any rate having regard to mental health, and it seems to me that it might be capable of being construed in such an elastic sense and applied to improper cases, so that, if generally accepted, it would lead to abuses or laxity in practice, and result in serious comments on our privileged position as medical practitioners.

It cannot surely be granted that an embryonic child should be sacrificed because the mother has had repeated pregnancies at short intervals and is unwilling to face the ordeal. The proposition that some parents hold, that their unborn child should be completed or not as they like, cannot be squared with our ethical or legal standards. We as doctors have no right to curtail a pregnancy before the child is viable, except for bona-fide reasons, which I believe still to be limited to the ill health of the mother jeopardizing her life, and any widening of this principle by entertaining other excuses I regard as contrary to generally accepted opinion even with the advance of medical and sociological knowledge.

Our duty, no doubt, is first towards the patient, but we must bear in mind that she is carrying the germ of another being which demands our consideration, and which the State safeguards by legislation. Whatever may be said as regards tubercle, renal or other disease which may interfere with the life of the mother during pregnancy, it is the exception rather than the rule with brain or mental conditions unless accompanied by disease of other organs.

#### VI.—H. HARVEY EVERS, M.S., F.R.C.S., Newcastle-on-Tyne.

It seems to me that unless we are extremely careful the tendency of this important discussion will be to multiply the indications for what we all agree is a very undesirable and distasteful operation. This would be a most dangerous impression to create at a meeting of such eminent obstetricians, whose most important function, in these days, is the safeguarding of the human orum. I would submit, therefore, that we should endeavour to inculcate and emphasize extremely conservative views, and lay down as few indications as possible for this operation of "embryocide" or "oricide." No purely speculative reasons or excuses for emptying the uterus should be entertained for one moment. The procedure should be most rigidly confined to those conditions where it has absolutely proved its value beyond any shadow of doubt. These conditions, I would submit, are extremely few.

Furthermore, I would suggest that the burden of proof of indication or justification rests always with those who recommend the operation, and many of the reasons given thus far have been largely speculative and very unconvincing. Holding these views, I will perhaps be tolerated if my criticisms are largely of the destructive variety.

Dr. Watts Eden even raises the ethical question "as to what extent we as doctors have the right to insist that a woman should pass through an ordeal which she is unwilling to face"—though why he should call pregnancy and labour "an ordeal" it is difficult to understand. Surely this question is neither ethical nor professional, but strictly legal and moral; and such a doubt raises the most dangerous possibilities, as the vast majority of women with one or two children are unwilling to face this so-called "ordeal." Moreover, Dr. Eden's instance of the distinguished barrister's wife is, to my mind, most damning evidence against such a point of view. A patient's or her husband's reasons for getting rid of an ovum should never be accepted, as there will generally be some selfish or sinister reason undisclosed. Again, with regard to psychopathic disturbances, Dr. Eden's instance, to my mind, merely serves to emphasize the folly of warning patients

against subsequent pregnancy on unjustifiable grounds; and the emptying of that patient's uterus was really adopted ultimately as a means of circumventing what was originally a professional error. Surely nothing could be worse than the mental torture of illegitimate or illicit pregnancy! Are we, then, to consider ourselves justified in terminating these?

#### *Tuberculosis.*

There is no convincing argument in favour of interference in these cases. Working in conjunction with Dr. Dickinson, I have details of 43 sputum-positive patients who have had one or more pregnancies since 1913. Of these, 19 have died, but the total duration of illness of these cases was not below the average duration of phthisis in females of the same age period; 11 of these cases were victims of that acute type of disease which occasionally supervenes on labour, or at all events is only detected after a confinement. The prognosis in these acute cases, quite apart from pregnancy, is always bad, and there is no evidence whatever to show that emptying the uterus early would avert the condition.

With regard to the offspring, Couvelaire's statement, quoted by Dr. Eden, is certainly not borne out by the most recent views, and it seems scarcely sound ground for depriving the ovum of its life. Surely a much more logical plan is to segregate these infants as soon as they are born. This is done by the Association for Familial Placement, founded in Paris by Professor Léon Bernard and Dr. Detre; under its auspices no case of congenital tuberculosis has been discovered amongst the young patients, and the mortality from all causes is not above the average for artificially fed infants. Moreover, recent inoculation experiments by Calmette and his co-workers in France, Belgium, and New Guinea have made a great advance in the prophylaxis and have opened up a new avenue for the prevention of tuberculosis in children born into a tuberculous household.

#### *Heart Disease.*

Intervention before the child is viable is purely speculative and not justified. Pregnancy by itself cannot do any harm until the uterus forms a tumour large enough to cause embarrassment. The early failures of compensation are not due to the pregnancy itself and can be overcome by the ordinary medical measures adopted in such cases. In this way an overwhelming majority of the cases, even those which seem quite hopeless, can be forced over to the stage of viability of the child, when delivery can be effected successfully by Caesarean section, under spinal anaesthesia if necessary.

#### *Missed Abortion.*

No intervention is indicated unless the patient is very anxious to proceed as soon as possible to a further pregnancy, or unless the retained mole has become infected. Otherwise intervention is meddlesome and, though usually safe, has been known to be fatal.

#### *Chronic Nephritis.*

Here we have very definite scientific proof that in some of these cases the pregnancy has a definite baleful influence on the renal function, and can inflict permanent damage. In view of these definite findings we are therefore justified in terminating pregnancies in cases showing severe clinical manifestations such as general oedema, high blood pressure, and lung complications, and especially if accompanied by definite positive biochemical findings—for example, a material rise in blood urea and a progressively poor response to the urea concentration test. A serious attempt, however, should always be made to carry these patients on by medical measures until the child is viable. Albuminuric retinitis is, of course, an absolute indication for terminating pregnancy.

#### *Pernicious Vomiting.*

The rogue of emptying the uterus in these cases is progressively on the wane, and one ventures to hope that it may ultimately disappear. We are all in agreement that prompt and proper treatment of all cases of abnormal vomiting makes the induction of abortion an extremely rare necessity. Moreover, the results of treatment of bad cases by induction are by no means good, deaths occurring occasionally even after spontaneous abortion. Quite

recently a patient was sent to us at three months, having been told that her uterus must be emptied, as it had been for a similar condition at the previous pregnancy. On admission she was wasted, looked very ill, had a furred tongue, and a pulse of 130, and was demanding that her operation should be done forthwith. She got perfectly well on purely medical treatment, and is now seven and a half months pregnant.

In conclusion, I have been requested by Professor Ranken Lylo to submit to this meeting the three following good reasons why the induction of abortion should now practically never be considered:

1. An enormous importance is attached to the value of intrauterine life at the present time.
2. Great improvements in medicinal treatment of most complications have taken place in recent times.
3. The dangers originally urged against pregnancy under certain conditions were mostly of a speculative nature and mostly groundless.

#### GENERAL DISCUSSION.

Dr. R. A. Young (London) remarked that tuberculosis seemed always to arouse controversy, and that it suffered from a plethora of slogans and aphorisms. One of these—that of Dubois—popularized by Osler, had been quoted by Dr. Eden. He would mention two others. It had been said of the tuberculous: "For the virgin, no marriage; for the married, no pregnancy; for the pregnant, no childbirth; for the mother, no suckling." The other aphorism was that during pregnancy there was often latency or quiescence of tuberculous disease, which flared up acutely after delivery. Before elevating these statements to the dignity of laws or rules of practice, it would be wise to inquire if there were any statistical bases for them. It would then be found that until recently there had been few attempts to investigate the stage and activity of the disease in relation to pregnancy. Recent statistics would seem to show that in cases with arrested disease a large proportion weathered pregnancy and even repeated pregnancies successfully, given due care, especially after childbirth. In active cases, on the other hand, the risk was very considerable, and was the greater the more advanced and the more active the disease. It was true that sometimes during pregnancy there was a temporary lull in the disease, but this was by no means always the case. In active cases the question of abortion had to be considered if the patient were seen before the fourth month. In his experience, those who saw most cases of pulmonary tuberculosis least often recommended abortion in treatment. He himself had rarely advised it, and had generally regretted it afterwards when he had done so. It should not be forgotten that operation, except urgently necessary operation, was inadvisable in active tuberculosis, and that anaesthetics, other than gas and oxygen, were fraught with real danger of spreading the disease or of rendering latent disease active. It was also an open question whether the after-effects of abortion were not in many cases as harmful as those of labour. In any case, abortion should only be performed in such patients after consultation between the general practitioner, the physician, and the gynaecologist, and after due consideration of the family and personal histories, the symptoms, physical signs, the x-ray appearances, temperature range, sputum records, and possibly blood reactions. There were certain complications, however, which might weigh heavily in the deliberation and justify intervention, notably laryngeal or intestinal involvement. Abortion in quiescent or arrested cases was illogical and was more likely to do harm than good. An important point, which was often lost sight of, was that it was quite possible to employ the ordinary forms of treatment, including artificial pneumothorax, during pregnancy. Too often treatment was interrupted or neglected during this period, and it was only after childbirth that treatment was resumed, often when it was too late to be helpful. He urged most strongly the importance of prolonged rest under open-air conditions after the birth of the child. In conclusion, having condemned aphorisms, he wished to be thoroughly illogical, and propound two

for consideration—one borrowed from Pinard: "Treat the disease and manage the pregnancy." The other he would like to think original, though it was perhaps unconsciously stolen—"Prevention is better than abortion."

Dr. R. C. BUIST (Dundee) said that the appeal of the consultant to the general practitioner was, "When you refer a patient for consideration of the question of terminating pregnancy do not foreclose the question and prejudice the issue by expressing an absolute opinion."

Dr. BINNIE DUNLOP (London) was one of those who did not feel that there was any ethical or moral objection to terminating a pregnancy before the viability of the child. He considered it an indication of the desirability of this merely if the woman wished it, or rather if the woman could not be persuaded to desire the pregnancy to go on. It was not in the public interest that medical practitioners should not be free to terminate a pregnancy on economic and eugenic grounds as well as on purely medical grounds. It would be better for the race if undesired children were not born. An appalling amount of unhappiness and ill health resulted from medical practitioners not being legally perfectly free in the matter.

Dr. J. S. ENGLISH (Singapore) had never performed anterior hysterotomy. He had always found dilatation to No. 12 and packing with tents sufficient; the ovum being removed in twenty-four hours with ease. After twenty weeks' pregnancy he always used a No. £3 stomach tube, which could be easily sterilized—an obvious advantage over the usual gum-elastic bougies which were generally advocated. Before being shown this method by Dr. FitzGibbon in the Rotunda Hospital he had a good deal of experience of Kraus's method, and many times had to remove the bougies and reinsert them, possibly three times. Using the stomach tube, however, he had yet to see the case where labour had not come on in twenty-four hours at most. The only difficulty was when the tube touched the membranes and a sense of resistance was felt. That was overcome by rotation of the tube on its long axis, and the tube then slipped in easily. The whole tube was inserted and removed only when the cervix was half dilated. If any difficulty was experienced in its removal the tube could be pushed past the presenting part and would be delivered after the child. An anaesthetic was only necessary in primiparae.

Mr. L. C. RIVETT (London) had not had much experience of pulmonary tuberculosis, but such cases as he had seen led him to believe that the puerperium was more detrimental than the pregnancy, and that it was as much so after a three months' abortion as after full term; termination of pregnancy was therefore very limited in this complication. Dr. Eden said that it was not to the advantage of the community that children should be born who had seven times the normal risk of contracting phthisis. Was it the province of the doctor to decide this? If so, what about syphilis? He suggested that if any condition rendered it inadvisable for a woman to become pregnant the Fallopian tubes ought to be tied, or the ovaries treated with x rays. He raised the point of gross deformity of the pelvis or tumours which absolutely precluded delivery *per vias naturales*. If the patient refused to submit to Caesarean section at term, were they justified in terminating the pregnancy early? or was it their duty to insist on Caesarean section later? As regards cardiac lesions, he was in agreement with Dr. Price's remarks. At Queen Charlotte's Hospital many patients were admitted in a state of extreme cardiac failure, and died in spite of any medical treatment, either undelivered or after delivery—sometimes six weeks after delivery. His experience in this class of case made him conclude that cardiac failure was the most serious complication of pregnancy. He advised a miniature Caesarean section—in opposition to Professor McIlroy—at the same time ligaturing the tubes. Patients stood this operation well in early pregnancy. He preferred general anaesthesia to spinal, as spinal anaesthesia lowered the blood pressure in cardiac cases. Every pregnancy was a strain on the diseased heart, and left it worse than previously; the

aphorism of Dubois, quoted by Dr. Eden, was particularly applicable to heart disease. He called attention to polycystic disease of the kidney—where one kidney had been removed and pregnancy subsequently occurred—as an indication to terminate pregnancy. In reply to a question by Mr. Norman Lock (Exeter), Mr. Rivett stated that he did not think Caesarean section at term in cases of cardiac failure had any advantages over normal labour; the patient was just as likely to die after either.

Mr. NORMAN LOCK (Exeter) said that, in his experience, a well given general anaesthetic was well borne by patients with heart disease, even when advanced, and therefore suggested that Caesarean section would be the best method of treatment of these patients, thereby avoiding the muscular strain and exertion of labour.

The PRESIDENT remarked that the importance of the discussion was obvious when it was realized that, as soon as the papers read and the remarks made were published in the BRITISH MEDICAL JOURNAL, medical practitioners would have at their disposal the collective opinion, as to when abortion should or should not be induced, of some of the greatest experts in their own special line of medicine—an opportunity which, as far as he remembered, had never occurred before. The President deprecated most strongly the reprehensible conduct of telling a patient that in no circumstances must she ever have another child, and this without seeking the opinion on this point from a colleague. He was consulted not infrequently by patients who were most anxious to have more children but dared not, or if they again became pregnant implored for abortion to be induced. Why? In the majority of cases for such unwarrantable reasons that since there was a bad post-partum haemorrhage last time a fatal one would probably result in another labour; or again, as he had many times been told, because the perineum having ruptured once would be sure to rupture worse the next time. There were very few indications for which, a patient having had one child, should be advised not to have a second. Excluding legitimate causes for the induction of abortion, the experience of the President, with regard to those women who had been told that on no account must they have another baby, was that the next labour was perfectly normal.

A sharp haemorrhage in the early months of pregnancy did not by any means indicate that the ovum had been destroyed, and great care must be taken, as far as was possible, to make sure that the ovum was dead before emptying the uterus. The President had a patient who bled on and off for nine weeks, during which time there were three serious haemorrhages—one to start with; the second in three weeks, after the bleeding had stopped a week and the patient was allowed out of bed; and the third, which was the worst of all, in seven weeks, after bleeding had stopped a week, this taking place as the patient walked from her bedroom, about four yards, to a couch in the adjoining room, the bleeding being so profuse that the carpet was completely spoilt. The patient and her husband being most anxious to have a child, a further trial of rest was given, and at the end of forty weeks the patient gave birth to a very healthy 9 lb. child.

The President quite agreed that if abortion had to be induced before the fourth month it should be done by dilatation of the cervix and removal of the ovum. He was not afraid of haemorrhage as the uterus was small and could be easily controlled. After the fourth month, however, the difficulties and dangers increased with the length of pregnancy, and it was much preferable, if possible, to induce the abortion by the slow method. If a quick method was necessary, then the speaker thought that unless the practitioner was well accustomed to operating in such cases, he would be wise to avail himself of the assistance of someone who was. The dangers of haemorrhage, laceration of the uterus, retention of the foetal head, necessitating prolonged efforts to get it out, were all very real dangers, and in most of these cases a vaginal hysterotomy was the best and safest treatment; it was an operation which required great skill.

The President had used the stomach tube many times for inducing labour, and was very pleased with this method; he

felt convinced, from his experience, that it was a quicker and more certain method than that of bougies. He remembered that they were only dealing that morning with the induction of abortion, but he had introduced this subject because he thought it might be of interest for them to know that on the last three occasions when using the tube, although it went in easily, very smart bleeding took place, which did not stop till the tube was removed. These were not cases of low implantation of the placenta. The tube having been removed and inserted in another position and the vagina packed tightly, no further bleeding occurred and the children were born alive.

Those present had had the advantage of listening to views of great experts in their own department of medicine—Dr. Young on tuberculosis in pregnancy, Dr. F. Price on heart disease, Dr. Cole on mental disease, and Dr. Eden, Professor McLroy, and Dr. Barris; and what he had been most impressed with, and he ventured to think also those present, was the great value of team work when dealing with cases such as those that had been discussed.

Professor McILROY, in her reply, advocated sanatorium treatment for the pregnant woman suffering from phthisis.

Dr. BARRIS, replying, said that he understood that Professor McLroy, while she agreed with him as to the necessity of using slow methods for the termination of pregnancy after the third month, did not agree with rapid evacuation of the uterus before this date. He sympathized with this view, and indeed was prepared to agree if it could be avoided. But what was the alternative? Professor McLroy advised the use of laminaria tents, or metal dilators together with the glycerin gauze pack. But she admitted very fairly that it was possible to dilate the cervix as far as No. 16 metal dilator without bringing about uterine contraction. Now this was a damaging admission, for it formed the main point of their trouble with the slow methods early in pregnancy. They were so unreliable, they might need to be repeated, there was the inevitable risk of sepsis, and an anaesthetic and operation might have to be resorted to eventually in order to empty the uterus. All this delay when the urgency for the need of termination of pregnancy was great might be detrimental to the interests of the patient. For this reason, and because the uterus could be emptied fairly easily, he thought it was better to adopt the rapid method before the end of the third month. With regard to the use of the oesophageal tube after the sixth month, he had employed it on numerous occasions with satisfactory results for induction of premature labour, but had no experience of its use prior to the twenty-eighth week. He did not see, however, why its use should not be extended to include a somewhat earlier period provided that the uterus was sufficiently enlarged. He had not found that spinal anaesthesia for Caesarean section in patients suffering from morbus cordis had been attended with any serious fall in the blood pressure, to which Mr. Rivett referred, and regarded this method as very suitable in severe cases of this description, but as a general rule he had found patients suffering from morbus cordis bear labour surprisingly well.

Dr. EDEN, in winding up the discussion, said that he had always regarded himself as orthodox, even conservative, until he wrote this paper. He thought that a combined discussion between the obstetricians and the psychiatrists would be profitable. He would never interfere in a case of phthisis except on the advice of a physician. He advocated broad views on the subject of what had been called foeticide—the rigidity of the views of the medical profession drove people to the abortion-mongers. The public held very decided views as to the importance of their own opinions. It was left entirely to the profession to say in what circumstances a patient should have a pregnancy terminated. In regard to the question of inducing abortion when they thought that the child was going to be diseased, they could not divest themselves of all responsibility for the health and well-being of the child yet to be born. Neither could they compel a patient against her will to go to full term and undergo Caesarean section on account of a tumour such as had been referred to by Mr. Rivett.

## The Sections.

### BRIEF SUMMARY OF PROCEEDINGS.

(Concluded from page 203.)

#### SECTION OF MEDICINE.

Thursday, July 22nd.

##### BLOOD TRANSFUSION IN DISEASE.

SIR HUMPHRY ROLLESTON opened a discussion on blood transfusion in disease with a brief historical note, and then referred to the observation on the length of the survival of the transfused blood in the recipient's circulation, and passed on to the post-transfusional reactions produced in the recipient. Assuming that typing of the blood was correctly done and that by a proper technique severe reactions due to gross incompatibility, embolism, and pulmonary oedema were avoided, yet reactions would sometimes occur and it was impossible to foretell them. Possibly the divisions between the four blood groups were not really as sharp as they appeared to be, and their *in vitro* tests might not be sufficiently delicate to detect slight degrees of incompatibility; Doan's suggestion that there is in some cases an incompatibility between plasma and leucocytes was also mentioned. Reactions were more commonly seen after a large transfusion than after a small one, and after repeated injections than after a single one; repeated transfusions from the same donor were especially liable to produce reactions, possibly owing to the production of anaphylactic shock. Anticoagulant, especially citrate, had been blamed by some in this respect. According to Kordenat and Smithies there were three kinds of reaction—acute, delayed, and systemic or constitutional. The speaker next mentioned the variety of ways in which blood transfusion might do good, and then dealt in greater detail with the indications for blood transfusions in particular diseases. In acute anaemia from haemorrhage its life-saving power was generally admitted; in gastro-intestinal haemorrhage perhaps its value was more debatable. In chronic or repeated haemorrhages blood transfusion often made possible or more safe operative procedures for the cure of the main condition; this was particularly the case in gynaecology. In haemorrhagic diseases blood transfusion might supply the missing thrombogenic factor—for example, the platelets in purpura haemorrhagica—and a haemostatic effect was obtained in haemorrhage of the newly born, haemophilia, and jaundice, although in the latter this effect was by no means constant. In pernicious anaemia it was difficult to assess its value owing to the natural irregular course of the disease; chronic cases with remissions seemed to do better than recent acute ones. In leukaemia there was little real evidence that blood transfusion was of any value, though in a few cases of the chronic lymphoid type some improvement had been recorded. In acute septicaemia general opinion seemed to be adverse to transfusion, as it usually failed to benefit and might do harm.

Professor Lovell Gulland thought that the length of survival of transfused red cells had been overstated by the American observers. He had not found that there was any great difference in the methods of transfusion so far as the effect on the patient was concerned. He had used polycythaemic patients as donors with great advantage and convenience. In pernicious anaemia he was convinced of the superiority of arsenic over all other forms of treatment, reserving transfusion for those severe cases when time was an all-important factor. Cases with evidence of cardiac failure, chronic kidney mischief, high fever, or severe gastric or hepatic disturbance were not good cases for transfusion. In leukaemia one must distinguish between the acute and chronic forms; in the former he had had no good results; in the latter the only indication for transfusion, in his opinion, was intractable haemorrhage. In aplastic anaemia it was never of any good in the acute form, and sometimes caused severe reactions. He had been occupied for some time in a long study of haemophilia, and would only say that transfusion was found to bring the coagulation curve nearer to the normal than any other method. Professor René Cruchet gave the results of his

experiments in transfusing animal blood to man. After much preliminary work on animals, he had given sheep's blood to man in eight cases, and horse's blood in twelve cases, and in four of them the transfusion had been repeated a second time. The amount of blood given varied from 25 to 80 c.cm. One patient gravely ill with pyaemia had died suddenly after the injection of 2 c.cm. of horse's blood, but apart from this no really severe reaction had been observed. Two of the patients showed no change, the others all appeared to benefit by the transfusion. The transfusion must be made very slowly, particularly at the outset; the donor animal must be absolutely healthy and in a state of muscular rest; the blood must be used immediately after removal from the animal; citrated blood was used; blood diluted with physiological serum was preferable to pure blood. Dr. E. I. Spriggs referred to the practical value of transfusion (1) after haemorrhage from the bowel; (2) as a prophylactic against post-operative shock in malignant disease; (3) in pernicious anaemia. As regards technique, he particularly emphasized the advantage of the air-bag of the sphygmomanometer in place of a tourniquet, the pump of a sphygmomanometer to aid the flow of blood, and sharp needles. Any cutting operation was quite unnecessary. Mr. Geoffrey Keynes reviewed the value of transfusion in surgical practice. The statistics of the London Transfusion Service of the Red Cross Society showed that transfusion was apparently used twice as often in surgical as in medical cases. He dealt especially with its value in cases of gastric and duodenal ulcer; he considered it extremely unlikely that a transfusion dislodged a clot already formed; on the other hand, it might well increase the coagulability of the blood. A series of cases was described in which transfusion and operation had saved otherwise hopeless cases. Dr. Trethowan Rowe spoke of some hopeful results he had had in cases of infective endocarditis. Dr. F. B. Smith (Harrogate) discussed severe reactions and gave details of two cases. Professor Ervarts Graham was enthusiastic over the results of transfusion in well selected cases, and mentioned its possible value in severe burns to counteract the toxæmia. Dr. Robert Platt advocated the use of defibrinated blood rather than citrated blood.

Friday, July 23rd.

#### THE NATURE OF MALIGNANT NEOPLASIA, AND THEIR TREATMENT WITH LEAD.

Owing to Dr. Blair Bell's absence through illness his opening contribution to the symposium on the nature of malignant neoplasia, and the treatment of this disease with lead, was delivered by Professor Adami. In this paper Dr. Blair Bell described the constitution and methods of work of the Liverpool Cancer Research Committee, and concluded with a brief statement of his own views on the nature of malignant neoplasia. There were many factors producing the "precancerous condition"—radiation, heat, trauma, toxæmia, senescence, etc., which reduced the vitality of the cell—a condition which might terminate in recovery, death, or in reversionary development in order that the cell might live. It seemed probable that the metabolic disturbance responsible might be one of oxygen starvation. The ancestral type to which the cell sought to return in the reversionary process was that of the chorionic epithelium: Malignant neoplasia was, therefore, a specific process of dedifferentiation from high specialization towards the most distant ancestral type—the chorionic epithelium. If this were so it would be expected that the chorionic epithelium would be found to resemble the malignant cell in structure, function, chemical composition, and toxicological affinities; an amount of convincing confirmatory evidence in these directions had been obtained, as the later contributions would indicate. Professor W. C. M. Lewis dealt first with the electrical conductivity and permeability of malignant tissue; the former had been shown to be higher in freshly removed cancerous tissue than in normal tissue, and an increased conductivity necessarily meant an increased permeability to such soluble constituents on the part of any membranes or septa in the cells. Of the substances concerned in maintaining permeability or impermeability calcium was important, and appeared to be definitely deficient in malignant tissues, in which case

increased permeability and conductivity were to be expected. Other substances involved were the phosphatides and cholesterol, the two being antagonistic, and alterations in the normal phosphate-cholesterol ratio were highly significant. This ratio was much higher in malignant tissues than in normal tissues, and it was highest of all in chorionic villi. No striking difference had been noted in the pH of the blood or tumour in malignancy. The antitryptic power of the blood was usually increased in cancer patients. Of all the chemical processes usually regarded as of importance for cell life glucolysis was the only one in which striking differences had been found in malignant as compared with normal tissue. Warburg had found that high glucolytic power was a general characteristic of growing tissue, but that appreciable glucolytic power under aerobic conditions was characteristic only of unordered growth. The problem as to the nature of the condition which made excessive glucolysis possible was still unsolved. Professor Lewis concluded with some notes on lead suspensions. Professor Dilling described investigations to determine whether there was any proof that lead salts had unusual powers in retarding normal growth when compared with other metals; they confirmed previous work, and indicated that (1) lead was distinctly more toxic to germ cells and to embryonic tissues than to mature tissues; (2) its adverse influence was more marked on the ovum, and was responsible for temporary sterility and early abortion in females; (3) in non-lethal doses its retarding influence appeared to be in inverse proportion to the age of the animal, and tended to persist; (4) the inhibiting and retarding power was more a characteristic of lead than of any of the other metals tested. He then turned to the untoward effect of lead on human beings, and described experiments which showed that lead acted directly on the intestine, causing first an inhibition, to be followed later by increased tonic contraction. The action on the isolated uterus was essentially similar to that on the intestine. In conclusion, Professor Dilling described two recent tests of Professor Lewis's colloidal lead and of a similar preparation by British colloids, which it was hoped to issue shortly. Professor F. Carter Wood gave a short summary of the changes seen in the tumours in a large series of animal experiments which he had agreed with Professor Blair Bell to undertake at Columbia University. The experiments were made on white rats, and sarcoma and carcinoma were used. In sarcomas the effect of lead was to produce an extensive congestion due to thrombosis and was followed by necrosis, so that only a thin layer of tumour cells was left surrounding a haemorrhagic sac. In a few cases the process went on to complete absorption, but in general recurrence followed. There was necrosis in the liver and extensive lesions in the spleen. These tumours were all very rapidly growing ones, and of a degree of malignancy rarely seen in human disease. Professor E. Glynn gave an account of the histological investigation of the tissues removed after lead injections. His tentative conclusions were: (1) There was evidence that lead had damaged a very small percentage of malignant neoplasms examined; among the changes found there was a greater tendency to necrosis and sometimes to a slowing of the rate of growth. (2) There was no damage to malignant growth which was histologically pathognomonic of lead; it most probably acted by increasing the regressive changes that occurred to some degree in all malignant neoplasms. The tendency to thrombosis in cancer was no greater; in sarcoma it might be greater, but was secondary. (3) The effect on the same type of malignant growth varied greatly in different individuals; the patient's tissues probably played a determining part. Dr. L. Cunningham described the clinical effects of lead in the treatment of malignant disease. Careful blood and urinary analyses were made in all cases. Pain was generally felt at the site of the tumour soon after injection. All types of anaemia had been noted, from severe secondary anaemia to aplastic pernicious anaemia. Great stress was laid on the number of stippled red cells present, and this was used as a guide in prescribing continued dosage; stippling he did not consider as a regenerative change, as no stippling had been found in the marrow of animals injected with lead. The kidneys were often involved early, but recovery was usually rapid when

the lesion was produced by large doses; such doses over a long period seemed to produce more permanent damage. Dr. Cunningham gave the details of the technique of administration and the doses given, and ended with a summary of the results of treatment. Out of 227 cases treated 50 had received benefit; these 50 patients were either living normal lives (9), or the disease had been completely arrested (10), or the disease was believed to be cured and treatment stopped (31). Dr. S. Miller gave the results of his experience in treating 18 cases during the last three months. Most of the cases were inoperable, and most of them had so far improved. He had had no really severe reactions. If the haemoglobin fell below 50 per cent. he gave a blood transfusion, and the progress of blood change was carefully watched by a count of the stippled cells. Mr. Frank Coke also described favourable results during the last three years.

## SECTION OF OBSTETRICS AND GYNAECOLOGY.

*Thursday, July 22nd.*

### INDUCTION OF PREMATURE LABOUR IN THE TREATMENT OF CONTRACTED PELVIS.

THE proceedings of this Section on the second day were opened by Dr. J. Bright Banister, who read a paper on the place of induction of premature labour in the treatment of contracted pelvis. Dr. Banister feared that Caesarean section was being performed more often than was justified; there was more in the treatment of labour with contracted pelvis than the employment of Caesarean section. He was sure that induction of premature labour could be successfully employed in many cases where Caesarean section was now performed. His conclusions were based upon an analysis of 745 cases of induction for contracted pelvis at Queen Charlotte's Hospital, Charing Cross Hospital, and in his own private practice. The risk to the mother of this procedure was very small, there being one death only in the whole series, and that from pulmonary embolism; this gave a maternal mortality of 1.3 per 1,000. There had been 99 foetal deaths, 56 being neo-natal and 43 post-natal. In five of these cases the cause of death was wholly unconnected with the induction of premature labour. It was an enormous advantage to obtain a natural delivery if possible. The foetal deaths in unassisted cases amounted to 8.5 per cent., whereas with forceps delivery the mortality rate was 23.4 per cent.; it was relatively much greater with posterior positions of the vertex. Provided there was no undue delay, the result to the baby was better the later induction was carried out. The method had failed in 24 cases; in five of these embryotomy had to be carried out, and in 8 cases living babies were delivered by Caesarean section. The morbidity rate was no higher than occurred in normal deliveries. Prolapse of the cord had occurred in 12 cases with foetal death in 9 cases, but this might be attributed as much to the contracted pelvis as to the operation. If the true conjugate were calculated to be  $3\frac{1}{4}$  in. or less, induction was contraindicated and the rational treatment was Caesarean section at full term. With a larger pelvis the problem to be solved was the optimum time for the operation. The two main points for consideration were—the relative sizes of the presenting part and the pelvic brim, and the shape of the pelvis. Subsidiary to this was the position of the child's head. Frequent examinations were imperative. Patients should be seen once a week, and the size of the head compared with the pelvis should be estimated each time. In a general way it might be said that a pelvis contracted in all directions indicated an earlier induction than one in which the deformity consisted of flattening. When descent of the head through the pelvic brim became doubtful, he advised examination under an anaesthetic; it would then generally be found that the disproportion was not so marked as had been thought. According to the findings induction should be advised in a fortnight, a week, or immediately. He did not think that patients would be found to object to the frequent examinations, even under anaesthesia, in view of the present-day tendency for prospective mothers to demand ante-natal care and protection from the difficulties of childbirth. The employment of induction

provided evidence of great value as to the capacity of a particular uterus to deliver children in subsequent pregnancies. He urged a wider use of induction in cases of contracted pelvis because it was simple, safe, and unaccompanied by untoward complications.

Dr. Rhoda Adamson said that the question of induction of labour depended on the degree of contraction and on the shape of the pelvis. She had found that among her private patients the commonest form of contraction was the small round pelvis. Among her hospital cases contraction was generally due to flattening caused by infantile rickets. The small flat pelvis was not suitable for any treatment except Caesarean section, as the pelvic outlet would not permit the passage of a viable child. She had had good results in cases of the simple flat pelvis, the patients being allowed to go into labour at term. Some had been prepared for Caesarean section and then delivered themselves spontaneously. It was worth remembering that the child's head tended to resemble in shape and hardness the head of its father. In her view actual measurements were far less important than the relative fit of the presenting head at the inlet. Dr. English (Singapore) had always found that estimation of the relation between the head and the pelvis was of far more value than measurements with a pelvimeter. He advocated giving to any patient who had a difficult confinement a history sheet for the guidance of anyone who might be responsible for the conduct of her future labours. Professor McIlroy did not perform Caesarean section nearly so frequently now as before; one reason was that she never operated until labour had commenced. The estimation of contraction at the pelvic outlet was a far more difficult matter than that of contraction at the brim, and an accurate method of measuring the outlet would be a great advance in obstetrics. She did not advocate induction of premature labour till the thirty-eighth week. An exact estimation of the date of pregnancy was very difficult, but was of the utmost importance from the point of view of ascertaining the right time for inducing labour. Mr. Henry Evers thought that the real difficulty was to identify the border-line case in a primipara. He agreed that the really important point was the fit of the head in the brim. He had investigated 150 cases of primigravidae in which the head was above the brim, and in 12 per cent. it had been necessary to perform Caesarean section. Induction here might have saved some unnecessary sections. The most serious trap was the asymmetrical type of contracted pelvis. Mr. L. C. Rivett said that though a trial labour was an enormous advantage it was nevertheless equally important to examine the multipara, as subsequent children might be appreciably bigger than the first. He agreed that the infantile mortality was much higher when forceps had been employed. Mr. Maslin Jones (Wolverhampton) remarked that the problems of induction assumed a different aspect when no maternity beds were available. He had not found the quinine-castor oil method of much value before term. He thought that induction was an operation which could quite safely be undertaken outside an institution.

Mr. Danby had recently been using for induction a solid oesophageal tube in place of the stomach tube, and out of 20 cases 18 had been successful. In 38 cases in which quinine and castor oil had been used 26 were successful. He never induced before the thirty-sixth week, and he did not concern himself with the size of the diagonal conjugate. Mr. T. H. Richmond (Stoke-on-Trent) spoke in favour of the use of pituitrin at full term to prevent post-maturity occurring. The President agreed that induction of labour was ever so much safer than Caesarean section, and referred to the risk of rupture of the uterus after administration of pituitrin. Induction should not be attempted with a conjugate of  $3\frac{1}{4}$  in. and under. Labour was often difficult when the father and mother were of disproportionate physique. He did not think that any vaginal examination in a pregnant woman should be made before the thirty-sixth week. A recent investigation had shown that induction was frequently performed too early; many women who had required induction of labour for the first child had subsequently natural labours. Dr. Adamson, in her reply, spoke in favour of rectal rather than vaginal examination in pregnant women. Dr. Banister, con-

cluding the discussion, said he thought that obstruction at the outlet was of very rare occurrence. He outlined the methods he usually adopted, and mentioned his preference for Kraus gum-elastic bougies. Since the introduction of the 10 per cent. solution of pituitrin he had used this successfully without any ill effects.

Friday, July 23rd.

#### CAUSES AND TREATMENT OF UTERINE HAEMORRHAGE.

At the final meeting of this Section, Mr. Beckwith Whitehouse read a paper on the causes and treatment of uterine haemorrhage without gross physical signs, and mentioned that for five thousand years this subject had been prominent in medical and lay literature. During the past hundred years conflicting theories had complicated the points at issue, but in the last few years more solid knowledge was being based upon the truths of physiological and pathological research. A correct conception regarding menstruation was the key to the proper understanding of the phenomena associated with pathological haemorrhage. In 1914 he had expressed the opinion that at each menstrual function there was a definite shedding of portions of the superficial endometrium and that the menstrual discharge consisted of the autolysed products of the result of this necrosis. The only modification which he thought desirable in the light of recent work was that in most cases autolysis of the clot and tissue commenced while the separating endometrium was actually in anatomic contact with the deeper layers, and while the extravasated blood was intimately associated with the epithelial debris. It was the exception for no clots to be passed at some time during the menstrual function, though these might only be minute coagula and not recognizable as clots. Menstruation apparently corresponded to the death of the unfertilized ovum and was synchronous with the commencing retrogression of the corpus luteum; the ducts of decidual necrosis were then cast off as the menstrual discharge, for which he suggested the name of "menstrual lochia." The cause of the periodicity of the menstrual function was associated with the high degree of specialization of the human species. The human sexual instinct was independent of the uterus and ovaries, as was shown by its development before puberty and its persistence after the natural or artificial menopause. It was probably the thyroid gland which initiated the maturation and rupture of the first ovarian follicle, and was therefore responsible for the first menstruation. All available knowledge pointed to the extreme complexity of the sexual cycle. In regard to the uterine secretions, though in the human species absorption from the vagina was possible, it was unlikely that they had any great part in the production of sex instinct. When fertilization did not occur he thought that the uterine secretion was responsible for removing by autolysis the necrosed menstrual decidua and coagula. Mr. Whitehouse reviewed the data obtained from an analysis of 200 cases of functional uterine haemorrhage with no obvious physical signs, and classified these cases into four groups: (1) Periods too frequent, or epimenorrhoea. (2) Periods too prolonged, or menorrhagia. (3) Excessive loss of blood, or too high pressure: such ovaries were hyperplastic and often polycystic; they usually contained much retrogressive luteum tissue. This type was common at the beginning and the end of sexual life. Curettage was, of course, useless, but treatment directed to the thyroid and pituitary glands would probably be beneficial. Menorrhagia was, however, believed, analogous to an incomplete fertile uterine abortion. Chronic endometritis predisposed to the condition, but was not the only cause. He suspected that the corpus luteum was intimately associated with this type of haemorrhage. Simple curetting frequently cured this condition: type of post-partum haemorrhage, and was essentially due to "uterine insufficiency." It might be the result of many diverse factors affecting both metrium and endometrium, or a temporary developmental attribute of adolescence. Senility was frequently associated with uterine insufficiency owing to atrophy and fibrosis of the

uterine wall. Menorrhagia was much more serious than menostaxis, and a severe degree of anaemia might result. At puberty curetting might be sufficient; in other cases it should be combined with radiation of the thyroid. At the menopause the intrauterine application of radium was the most useful measure available as it destroyed the tissue which aborted. Metrostaxis included all haemorrhages independent of the menstrual cycle. Haemorrhage was frequently severe, was bright red, and large clots were not unusually present. There was usually present a diffuse hyperplasia of the endometrium, but it might be localized as in the case of the simple adenomatous polypus of the endometrium. A polypus might in fact be but a local safety-valve, some deeper underlying unknown cause being present. The sympathetic vasomotor centres in the tractus intermedio-lateralis of the medulla were probably intimately associated with these haemorrhages. Professor Fletcher Shaw said that until recent years they had always looked for the cause of haemorrhage in the uterine body or the endometrium: now they had to remember the disorders of function associated either with uterine or endocrine changes. He pleaded for a standardized terminology on the lines suggested by Mr. Beckwith Whitehouse. Mr. W. W. King suggested the abolition of the term "endometritis." Chronic subinvolution was the cause underlying very many cases of excessive loss. He discussed the use of luteum and thyroid extracts, haemoplastin serum, cotarnin, and radium in treatment. The President agreed with the necessity for a new and standardized terminology. He spoke very favourably of radium therapy, and much preferred this to x-ray treatment, as in using radium dilatation and curetting would naturally be performed and the chance of missing a possibly malignant condition be much diminished.

#### SECTION OF NEUROLOGY AND PSYCHOLOGY.

Thursday, July 22nd.

#### MANIC-DEPRESSIVE PSYCHOSIS.

On the second day of the meeting in the above Section Dr. E. Mapother opened a discussion on manic-depressive psychosis. After introductory remarks Dr. Mapother said that the range of the term "manic-depressive psychosis" was largely a matter of convention, that there was no constant or specific cause of the condition, and no physical modifications recognizable during life or after death. Under the heading of manic-depressive psychosis were included cases of functional mental disorder which showed as their predominant feature one of a contrasting pair of anomalous types of reaction: (1) melancholic or depressive reaction, and (2) manic reaction. The two syndromes were often seen at different times in the same patient, and were merely deviations from the normal in different directions. It had been emphasized that cases of manic-depressive type did not tend to dementia even after a number of attacks; in pure form during the early stage did sometimes end as typical dementia praecox. Morbid fear with insight had been picked out and labelled "anxiety neurosis," but the condition appeared to merge into other types of depression. As regards pathology, they were still uncertain as to whether the primary change was in the central nervous system or elsewhere. There was gradually accumulating evidence that certain physical changes were primary and essential. Among these were: histological abnormalities in the cortex cerebri, pituitary gland, and gonads, anomalous blood sugar curves, haemoclastic crises, changes in the gastric secretion, etc. Such changes, however, seemed common to dementia praecox and manic-depressive psychosis, the difference being merely one of intensity.

The President (Dr. Farquhar Buzzard) dealt with certain practical aspects of the disease. He considered that in mild or moderate form the disorder was more common than generally supposed, but was not recognized. The distinction between mild manic-depressive psychosis and anxiety neurosis was one of fundamental importance, and he disagreed with Dr. Mapother on the question of the latter being regarded as merely a subdivision of manic-depressive psychosis. In the two conditions the prognosis

and treatment were entirely different. In distinguishing them, Dr. Buzzard emphasized the need for a careful and detailed history. Dr. T. A. Ross joined issue with the opener on the question of the identification of psychoneuroses with manic-depressive psychosis. In his opinion the fundamental difference lay in the mental state; by careful attention to this factor the differential diagnosis could be made. One essential difference was that of remorse; the psychoneurotic blamed anything or anybody but himself for his malady, and if remorse was present the patient certainly belonged to the manic-depressive group. Dr. R. D. Gillespie expressed disagreement with Dr. Mapother's definition of manic-depressive psychosis, and considered that the number of cases terminating in dementia was very small indeed. He also disagreed with the proposal to classify anxiety neuroses with manic-depressive psychosis, and reminded the opener that the histological changes in the cerebral cortex and gonads in the latter disorder, to which reference had been made, still awaited confirmation. Dr. R. H. Cole stated that all individuals were liable to manic or depressive reactions of a mild type, and that manic-depressive psychosis was merely an exaggeration of this almost physiological state. He was doubtful, however, if there was sufficient evidence to warrant the statement that a psychoneurosis could become a definite psychosis. Dr. R. G. Gordon said that much confusion existed with regard to manic-depressive psychosis, as they were dealing purely with symptoms. He believed that manic-depressive psychosis and schizophrenia each related to entirely different types of personality. The real advance in psychiatry would probably be made in the differentiation of these personality types. Dr. Mapother then replied to the various criticisms offered.

Friday, July 23rd.

#### PITUITARY DISORDERS.

On the third day of meeting a discussion on disorders of the pituitary gland was opened by Dr. Gordon Holmes (London). He observed that in recent years the physiology of the pituitary gland had become a very vexed question, as disturbances in the floor of the fourth ventricle, without involvement of the pituitary, had been shown to give rise to typical dyspituitary syndromes. Dr. Holmes then gave a general review of the different types of pituitary disorder, including acromegaly, gigantism, and Fröhlich's syndrome, illustrating his remarks with lantern slides of photographed cases. Among the disturbances of growth seen in acromegaly a less well known occurrence was considerable enlargement of the colon. The variations in carbohydrate metabolism and blood sugar curves seen in different forms of pituitary disorder were then described. Increased carbohydrate tolerance was usual in hypopituitarism, and diminished tolerance, and often glycosuria, in acromegaly; it had been found that such glycosuria could be controlled by insulin. The effects of local pressure on neighbouring nervous structures by an enlarged pituitary were next dealt with, and also the various modifications of visual field disturbance resulting from interference with the optic nerves and chiasma. Finally, Dr. Holmes discussed the question of treatment. In his experience endocrine therapy had proved disappointing, while x-ray treatment often gave results as good as those produced by surgical measures.

Mr. Norman Dott discussed the surgical aspect of pituitary disorders. It was necessary to distinguish between tumours or cysts arising within the sella turcica (pituitary tumours proper) and those arising above the sella turcica (suprapituitary tumours), as the surgical approach in each case was entirely different. In suprapituitary tumours the transfrontal method was indicated, while in his experience the trans-sphenoidal route, as advocated by Harvey Cushing, was the operation of choice. X-ray examination was of prime importance in the differential diagnosis. In pituitary tumours enlargement of the sella was often found, while in suprapituitary lesions the sella was not enlarged, but might be unduly flattened. He considered that operation should be urged when the visual fields were progressively diminishing. Mr. M. L. Hine dealt with the subject from the ophthalmological standpoint, and emphasized the need for carefully taking the visual fields with test objects.

Dr. W. J. Adie (London) discussed the relation of the pituitary body to the vegetative nervous centres situated in the hypothalamic region. In his opinion there was a close physiological relationship between the two, and similar symptoms might arise from disease of these nervous centres as from pituitary lesions. He illustrated his remarks with references to certain cases of encephalitis lethargica in which this region was involved. Dr. Gardiner-Hill described investigations on disturbances of growth, obesity, and carbohydrate metabolism in children. There was a high proportion of cases in which the syndromes of obesity and overgrowth were combined and continued up till puberty. Mr. Geoffrey Jefferson described the surgical measures adopted to deal with pituitary tumours. It was scarcely to be hoped to remove such tumours entirely; operation should be undertaken mainly for the relief of pressure, to relieve visual defects, and to prevent blindness. Mr. Jefferson then dealt in detail with the trans-sphenoidal method of approach. Dr. Eaves referred to three cases of dyspituitarism, with post-mortem examinations, which she had investigated. In one case of hypopituitarism the pituitary was small and fibrosed; in a second case of infantilism, with polyuria, both the anterior and posterior lobes of the pituitary were involved; and in the third case, one of post-encephalitic lethargica, the anterior lobe only was fibrosed. She also discussed the effect of insulin on the pituitary gland. Dr. C. G. Imrie described a case of polyuria following encephalitis lethargica in which the urinary secretion was controlled by insulin. He also discussed the influence of pituitrin injections on the blood sugar curve; the effect of 1/2 c.cm. of pituitrin on increasing the rise of the curve was greater than that of 50 grams of glucose.

#### SECTION OF LARYNGOLOGY AND OTOTOLOGY.

Thursday, July 22nd.

#### AFTER-TREATMENT AND RESULTS OF THE MASTOID OPERATION.

At the second session of the Section of Laryngology and Otology, with Mr. Norman Patterson, vice-president of the Section, in the chair, a discussion on the after-treatment and results of the radical and the simple mastoid operations was opened by Mr. G. J. Jenkins (London). He said that, as regards the operation for acute mastoiditis, whatever method of treatment was adopted, the primary object should be the prevention of an extension of the septic process, but that it was important to consider how the ear might be left as near normal as possible. By the Schwartze operation the damaged tissues behind the aditus were removed, and at the same time the surgeon made sure that the tympanic cavity was sufficiently drained either by spontaneous opening or by paracentesis. It was also important to deal with all systems of cells in the mastoid, including those which might not appear obviously infected. Since the war many aural surgeons had tried primary closure of the mastoid wound after the Schwartze operation. Mr. Jenkins had come to the conclusion that there were certain extensive irregular cavities where the soft tissues could not be brought into intimate contact with the deep bony parts, and that in such circumstances primary suture was not likely to succeed and was unsafe. He felt that the risk to the patient was too great and the result not always satisfactory. He was in favour of after-treatment by the maintenance of an open wound, using the whole or part of the mastoid incision, or by making another drainage wound into the meatus and closing the original wound. In his experience, even in selected cases, drainage from the lower part of the mastoid wound was more effective than meatal drainage; and the healing was as rapid and was more under control. When there was a small well defined cavity, such as a simple gutter in the anterior part of the mastoid, it was his custom to stitch up the upper part of the incision and to drain from the lower part of the wound. The process of healing was commonly uneventful, and the resulting scar was not in any way objectionable. If there was any serious delay in healing, or if there was a tendency for the epithelium to dip into the wound, Mr. Jenkins strongly advocated secondary suture, which rarely failed if carefully done.

Mr. J. S. Fraser (Edinburgh) said that the first and most important object of the radical and modified radical mastoid operations was to place the patient in a position of safety as regards life—namely, to free him or her from the possibility of an intracranial complication. In twenty years he had known only one case in which an intracranial complication occurred in a patient who had had a radical mastoid operation, but he had known several in which a patient suffering from chronic middle-ear suppuration, without any acute symptoms, had had his name entered on the hospital waiting list for operation, and had had to be taken in as an urgent case of intracranial complication before his turn. With regard to the technique of the operation, he had found that with a primary skin graft the operation cavity healed much more quickly, that the outline of the inner wall was preserved in almost all cases, that the first dressing was nearly painless and subsequent dressings unnecessary, that the duration of the patient's stay in hospital was greatly reduced, that a dry and satisfactory cavity resulted in a larger percentage of cases than with other methods, and, finally, that as regards the hearing power the results were better than when the skin graft was omitted. He applied the graft to the bony surface at the time of operation, by means of a long string of iodoform worsted which was packed into the cavity. The wound was dressed on the fourth or fifth day, the silkworm gut sutures, including that retaining the mental flap, were taken out, and the iodoform packing was removed. As a rule there was no bleeding and no necessity to clean out the cavity. In most cases he put in fresh iodoform worsted packing, and applied gauze wool and a trefoil bandage for another two days. At the end of that time all dressings were omitted in the daytime, a piece of iodoform gauze being inserted into the meatus at night to avoid staining the pillow, and the meatus was left open. The patient was, as a rule, able to leave the hospital in fourteen days, and printed instructions were given to him regarding keeping the cavity clean by syringing. Mr. Fraser concluded by giving detailed statistics of his results in 628 cases of the radical mastoid operation; the skin graft had proved entirely unsuccessful in only 11 out of 377 cases in which it was employed. The discussion was continued by Professor von Neumann, who proclaimed himself conservative as regards the radical operation, but radical as regards the conservative operation, and gave a demonstration of many instructive lantern slides and specimens.

Friday, July 23rd.

#### RESECTION OF THE NASAL SEPTUM.

At the third session of the Section of Laryngology and Otology, with Dr. Brown Kelly, President of the Section, in the chair, a number of papers were read. Dr. W. Jobson Horne, speaking on the sorrows of the septum, said that in his opinion the younger generation of rhinologists pinned their faith far too implicitly to the operation of submucous resection of the nasal septum, with the idea of remedying all sorts of ailments of the nose. He considered that that operation was far too frequently done, and that its results were not at all so good as they ought to be. In his opinion the old-fashioned Moure's operation was often a better procedure. Much of the attention devoted to the nasal septum ought to be turned towards the turbinates and the nasal sinuses instead.

#### PHARYNGEAL AND OESOPHAGEAL DIVERTICULA.

Dr. William Hill, in a paper on pharyngeal and oesophageal diverticula, said that there was probably no group of lesions in the description of which so much inaccuracy had been perpetuated as in the diverticula of the pharynx and of the oesophagus. Dr. Hill subdivided diverticula which were pharyngeal in origin into congenital lateral post-faucial diverticula, congenital centrally placed anterior diverticula, and deep pharyngeal pressure diverticula or pouches. Those which were oesophageal in origin he separated into traction diverticula situated more or less at the level of the hilus of the lung, the traction-pulsion diverticula of Starck, Leugart's post-bronchial lodge pulsion diverticula, and epiphrenic pulsion diverticula. He then proceeded to give detailed descriptions of

the various types, described the methods of their formation, and detailed their operative treatment. His paper was illustrated by a large number of excellent lantern slides.

#### RETROPHARYNGEAL ABSCESS IN CHILDHOOD.

Dr. Douglas Guthrie read a paper on acute retropharyngeal abscess in childhood. He said that two varieties of retropharyngeal abscess were distinguished in most textbooks, but that the spinal variety of tuberculous origin was relatively rare. The acute variety of abscess, of lymphatic origin, was, on the other hand, fairly common, but, insidious in origin and often presenting no characteristic sign or symptom, it frequently escaped diagnosis or was discovered only at *post-mortem* examination. The condition escaped recognition perhaps more frequently than any other acute disease in childhood, and if untreated almost invariably ended in death. On the other hand, when a retropharyngeal abscess was recognized and opened, the prognosis was good and the patient recovered rapidly. The most characteristic symptom, almost invariably present, was difficulty of breathing, but the diagnosis was merely a matter of conjecture until the throat was examined, when a swelling could be seen on the posterior pharyngeal wall, to one side of the middle line. Digital examination was the most certain diagnostic test, but should not be practised unless preparations were made to open the abscess at once, if necessary; this should be done without any anaesthetic and from the mouth.

#### SECTION OF PATHOLOGY AND BACTERIOLOGY.

Friday, July 23rd.

#### LEUKAEMIA AND ALLIED CONDITIONS.

PROFESSOR G. LOVELL GULLAND, opening a discussion on leukaemia, gave reasons for his view that this condition was of neoplastic origin—namely, a sarcomatosis of the leucocytes. It might be due possibly to a disturbance of the factor regulating the number of leucocytes. He considered briefly the phylogeny of the white cells and pointed out that the leukaemic process might affect any or all stages of development. He was sceptical of the existence of a really acute lymphocytic leukaemia, since most of the descriptions belonged to a time before the myeloblast was recognized as a separate entity. With regard to "mixed" forms it was evident that almost every case was "mixed" at some stage. Patients did not die of the leucocytic excess but of anaemia. Chronic cases might go on for years with slight anaemia, while in acute leukaemia the red count might be lowered by a million every few days. Probably this depended on the rate at which the marrow was filled by proliferating leucocytes. In cases of acute myeloblastic leukaemia he had found the marrow pure white to the naked eye and consisting of nothing but myeloblasts. Haemorrhage increased the anaemia and was badly borne because there was no reserve power of regeneration in the bone marrow. The speaker then discussed the differential diagnosis of leukaemia and gave an account of two cases illustrating the difficulty of distinguishing the disease in the aleukaemic phase.

In the unavoidable absence of Dr. S. W. Paterson, Dr. Anderson (Melbourne, Australia) read his paper. He reviewed a series of cases of disease of blood-forming organs. From the clinical aspect he grouped them under tumour of glands, tumour of spleen, or tumour of mediastinum; he discussed the leading features of each group. Professor J. Sholto Douglas raised the question of the value of the oxidase reaction. He commented on the fact that cases of leukaemia often appeared in groups, which suggested that it might be regarded as an epidemic disease. Dr. Robert Donaldson said that the textbook classification of leukaemia was too rigid. He disagreed with Professor Gulland as to the sarcomatous origin of leukaemia. There was still complete ignorance about the governing factor of the disease. Examination of cells of the blood and marrow did not help as there were as many classifications as observers.

#### STUDY OF THE LIVING TISSUE CELL.

Dr. T. S. P. Strangeways and Dr. R. G. Canti contributed a paper on the study of the living tissue cell by

dark-ground illumination. Dr. Strangeways entered into a discussion of cell biology and the mechanism of growth and reproduction, in which profound scientific investigation reached the confines of philosophy. Dr. Canti described the method of making tissue cultures and gave an account of cell division as observed under dark-ground illumination.

Dr. Strangeways and Dr. Canti gave a demonstration of living tissue under dark-ground illumination, showing the structure of living cells and intracellular activity. The technique of the method has been described by Dr. Canti and published in the *JOURNAL* of July 24th (p. 155). The outlines of the flattened vegetative cells showed clearly. The cell structures—that is, nucleus, nucleoli, mitochondria, fat globules, and metabolites—were easily visible and their movements fascinating to watch.

## SECTIONS OF DISEASES OF CHILDREN AND ORTHOPAEDICS.

Thursday, July 22nd.

### SPASTIC PARALYSIS.

On the second day of the meeting a discussion by these two Sections on spastic paralysis in children was opened by Dr. W. J. Adie, who defined its scope and said that nothing material had been added to the accurate clinical description of the condition given by W. J. Little more than eighty years ago. While meningeal haemorrhage must be struck out as a cause of any infantile spastic state, birth injury, which might occur even in an apparently normal labour, was most often present, as had been shown by the important researches of Schwartz of Frankfurt and his assistants. The speaker was much struck by the resemblance between the syndrome of Little's disease and the condition seen in men wounded in the region of the superior longitudinal sinus in the war. He gave reasons for rejecting the view that primary neuronc degeneration was the cause of Little's disease, which, it should be noted, was not familial or progressive as such degenerations generally were. Great defect of the powers of speech might accompany a normal or more than average intellect. Epilepsy, athetosis, and chorea were generally contraindications to surgical treatment. After describing various forms of familial diplegias and spastic affections, the speaker briefly referred to the alleged sympathetic innervation of striated muscle; he thought that the evidence was against this view, for complete ablation of the sympathetic had no effect on decerebrate rigidity. Mr. Blundell Bankart said that the condition was most often due to a defect of the upper motor neurone, and was an exaggeration of the postural reflex. Its treatment was operative—on the muscles and tendons when structural shortening had supervened, but in all cases also on the peripheral motor nerves. Foerster's operation of posterior root section was now universally abandoned. The operation of cutting the sympathetic rami, which was based on the work of Hunter and Royle, had proved ineffective in his and other surgeons' hands. The object of all operations was to diminish the effective action of the preponderating group of muscles, either by lengthening them or by destroying part of it. The speaker thought that Stöffel's operations had advantages over others; they consisted in excising the nerve tracts to the overacting muscles, usually before they left the main trunk. Prolonged after-treatment and the use of splints were unnecessary. Dr. John Beattie showed a number of motion pictures to substantiate the contention of Hunter and Royle that muscle tone was influenced by the sympathetic nerves. These very clearly demonstrated the effects of operations on the central nervous system of goats, sea-gulls, and domestic fowls. In the decerebrate goat the hind limb on the side on which the sympathetic rami had been cut was flaccid. Mr. S. W. Daw agreed with Mr. Bankart as to the great superiority of operations on nerves over those on tendons in suitable cases. For secondary contracture of the triceps cruris he preferred incision of the fascia of the soleus and forcible stretching to tendon lengthening. In the upper limb operation was less necessary and less successful in its functional result. Tendon and tendon transfer as for

posterior interosseous nerve palsy were useful, however. The value of the cosmetic effect of such procedures was worth consideration. Mr. Tyrrell Gray said that a selection of cases was necessary, and the patient's desire to walk was a great factor in producing useful results. He preferred the extra peritoneal operation on the obturator nerves. Dr. F. M. R. Walsho maintained that the histological evidence certainly did not establish the sympathetic innervation of voluntary muscle, and consequently he disapproved of cutting the sympathetic rami for spasm. Dr. E. W. Neill Hobhouse thought it was possible to prevent severe spasm in the early stages and prevent need for operation. He emphatically condemned faradization, which the relations and friends and parents were too fond of using on their own responsibility. Dr. W. F. Menzies emphasized the importance of education before spasm became extreme, as there was no rigidity or spasticity at first. Mr. Rocyn-Jones spoke of the beneficial mental effect of physical improvement after operation. In treating adductor spasm by Stöffel's operation he always excised the tendon of the adductor longus. Operations on the arm were disappointing except for their cosmetic effect. Mr. Alan Todd had found bimanual exercises useful when the condition involved the upper extremity. He relied much on a keen mother and a wheelbarrow. Dr. H. J. Capou said that treatment begun at the age of 2 years was too late. It should begin at 1 or 2 days, before diplegia developed. Oedema, congestion, laceration, and haemorrhage required lumbar puncture to drain away the blood, etc.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### GANGRENE OF FINGERS DUE TO SUBCLAVIAN COMPRESSION.

DESCENT of the shoulder during growth or through muscular weakness may occasionally cause compression of the lowest trunk of the brachial plexus by a normal first thoracic rib. T. Murphy, Morley, Stiles, Stopford, and Wheeler have each described instances of this condition. The following case illustrates the fact that the subclavian artery may suffer similar compression at the thoracic inlet.

A man, aged about 50, was admitted to Kasr el Aini Hospital, Cairo, with a useless left upper limb and a dry gangrene affecting the two distal phalanges of the index, middle, and ring fingers of his left hand. He had a flaccid paralysis of the majority of the muscles of the left arm, forearm, and hand, but there was some contracture of the digital extensors which caused the fingers to curve slightly in a dorsal direction. The deltoid was curved and the humeral head had sunk towards the subclavation which could at once be reduced by supporting the elbow, with the same sensation of "telescopic" movement that is found in a congenital luxation of the hip.

The monoplegia had appeared suddenly during sleep a month before admission to hospital, the patient waking to find his limb useless. He stated that fever had accompanied the paralysis and that the gangrene had gradually followed it. There was no sensory loss in the left upper limb; the skin adjoining the gangrenous areas was hyperaesthetic. A very lively left supinator jerk was present, and was accompanied by a very slight increase of the left triceps jerk.

In view of the absence of sensory loss it was difficult to connect the gangrene directly with disease of the nervous system. An examination of the left radial artery at the wrist showed that while its pulsation was distinctly felt when the subclavation was reduced by supporting the elbow, it disappeared completely when the support was removed and the limb hung vertical.

It seemed at first sight that the axillary artery might be suffering compression by the slightly displaced head of the humerus, but after abducting the arm to a right angle the radial pulse reappeared, in spite of the fact that the head bulged further into the axilla. Radiography revealed no cervical rib or other abnormality, and we concluded that the stoppage of the pulse was due to compression of the left subclavian artery at the thoracic inlet.

Raising the limb relieved the compression, but there was a latent period of some thirty seconds before the pulse returned; due, no doubt, to a persistence of the *stupor arterielle* produced by mechanical stimulation of the outer arterial coat. It was

Stopford, J. S., and Telford, E. D.: *Brit. Journ. Surg.*, xii, p. 168.  
Wheeler, W. I. de C.: *Dublin Journ. Med. Science*, April, 1926, p. 65.

impossible to obtain any shadow of the subclavian or axillary arteries in a radiogram.

A series of sphygmograms gave objective confirmation of what had been found by feeling the radial pulse of the affected side. When the elbow was supported a series of well marked percussion waves were seen on the tracing, while when the arm hung by the patient's side the sphygmogram showed an unbroken straight line.

The distribution of the gangrene in the distal phalanges of the index, middle, and ring fingers is explained by the fact that these parts of the hand are furthest from the heart, and for this reason blood failed to reach them when the subclavian artery was compressed at the thoracic inlet.

ARNOLD K. HENRY,  
Professor of Clinical Surgery, Royal  
School of Medicine, Cairo.

AHMED HANDOUSA,  
Resident Surgical Registrar, Kasr el  
Aini Hospital, Cairo

### GENERALIZED TUBERCULOUS PERITONITIS: ACUTE OBSTRUCTION: OPERATION: RECOVERY.

CASES like that here recorded are sufficiently rare to be of interest.

On May 6th last I was called to see a woman, aged 70, who complained of abdominal pain and vomiting. She gave a history of good health except for occasional slight attacks of a similar kind during the past two or three years. She had been up and about until the previous day, and the bowels had opened slightly on each of the two previous days. The temperature was normal, and the pulse 84; the tongue was rather coated. The patient was of spare build and had a lower abdomen with so much mass was felt; rectal examination elicited over the abdomen was dry and but no obvious thing abnormal. No physical signs were found in the chest. Aperients were prescribed, followed later by enemas and colon irrigations; there was practically no result, but the general condition remained good until May 11th, when faecal vomiting occurred. She was then urged to go into hospital for operation, but refused until May 15th, when she was admitted to the County Hospital, Haverford-west. Mr. R. C. B. Macrae operated. The abdomen was opened through a right paramedian incision and an obstruction of the small gut was found about 18 inches from the caecum; this was caused by a band which stretched from a loop of gut to a tuberculous gland in the mesentery; a piece of small gut was also adherent to the mesentery and kinked. Further up a second complete obstruction was found, due to a smaller band stretching from omentum to mesentery, the intestine above being acutely distended. Enlarged glands were present throughout the mesentery, some calcareous and some soft, and small tuberculous nodules were scattered throughout the peritoneal cavity. There was a small quantity of fluid in the pelvis.

The bands were divided and the adherent gut freed; the abdomen was closed without drainage. The patient made an uneventful recovery.

## Reports of Societies.

### RHEUMATOID ARTHRITIS.

A MEETING of the Medico-Chirurgical Society of Edinburgh was held in the Hall of the Scottish headquarters of the British Medical Association on July 7th, the President, Professor RUSSELL, in the chair, when a discussion on rheumatoid arthritis, initiated by Professor Ralph Stockman (Glasgow) and Dr. G. L. Kerr Pringle (Harrogate), was held.

Professor STOCKMAN referred to the varieties in nomenclature associated with this disease. Owing to the fact that the condition resulted from the malign activities of a number of different organisms the clinical designation "rheumatoid arthritis" was satisfactory for the present. Many suggestions regarding the etiology of the condition had been put forward through the ages, but there could be little doubt that it was a germ disease. The probability that there were several different organisms responsible was strengthened by consideration of the different clinical courses noted in the cases met with. In some cases there was a slow, insidious onset with implication of the small joints and gradual implication of the larger joints, perhaps extending over several years. Other cases began as acute arthritis of one of the larger joints with high temperature, rapid pulse, and great constitutional disturbance.

Again, enlargement of the spleen and lymphatic glands might be found, indicating a general blood infection. Ultimately all cases took on a definite chronic course and tended to go from bad to worse. It was important to realize that rheumatoid arthritis was not merely an arthritis but a general disease of which the point of attack was the white fibrous tissue—the connective tissue—of the locomotory system of the whole body. The primary and essential pathology was a fibrositis with swelling and proliferation of white fibrous tissues locally. A perineuritis was set up in the small nerves in the inflamed tissue, and so pains, stiffness, and a fatigued feeling were produced outside the joints. In some cases there was more tendency to attack and erode the cartilage and bone. The sequels of all this included the well known symptoms—the muscular dystrophies, deformities, and contractures. The origin of the disease in any one case might be difficult, and was sometimes impossible, to define certainly. Professor Stockman had seen cases in association with psoriasis, general dermatitis, and lupus erythematosus; rheumatoid arthritis also followed chronic tonsillitis and many other local septic conditions. Treatment resolved itself into two principal endeavours: (1) to combat the infection and bring it to an end, and (2) to remove the fibrositis throughout the body and correct any contractures of muscles and joints. General tonic measures and local application of heat in various forms, baths and spa treatment, had been used from remote times; these, however, had little effect on the general course of the disease. Vaccines from different strains of streptococci and staphylococci had proved of no specific value in Professor Stockman's experience, but during the past five years he had used protein shock or non-specific protein therapy. The benefit appeared to depend on the sharp febrile reaction which followed the injection. Professor Stockman tried various proteins in rheumatoid cases, but now almost confined himself to the typhoid bacillus as the most satisfactory. Beginning with a dose of 100 million intravenously, it was repeated every six days until six injections had been given, the dose being gradually increased to 200 or 250 million. The reaction started within an hour with a rigor and rise of temperature to 103°-105° with nausea, headache, and possibly vomiting. A profuse perspiration was followed by a return to a normal temperature. There was a very marked polymorphonuclear leucocytosis. The reaction lasted for six to twelve hours. There was also a focal reaction, the affected areas becoming painful, slightly swollen, and tender. This passed off, and next day the patient felt better. In about 60 per cent. of upwards of 250 unselected cases which Professor Stockman had treated the infection was brought to an end. The treatment should be commenced early in the disease. The speaker finally referred to the formidable and tedious task of treating the contractures of muscles and joints.

Dr. G. L. KERR PRINGLE referred to the importance of soil and diathesis in addition to infective foci in the production of the disease. He said that the commencement and cessation of menstruation were associated with the disease, and pregnancy had long been considered a cause. He referred to the biochemical investigations at the Royal Bath Hospital, where it was found that the glucose tolerance was lowered in most cases of proliferative arthritis, and that when a septic focus was removed the tolerance became more normal. These patients improved on a low carbohydrate diet, and the basal metabolism did not appear to be altered in them. With regard to treatment, Dr. Pringle said that infective foci should be removed and hydrochloric acid given if there was achlorhydria. In young women with an abnormal menstrual history thyroid extract in small doses with increasing doses of the French tincture of iodine and a low carbohydrate diet should be given, and lavage where there was intestinal stasis. The speaker referred to the local production of hyperaemia by various agents followed by massage. Surgical measures should not be undertaken when there was active disease, and when operation was considered a low glucose tolerance should be obtained. Vaccines sometimes gave excellent results, and in other cases were very disappointing.

## Rebelsus.

### THE DEBT TO OUR TEACHERS.

THE appearance of the fourth edition<sup>1</sup> of Professor E. H. Starling's *Principles of Human Physiology* is a happy reminder of how much we owe to our great teachers. It has been remarked that the progress of a science may be written in the history of a few compelling ideas, from which have sprung schools of thought that have constrained the studies of a generation. Whence derives such power? It comes, surely, from that quality of genius to invest an idea, not alone with the objective evidences of truth, but with that contagious personal enthusiasm to which the human mind cannot deny response. Science is more than logic and stubborn facts, and they who can put breath into the dead bones are our masters, for they make our science for us.

British physiology has been fortunate in her teachers, and Professor Starling must take high place in this good company. As the title indicates, the book is offered, in particular, to the great family of medical students, but the reader is not allowed to forget that human physiology is but a part of our conception of the behaviour of living matter in whatever form it may manifest itself, and that the problem of life is one whole, whether we observe it in the reactions of amoeba or in the activities of man.

Only five years ago the third edition of this textbook appeared, yet the progress in many fields in the intervening years has been such as to persuade the author that further revision was now demanded. It is not the province of a general textbook to have the last word in all the branches which it covers; it is better that new facts should find their level in the general configuration of knowledge before they take their place in the standard works, for we cannot maintain perspective if we crowd the foreground with ill-focused detail. Professor Starling has made extensive but conservative revision of a sort directed to the simplification of the main theses. Intriguing observations find no place if they do not contribute to the balance of the whole composition. The bulk of the book has been appreciably reduced by the removal of much chemical detail which may now be found in the many available biochemical textbooks, and by some modifications in type. Amongst the subjects which have been considerably amended may be mentioned those on muscular activity, the coronary and capillary circulations, conditioned reflexes, respiration, secretion, and the metabolism of carbohydrate. The chapter on the sense organs has again been contributed by Dr. H. Hartridge, and this departure from the personal character of the book seems justified by the special nature of this subject.

Whilst the continued growth and specialization of knowledge make it increasingly evident that the teaching of physiology, which takes toll of all the physical sciences, can only be adequately met by the co-operation of experts in their several fields summarizing in monograph form the progress in those fields, nevertheless the comprehensive textbook from one pen will remain the foundation of education. Here only will the instinct for the subject be formed. But with the extension of knowledge the task of the author of such a book becomes the greater. Few there are that have the courage to shoulder it, and of these not all are happy in their burden. In the pages of "Starling" the student will find no hint of laboured weariness.

### CARBOHYDRATE METABOLISM AND THE PANCREATIC HORMONE.

FROM Toronto and from Paris have arrived two important monographs upon the role of the pancreas in carbohydrate metabolism. The first betrays its authority in the name of its author, Professor J. J. R. MACLEOD, who now joins the select group of contributors to that excellent series of *Monographs on Physiology* which is edited by Professor

<sup>1</sup> *Principles of Human Physiology*. By Ernest H. Starling, C.M.G., F.R.S., M.D., Sc.D., F.R.C.P. The chapter on the sense organs edited by H. Hartridge, M.A., M.B.Cantab. Fourth edition. London: J. and A. Churchill. 1926. (Roy. 8vo, pp. xiii + 1074; 569 figures. 25s. net.)

E. H. Starling. The title which Professor Macleod has chosen—*Carbohydrate Metabolism and Insulin*—aptly states his case. The pancreatic hormone interests him supremely as a new weapon in the armoury of the experimentalist for the assault upon the mysterious recesses of carbohydrate metabolism. The story, therefore, opens with the discovery of insulin in the Toronto laboratory and its effects upon depancreatized dogs. There follows an adequate discussion of those physiological criteria—such as the D:N ratio, the respiratory quotient, the blood sugar, and tissue glycogen—which have dominated all studies of the metabolism of sugar, and the reactions of these to the administration of insulin in both the diabetic and the normal animal form the data from which the argument is to proceed. So, by way of chapters dealing with experimental hyperglycaemia and hypoglycaemia we are led to a discussion of the mechanism of the action of insulin. This discussion could hardly be satisfying for the author was in a sorry position. It was written when experimental research was at an impasse. It is a story of promises unfulfilled, clues abandoned, illusions destroyed. In our haste we had said that the discovery of insulin provided a key to the main problems of carbohydrate metabolism, that a few conventional experiments with this new agent would carry us far along the road. A riot of experiment engulfed us, unsettled our criticism, damped our easy optimism, and left the subject almost worse confounded than before. What happens to the sugar which disappears from the blood of the normal animal under the influence of insulin? It is not converted into glycogen, it is only in small part oxidized. It is lost. Find it, and the great secret of carbohydrate metabolism will be revealed. Such is the impression that is left by much of the work upon the action of insulin, and, as Professor Macleod's patient review clearly reveals, the search for the hidden sugar led us into many vain imaginings. And now it would seem that where the great mystery was sought there is no mystery. Dr. H. H. Dale and Dr. C. H. Best are persuaded from work recently carried out by them that the lost sugar is, in fact, converted into glycogen in the normal animal as well as in the diabetic. It is a misfortune that the author's difficult task of summary could not have been lightened by the knowledge of this simplification, but it is of the nature of monographs that they should deal with a live subject, and they must, therefore, be always one stride behind the vanguard of knowledge. Professor Macleod has given us a patient, laborious, critical record of recent work in this great problem in metabolism. The book is a comprehensive chronicle rather than an inspired message—but this is no problem to be pursued amongst the clouds.

The second book<sup>2</sup> to which reference has been made is by Dr. A. CHOAY. In it interest is centred on the hormone itself rather than on insulin as a lever in the machinery of metabolism. We are taken much farther back in the history of physiology—back to Claude Bernard and von Mering. The growth of the faith in a pancreatic hormone is traced in detail up to the discovery of insulin. In still greater detail are considered the chemical and physical properties of insulin and the methods for its preparation, its pharmacology, physiology and therapeutics, and the interesting interrelations of the pancreas and other organs of internal secretion. A very satisfactory feature of the work is an elaborate bibliography, which must approach a complete list of all papers of real interest to the subject. Fifteen hundred original papers are included. The price fixed by the publishers, should it withstand the further vagaries of the exchanges, is modest enough to enhance the attractiveness of this book as a standard work of reference.

Both Professor Macleod and Dr. Choay have achieved a considerable measure of success in turning the great library of pancreatic studies to their special purposes, and the choice of the reader may well rest upon his own particular interests. In these days the writing of a careful monograph in a wide field is a task which brings little satis-

<sup>2</sup> *Carbohydrate Metabolism and Insulin*. By John James Richard Macleod, F.R.S., M.B., LL.D., Aberd., D.Sc. (Hon.) Toronto. *Monographs on Physiology*. London and New York: Longmans, Green and Co. 1926. (Med. 8vo, pp. xii + 357; 33 figures. 18s. net.)  
<sup>3</sup> *La Sécrétion interne du Pancréas et l'Insuline*. Par André Choay. Paris: Masson et Cie. 1926. (Roy. 8vo, pp. xx + 570; 7 figures. 8s. 4d.)

faction of any sort to the author. It is therefore fitting that the spirit of those who discipline their pens to the labour should not pass without acknowledgement.

### THE PITUITARY.

*The Comparative Anatomy, Histology, and Development of the Pituitary Body*,\* by G. R. DE BEER, is the sixth of a series of monographs at present being issued under the editorship of F. A. E. Crew and D. Ward Cutler. The series is designed with a very definite aim. The increasing specialization in biological inquiry has made it impossible for any one author to deal adequately with current advances in knowledge. It has indeed become a matter of considerable difficulty for a research student to gain a correct idea of the present state of knowledge of a subject in which he himself is interested. To meet this situation the textbook is being supplemented by the monograph. De Beer has fully grasped the intention of the editors and has produced a book which will save an infinity of trouble to the student who is embarking on a research into the functions of the pituitary body. It is true that such research lies in the domain of physiology, but it is none the less true that in the planning out of experiments on a complex organ such as the pituitary gland, a good knowledge is required of the various forms exhibited by the gland in different animals, so that the most suitable for experimentation may be selected. Moreover, it is necessary to know the component parts of the gland, with a view to defining their respective functions; and also to know what parts are homologous in the series of animal forms, in order that the results of experimentation may be comparable. The important respects of value in differences, though it may fall short in defining the precise nature of the functions. On all these matters de Beer has furnished a clear and well illustrated account, and in such detail as to render superfluous much reference to original articles. A complete bibliography up to date is, however, appended, as a supplement to the exhaustive bibliography to be found in Stendell's work on the hypophysis.

The book is the product of an original research involving the examination of a large number of pituitary glands, and in order that the work should be true to nature the author has used no material that had not been properly fixed within half an hour of the death of the animals, and for this reason human material has not been employed. After a preliminary chapter dealing with the technique of staining sections, the author discusses, separately, the macroscopic anatomy, the histology, and the development of the gland in the several orders of animals—in mammals, birds, reptiles, amphibia, the bony fishes, selachians and cyclostomes. An interesting chapter is devoted to the evolution of the gland. Thus, in its most primitive form the hypophysis occurs as a depression in the ectoderm in front of the mouth, into which one of the head cavities acquires an opening (amphioxus); later it is displaced into the buccal cavity, its epithelium becomes ciliated, and its function apparently is to create a current of water. In its further evolution the depression sinks beneath the surface and communicates with the exterior by means of a duct, thus taking the form of a secreting gland. The final step is the complete separation of the hypophysis from the surface and its connexion with the infundibulum, the organ thus acquiring the endocrine mode of secretion. A short chapter containing comparative observations, together with some practical advice as to the most suitable forms for experimentation, concludes a very interesting and useful volume.

### THE CEREBRUM AND CEREBELLUM.

*The Nouveau Traité de Médecine*† is an ambitious work, projected to appear in no fewer than twenty-two volumes, of which several have already been reviewed in these columns. The present volume, No. 19 in the series, is devoted to

the diseases of the cerebrum and cerebellum. To this subject more than a thousand pages is given, and this extensive text is richly illustrated by numerous figures and plates, some in colour. The reader is therefore provided with a veritable mine of information, and this at a very reasonable cost. In a work of this magnitude it is inevitable that some inequality of treatment of the various subjects should occur, but this fault is here at least at a minimum, and an adequate presentation of the subjects is guaranteed by the names of the numerous distinguished authors who contribute to its pages.

If any particular sections can be chosen as being of special value, those dealing with the diseases of the cerebellum, from the pen of M. Andre Thomas, and the account of the cerebral tumours, by MM. Roussy and Cornil, deserve mention. There are few modern accounts of the subject which can rival M. Thomas's extensive account of the physiology and diseases of the cerebellum. The chapter on the tumours of the cerebrum is also particularly rich in valuable pathological matter.

The articles on cerebral syphilis and general paralysis of the insane can both be warmly commended; the pathological and clinical descriptions are alike excellent, while the account of the microscopic anatomy of general paralysis is enriched by many illustrations, including some beautiful coloured plates. A useful chapter, and one on a subject which is seldom adequately treated in the ordinary textbook, is that on the senile brain by M. A. Comte. Dr. Levy-Valensi's account of the infantile encephalopathies is unusually full and good, and here again the value of the text is much enhanced by very graphic figures. The last chapter, on the various forms of labyrinthine disturbance, is a brief but highly useful summary of a subject which often receives scant attention in textbooks.

There can be no question as to the value of this book, both to the neurologist and to the general physician. Its only fault is its weight, which is so great as to preclude it being read in any comfort except at a table or a reading desk.

### MATERNITY AND INFANCY.

In the course of the book *Maternity and Infancy*,\* written with the direct simplicity which characterizes the work of Dame MARY SCHARLIEB, it is stated that it is intended "chiefly for the instruction and comfort of expectant mothers." This is too modest a claim. Rather it might well be placed in the hands of medical students when they are about to begin a course of practical obstetrics, and to nurses also who are preparing for the C.M.B. To both it will be of great interest and value, but it is just a question whether an expectant mother, however well informed, would be "comforted" by a discussion of the treatment of the possible complications of pregnancy. The author deals fully with these matters, describing in detail the medical treatment, and not hesitating to mention divergent views of obstetricians.

Before practical experience has been obtained in midwifery, the student frequently finds certain gaps in the usual textbooks. It is just these gaps which are here skillfully bridged, and a continuous story thus presented, and a lucid and connected account of ante-natal, natal, and post-natal conditions afforded.

With her long and varied experience Dr. Scharlieb brings to bear upon the whole subject of pregnancy a breadth of vision and a ripe wisdom which appear between the lines of this book. All through it wholesome advice for expectant mothers is given. Controversial points are touched upon with restraint, and dogmatic assertions are not made, though they might well become the writer. Modern ideas are incorporated with the sound teaching that has stood the test of time. In these days, when a certain amount of medical knowledge is found in every household, Dame Mary Scharlieb sounds a timely note of warning against the interference of well intentioned relatives.

The book is dedicated to the First Obstetric Unit in London at the London (Royal Free Hospital) School of Medicine for Women, and to its director, Professor Louise McHroy. It deserves to be widely read.

## NOTES ON BOOKS.

PROFESSOR MATTHEWS is to be congratulated that within ten years a fourth edition<sup>7</sup> of his *Physiological Chemistry* should be called for. The material which has been added since the third edition deals with the discoveries of Sir James Irvine and his pupils in regard to sugars, the clotting of the blood, the chemistry of the skin and eye, insulin, and the chemical aspect of the defences of the organism against disease. When the historical order of development of a subject is dealt with it is clearly stated. The chapter on the carbohydrates may be taken as an example: it is made interesting by its account of the work of Berthelot, Priestly, and Baly on photosynthesis and photocatalysis. Professor Matthews himself is an authority on the oxidation of sugars. Again, in the chapter on animal heat, the story of the work of Lavoisier is retold with freshness, and Lavoisier's conclusions are given in his own words from the original papers. No fewer than 275 pages are given up to "Practical work and methods"; and here the watchword is "thorough." When colloids were under discussion we should have expected some allusion to the use of the clay filter. There is no index of authors' names, which, when supplied, is always convenient; but at the end of each chapter there is a full bibliography.

The *Textbook of Physiology*,<sup>8</sup> by Dr. ZOETHOUT, is a more or less judicious compilation, and has very few references to original papers. Such references as are given are almost exclusively to American authors. It would seem that those readers more particularly addressed are students of dentistry, pharmacy, and those at "normal schools." It is difficult to understand the principle on which the various sections or chapters are arranged; why, for instance, the ferments should be treated as early as in Chapter II, before any chemistry has been studied. In this chapter the word "dead" is used as equivalent to "non-living," but dead can properly be applied only to that which has lived. The classification of the properties and characteristics of living matter does not seem to be based on any ascertainable principle. The first property to be mentioned should have been affectability, called in this book irritability; but "contractility" is given the first place; and the reader is left to think that it is as universal as irritability, which it is not. Excretion, respiration, digestion, and even absorption are all set down in the same list with the far more comprehensive term "metabolism." The allusion to "inertia" (p. 21) is misleading, for from it we are left in doubt whether the author is referring to inertia of masses in the ordinary Newtonian sense or to "physiological" or "functional inertia" and "functional momentum" in the sense in which Fraser Harris, J. Arthur Thomson, and Noël Paton have used it. Where the author is practical he is much better; the treatment of respiration, "taking cold," and baths is timely and sensible. Some of the diagrams are excellent; some sketchy, or stiff and formal.

The third volume<sup>9</sup> of the series of ophthalmological monographs, by Professor TERRIEN of Paris, deals with the lens. It is clearly written and freely illustrated, as were the two previous numbers of the series. Anatomical and physiological considerations occupy rather more than half the volume, the remaining portion being devoted to difficulties of accommodation and the occurrence and treatment of opacities and injuries. Like its predecessors the book is authoritative, and is not spoilt by an excess of detailed descriptions.

To the prospective settler and even to the tourist the Union Castle Steamship Company's *South and East African Year Book and Guide*<sup>10</sup> offers a mass of useful information in an admirably concise form. The handbook includes, besides an atlas of 64 pages and a general gazetteer, summaries of the immigration and land laws, and reviews of the present position of industry and agriculture, detailed descriptions of the towns and country, and the routes by which the various districts of the territories covered may be reached, and discussions of the cost of living. Very full accounts of climate are given, with special reference to suitability for invalids, and a section headed "Sport and Research" deals with the distribution of game and fish and the local and general facilities for sport. There is an adequate index.

<sup>7</sup> *Physiological Chemistry*. By Albert P. Matthews, Ph.D. Fourth edition. London: Baillière, Tindall and Cox, 1925. (Roy. 8vo, pp. xviii + 1233; 109 figures. 30s. net.)

<sup>8</sup> *A Textbook of Physiology*. By William D. Zoethout, Ph.D. Second edition. London: Henry Kimpton, 1926. (Med. 8vo, pp. 616; 186 figures. 18s. net.)

<sup>9</sup> *Sémiologie Oculaire: Le Cristallin*. Par Félix Terrien. Paris: Masson et Cie, 1926. (Roy. 8vo, pp. 240; 158 figures. 6s.)

<sup>10</sup> *The South and East African Year Book and Guide for 1926*. Edited for the Union Castle Mail Steamship Company by A. Samler Brown, F.R.M.S., and G. Gordon Brown, F.R.G.S. London: Sampson Low, Marston and Co., Ltd. (5s. 6d. post free.)

The *Transactions of the American Climatological and Clinical Association*<sup>11</sup> for the year 1925 include numerous articles dealing with diseases of the respiratory and circulatory organs and with climatology and hydrology. Dr. V. Y. Bowditch contributes some interesting reminiscences of his student life in Europe in 1879 to 1881, when he visited Vienna, Leipzig, Strasbourg, Paris, and London.

## PREPARATIONS AND APPLIANCES.

*Portable Apparatus for Administering Carbon Dioxide.*

DR. H. WHITRIDGE DAVIES (Department of Therapeutics, University of Edinburgh) has designed a portable apparatus for administering carbon dioxide mixed with air in conditions with respiratory failure, such as shock, anaesthesia, alcoholic and narcotic poisoning, carbon monoxide poisoning, drowning, and some of the accidents in obstetric work. The advantages of carbon dioxide inhalation are that it acts promptly, its maximum effect being obtained in ten seconds, that its action lasts as long as the inhalation continues, and that the increased pulmonary ventilation is obtained without any great increase in metabolism. Dr. Whitridge Davies had the assistance of Professor Briggs of the department of mining in the University of Edinburgh, and of Messrs. Sparklets, Ltd., in designing his apparatus. A sparklet 6½ inches long and 3/4 inch in diameter contains 25 grams of liquid carbon dioxide and will provide twelve litres of gas, so that if the maximum flow allowed be two litres a minute, the sparklet will last at least six minutes. The sparklet is inserted in a holder on to which a cap with a piercing pin, a rubber collar, a needle valve, and a lateral exit pipe is screwed. As the cap is screwed up the piercing pin perforates the sparklet, and the rubber collar prevents the escape of gas; the needle valve is then unscrewed to the required amount, and the gas escapes through the exit pipe underneath a Schimmelbusch mask, or straight into the patient's mouth, or through a glass funnel attached to a tube, or through a catheter passed into the naso-pharynx. With a little experience the needle valve will supply a gentle, steady, easily regulated stream of gas, and a refill can be easily inserted.

*A Transparent Eye-shade.*

MR. E. N. HUGHES, assistant surgeon to St. Paul's Eye Hospital, Liverpool, has designed an eye-shade of celluloid, for use whenever a shade is required which will not exclude light. It is of special value when the only seeing eye needs shading, the other eye being blind. In such a case, after removal of foreign bodies, or after minor operations with cocaine, the sound eye can be protected by the transparent shade and the patient can find his way home. The shade will be useful also, it is considered, when the eye needs protection, and yet the eyelids should be kept open, as in conjunctival conditions and after lid and squint operations. A series of holes along the upper margin prevents moisture from the inner surface of the shade; the shade can be washed with ordinary soap and water, and can be obtained from Messrs. Boots, Liverpool.

## ROYAL MEDICAL BENEVOLENT FUND.

At a recent meeting the Committee considered forty cases and voted £507 to thirty-four applicants. The following are notes on some of the cases relieved.

Widow, aged 70, of M.R.C.S.Eng. who died in 1896. She has worked hard for the last thirty years, and has kept and educated her three children, who are now able to maintain themselves but no more. She has been removed to a nursing home. Her income is £38 per annum, and the Fund was asked to help with the nursing home fees, which amount to 2 guineas a week. Voted £6 in three monthly instalments of £2 each.

L.R.C.P. and S., aged 69, who practised in Scotland, but is now suffering from the effects of cerebral haemorrhage. His friends asked for assistance to meet expenses; another charity is also being approached. Voted £40 in twelve monthly instalments.

Widow, aged 65, of M.D.Glas. who died in 1903. Of two daughters, one, aged 24, is at home, and has £30 per annum; the younger, aged 22, is now self-supporting. Since 1917 the applicant and her daughters have been fortunate in having a cottage at a nominal rent of £5 per annum, but they now have to vacate it. Voted £10.

Widow, aged 49, of M.B.Edin. who died in March. She has two sons, one, aged 20, who earns £120 per annum; the younger, aged 16, is at present living with friends, but may, it is hoped, be sent to Australia. The applicant hopes to get a post and become self-supporting. Voted £12 in three monthly instalments of £4 each.

M.D. 1880, aged 72, who practised in London, but has had to give up practising on account of failure of sight. His four children help, but the brunt of the household expenses fall on the daughter, leaving insufficient for her own personal needs. Voted £40 in four quarterly instalments of £10 each.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, K.B.E., at 11, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58, Great Marlborough Street, W.1.

## MEDICAL PROGRESS IN MALAYA.

## KING EDWARD VII COLLEGE OF MEDICINE AT SINGAPORE.

The opening in February of the new King Edward VII College of Medicine at Singapore was briefly described in our issue of April 3rd (p. 623). Additional information has now reached us, together with photographs of the college and the new general hospital, some of which are here reproduced. The frontage of the college measures 120 feet, and its main feature is a lofty façade of fluted Doric pillars, 50 feet high. The façade is flanked by wings set back slightly and adorned by sculptural panels representing the teaching and practice of medicine. Over the central doorway there is a striking mass of relief sculpture, and the names of various sciences appear over the subsidiary entrances along the front. The building is constructed of ferro-concrete, and cost about £58,000. The main hall seats 500 persons, and, in addition to four laboratories, there are lecture and research rooms, good library accommodation, reading rooms, and a museum. An electro-cardiograph has been installed at a cost of £400, and a special effort has been made to bring the equipment in other ways up to the most modern requirements. The building used previously as the college has now been converted into an anatomy school.

There are usually about 100 to 150 students at the college; some are maintained by the Government, some pay fees, and the remainder are in receipt of scholarships and exhibitions. The number of applicants for admission as students is now so large that selection has become necessary, candidates being chosen mainly on the results of the Senior Cambridge examination. At one time many students came from India, and a few from the Dutch Indies, but the Dutch Medical Service has established a well equipped medical school at Weltevreden, and preference is now given at Singapore to candidates from Malaya, for whom two commodious hostels have been erected. A dental school is now being opened for the first time, with a course lasting four years.

Medical education in Singapore may be traced back to 1892, when a course was started for assistant surgeons, but was abandoned owing to the small number who attended. In 1905 a group of enlightened Chinese presented a petition to the Governor, asking for the establishment of a medical school, and proved their sincerity by raising a sum of over £9,000. By the conversion of existing buildings and the construction of a lecture room and chemical laboratory, the Government inaugurated a medical school, which was opened by Sir John Anderson in 1905, and five years later the first group of students received their diplomas. The institution was known until comparatively recently as the King Edward VII Medical School, but has now adopted the title "College of Medicine." In 1913 a professorship was founded by the King Edward VII Memorial Fund, and in 1925 the International Health Board of the Rockefeller Foundation endowed two professorships on condition that the Government provided a third chair; the chairs are in biology,

biochemistry, and bacteriology. The present considerable cost of upkeep is borne jointly by the Government of the Straits Settlements and the Federated Malay States.

## NEW HOSPITAL, SINGAPORE.

As shown in the general view, the college is situated close to the extensive general hospital, which was formally opened by Sir Laurence Guillemard, Governor of the Straits Settlements, on March 29th. The site on which

the hospital is built included originally a conical hill and a deep ravine, so that the building of a hospital in one block would have been impossible. The hill has been levelled and the ravine filled, remaining inequalities of level being skilfully used in constructing the new buildings. The hospital consists of three main blocks of wards, hostels for nurses and students, residential quarters for dressers, a pathological

laboratory, an out-patients' block, a maternity hospital, and other buildings. The pavilion type has been adopted throughout, a long central corridor dividing the wards on each side, which thus obtain abundant light and air. Blocks for the first and third class wards have five pavilions of two stories each, the central corridors being 500 feet long, and the pavilions 280 feet from wing to wing. It is hoped that the scheme will be completed next year, when accommodation will be available for 800 patients. The total cost of the building will be about £525,000.

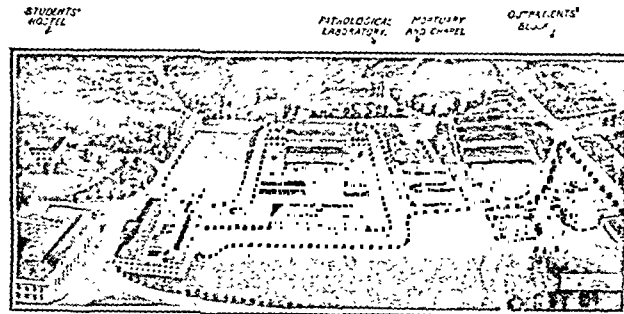

The wards, operating theatres, and x-ray rooms were planned in consultation with the medical officers, who considered carefully all the various details, so that the maximum efficiency might be obtained. The main block of first-class wards provides 256 beds. It has a small corridor ending in a spacious waiting room for the nose, throat, and ear department; in this corridor are entrances to the theatres for clean and septic cases respectively. Each theatre is fitted with a special installation for the provision of illumination similar to that of daylight. Terrazzo floors and sani-onyx and tiled walls facilitate cleansing. Throughout the building

all internal angles are covered, and the doors and fittings are so designed as to avoid there being any projecting mouldings. Sterilizing and disinfecting chambers open off the main corridors of this block, and near them are well equipped kitchens, for Europeans, Chinese, and Mohammedans. As will be seen from the illustration, the wards are high and well lit: adequate artificial ventilation is available, and their floors are covered with rubber sheeting, which renders them noiseless and easily cleansed. Two of the four pavilion wards contain forty-eight beds, one fifty-six, and another seventy-two; there are thirty-two beds in a special ward devoted to the treatment of tuberculosis: the total number of first class beds is 256.

A special ward is provided for seamen. The admission block of this building comprises three floors, and in addi-

King Edward VII College of Medicine.

General View of New Hospital.

tion to the administration offices, observation and detention wards are provided. All the wards have verandahs which serve as day-rooms for the convalescent patients; beds can also be moved out on to these verandahs, so that the full benefit of light and air.

The block of third-class wards similarly includes five pavilions connected with each other by corridors, staircases, and lifts. The floors of the wards are in smooth cement, and all the sanitary blocks are cut off from the main buildings by ventilation lobbies. There are seventy-two beds in the reception ward and one of the ordinary wards; the three other wards each contain ninety-six beds. Two second and third class blocks for female patients have each accommodation for seventy-two. The admission block in this building has two floors, and includes subadministrative offices, a dispensary, and observation, detention, and reception wards. There is also a minor operating theatre block, with a theatre on each floor. Provision is made in an isolation block for chronic and observation cases. Separate kitchens for Mohammedans, Sikhs, and Bengalis are provided in the third-class block.

A simple style of architecture was adopted throughout so that all the buildings might be constructed as economically as possible. The new hospital has been designed in accordance with the most modern principles, applied with special consideration for the requirements of tropical conditions. The buildings were erected independently, eleven contractors being employed: each building was equipped and occupied as soon as it was ready. Adequate hospital accommodation is thus now provided for a growing city of over 400,000 inhabitants, for whom previously only 250 beds were available. The building was begun in 1920.

First-class Wards and Administration Block.

Interior of Ward for Seamen

#### OPENING OF THE HOSPITAL BY THE GOVERNOR.

Speaking at the opening ceremony on March 29th, Dr. A. L. Hoops, the principal civil medical officer, referred to

the active support for many years given by the Governor, Sir Laurence Guillemard, to the improvement of public health in Malaya, the reorganization of the medical departments after their depletion during the war, and his encouragement of the provision of the most modern methods for the prevention and treatment of disease. He reviewed the progress made, and mentioned particularly the

establishment of a school for sanitary inspectors, the highly successful antimalarial and hookworm campaigns, the extension of stationary and travelling dispensaries in many districts, the erection of hospitals and leper asylums in Penang, Malacca, and elsewhere, and the provision of quarantine stations, convalescent homes, and maternity hospitals. The Governor, replying, emphasized the high importance in administering a tropical colony of attention to the public health. For this it was necessary to provide such material agencies as institutions for medical treatment, with fully trained and skilful medical and nursing staffs, but it was also vital that those concerned in this work should be inspired with, and be able to communicate to their patients, that faith which was the central principle of the Aesculapian cult from which the art of healing had sprung. Galen's message, "He cures most successfully in whom the people have the greatest confidence," would be fully accepted and its implications recognized in practice by each member of the staff of the new hospital.

#### SOCIETY FOR THE PREVENTION OF VENEREAL DISEASE.

The seventh annual general meeting of the Society for the Prevention of Venereal Disease was held at 143, Harley Street, on July 28th, Dr. J. H. SEQUEIRA, the chairman of the Executive Committee, being in the chair.

The following resolution was proposed by the CHAIRMAN, seconded by Mrs. LATTER, chairman of the Women's Committee, and carried unanimously:

That this annual general meeting of the Society for the Prevention of Venereal Disease respectfully urges the Government to grant facilities to the Venereal Disease Act, 1917, Amendment Bill, in view of the support that it has received from the British Social Hygiene Council and the Society for the Prevention of Venereal Disease and the medical members of the House of Commons.

The CHAIRMAN suggested that the first sentence of the memorandum of Sir George Newman, Chief Medical Officer of the Ministry of Health, entitled *An Outline of the Practice of Preventive Medicine*, should be adopted as the motto of the society, the sentence running: "The first duty of medicine is not to cure disease but to prevent it." The report of the late Sir William Leishman on the health of the army was quoted, and the remarkable fall in the incidence of venereal

disease during the last four years was brought to the attention of the meeting, which, the report stated, was attributable to the advance made in the prevention, diagnosis, and treatment of these diseases, and to the vigorous antiveneral disease propaganda.

Mr. H. WANSEY BAYLY, the honorary secretary, gave an account of the society's work during the past year, and said that "not only in this country, but throughout the civilized world, there were indications that there had developed an appreciation of the danger of neglect of the venereal menace and a recognition that education in immediate self-disinfection was one of the important means of meeting this drain on the health, industry, and purse of nations and individuals."

Mr. BASIL PETO, M.P., was elected president of the society, and stated that the House of Commons was beginning to realize the importance of the society's work, and that all the medical members of Parliament with one exception, and many lay members of all political parties, had promised their support to a bill to amend the Venereal Disease Act, 1917, so as to permit the sale by chemists of approved disinfectants, accompanied by approved printed instructions, as recommended in the report of Lord Trevellyn's Committee of Inquiry.

Mr. HARRY MACHIN, the honorary treasurer, emphasized the necessity of obtaining financial support from the public in view of the fact that the society received no Government grant and was entirely dependent upon the subscriptions and donations of those members of the public who realized the national importance of its work.

# British Medical Journal.

SATURDAY, AUGUST 7TH, 1926.

## SCIENCE AND THE STATE.

IN his gracious message to the British Association for the Advancement of Science, which the Prince of Wales as President read at the opening meeting at Oxford on Wednesday evening, King George aptly recalled the only other occasion upon which a member of the Royal Family had occupied the chair. It was at Aberdeen in 1859, as the Prince reminded his hearers, that his distinguished great-grandfather, Prince Albert, held that position and delivered a thoughtful and far-seeing address in which he pleaded the "sacred cause" of science. Although by that time science had attained a more assured position than it held at the Oxford Meeting of the Association in 1832, when a well known hymnologist included Michael Faraday and David Brewster in what he called "a hodge-podge of philosophers" unworthy of honorary degrees, the next meeting at Oxford (in 1860) showed how badly the clerical opponents of Darwin had read the signs of the times, and Wilberforce's ill-judged and ill-informed attack recoiled upon himself. Well might Huxley say "The Lord hath delivered him into my hand!"

The Prince Consort in 1859 was able to show that the Association had accomplished much, and he claimed that philosophers were "not vain theorists, but essentially men of practice—not conceited pedants, wrapped up in their own mysterious importance, but humble inquirers after truth—God's truth—God's laws as manifested in His works, in His Creation." Even now the Prince of Wales found it necessary to rebuke those who still hold "an attitude towards science which personifies it as the ancients personified the powers of darkness." The attitude of the metaphysical philosopher has changed, and instead of denouncing the natural philosopher as impious, he is inclined to twit him with failure, in an attempt he has not made, to explain this sorry scheme of things. We are too often told by superior persons that Huxley, Darwin, and Tyndall set out to explain everything and that they and their followers have signally failed. But these great men explicitly disowned any such intention or attempt.

It is interesting to note that in the Prince Consort's address in 1859 there was no direct reference to medicine or its allied sciences, save for a passing mention of chemistry, and only a few medical contributions are to be found in the report of the work in the Section of Physiology, but among those who submitted papers were such well known men as G. H. Lewes, Michael Foster, and A. B. Garrod. In the address of the Prince of Wales, on the other hand, medicine occupies an important place, and especially State medicine and hygiene in their widest sense. Nothing more clearly marks the difference between 1859 and 1926 than the attitude of science and the State to one another. As the Prince says: "There was an element of mutual distrust between Science and the State. A strong body of scientific opinion was avowedly afraid (as Sir George Airy phrased it) of organizations of any kind dependent on the State." There may be objections to the

methods of the State, but nowadays men of science, probably the great majority of them, realize that it is better that the State—or the community, as the Prince put it—should interfere and take action rather than that beneficial action should not be taken at all. So far the forebodings expressed by Sir George Airy and others have not been justified.

The appointment of the Medical Research Committee under the Insurance Act and its development into the Medical Research Council directly responsible to the Privy Council has, thanks to judicious direction, led to great gains in knowledge and is leading to advances in treatment. Now that the instruments and methods of research are so complicated and often laborious, it is no longer a question of a microscope, a few test-tubes, and the spare moments of a busy practitioner. Regret it though we may, we have to admit that great advances are only likely to be made by team work in well equipped laboratories and by men who are able to devote most, if not all, of their time to the work. Collective investigation, which was long ago fostered by the British Medical Association, plays a large part in public health studies, and its possibilities have by no means been exhausted; but to be successful it requires the attainment of a certain minimum degree of skill in the investigators. We remember to have seen an estimate of the profit and loss account, if we may so style it, between the French State and the endowment of research, in which it was demonstrated that if only Pasteur's researches had resulted from these endowments the profit from the economic application of his scientific work would be enormous. The Prince told his hearers of more than one piece of research work which missed its original aim yet resulted in valuable results achieved by progress in a direction not anticipated. For instance, the Government's fuel research station has not yet proved the hoped-for commercial possibility of the low temperature treatment of coal which would result in the production of the more economical smokeless fuels, oils and gas, but it has shown the possibilities of unexpected economies which are well in excess of the cost of the research.

Few people, perhaps, fully realize the magnitude of the work undertaken by the Committee of the Privy Council for Scientific and Industrial Research, and the President of the British Association has rendered a public service in drawing attention to it. There are eleven research boards under this department, some of which direct the work of committees to the number of thirty-six in all, as well as the Geological Survey and the National Physical Laboratory. The Building Research Board has made most extensive and valuable investigations into every circumstance affecting house building, and aims at creating a real science of building. The work of the Food Investigation Board is obviously of the very greatest importance. On its researches depend questions and decisions fraught with the very greatest effects on the health and the future physique of the nation. Not only does it deal with the actual composition of food, its adulteration, and the effect of preservatives of various kinds, but also with the great and increasingly important question of cold storage and its drawbacks and advantages. Notwithstanding all these and other Government activities there still remains, as the Prince was careful to tell his hearers, a vast field for the enterprise and industry of societies and individuals who are interested in various branches of science. The Indian Government has always favoured scientific methods, and its

investigations have long been famous. The Dominions are now, like the Mother Country, endowing and carrying out researches into the manifold problems raised by the development of new countries, and the introduction, not always fortunate, of organisms from their old habitats into new environments.

The address of the Prince of Wales ends on a note of cheerfulness and hope and belief in the future benefits to be derived from science. Whether the coming years are to be bright or gloomy, this much is certain—that only by employing scientific methods to the fullest possible extent can this nation hope to maintain its standards of life and comfort.

### THE WRITING OF MEDICAL PAPERS.

A STERN critic has said that the most serious vices of modern English prose are indifference to the origin and proper meaning of words; neglect of order and rhythm; a tendency to prefer the abstract to the concrete; the use of nouns instead of verbs; and an indolent acquiescence in worn-out phrases. But these abuses of language, he added kindly, are less harmful than the general paralysis of structure which deforms almost all modern writing. Criticism of this sort, though it may be salutary, is negative, to say the least. Those who like positive advice will prefer the opening sentence of *The King's English*: "Any one who wishes to become a good writer should endeavour, before he allows himself to be tempted by the more showy qualities, to be direct, simple, brief, vigorous, and lucid."

It would be strange if medical authors—whose main business is not letters but science and sick people—were free from the errors of current prose. For their guidance there are, however, several finger-posts. Sir Clifford Allbutt's admirable book on the composition of scientific papers<sup>1</sup> has helped countless writers of graduation theses to put their material together in clear and logical order, and to express themselves in decent English. Many besides Cambridge men are grateful to that little green volume for its hints on literary craftsmanship, and its warnings against such common blemishes as wordiness, slovenly arrangement, and the abuse of technical jargon. Further practical aid has been given by Sir Humphry Rolleston in his pamphlet on the writing of theses for medical degrees,<sup>2</sup> and by Mrs. M. H. Mellish, editor of the Mayo Clinic publications, in her small manual on the preparation of medical papers.<sup>3</sup> Another pamphlet of suggestions to medical authors, popularly known as the "A.M.A. Style Book,"<sup>4</sup> has been issued for many years past by the American Medical Association, to help would-be contributors in arranging manuscript, and to show the typographical practice laid down for the *Journal of the American Medical Association* and its associated publications. The veteran editor of that journal, Dr. George H. Simmons, some time before he relinquished its active conduct, gave an address on medical periodical literature, and this review of an experience of thirty years of medical journalism was discussed in our issue of April 29th, 1922. Having noted the faults that disfigured so many of the manuscripts sent to him, Dr. Simmons proposed one remedy for them all: that the art of writing should be more carefully

studied and all writings submitted to thorough revision. Medical authors, in short, must learn to write better and take more trouble.

For the benefit of those seeking to follow his good counsel Dr. Simmons and his successor, Dr. Morris Fishbein, collaborated early last year in a series of articles which appeared at weekly intervals in their columns. These were in large part an outgrowth of the "style book" already mentioned, and, with some added matter, they are now republished in book form under the title *The Art and Practice of Medical Writing*.<sup>5</sup> Our colleagues begin by giving their readers an idea of what a paper ought to be, and why three-fourths of the manuscripts voluntarily offered to the *Journal of the American Medical Association* are rejected. Here we are glad to see the point made firmly and plainly that, while an author's rights must be respected, the medical editor's first duty is to his readers, whose rights are paramount. The second chapter indicates some common vices of style, with "specimens from real life"; the third discusses choice of subject and material, with hints on the writing up of a case report for publication; the fourth is mainly about the importance of title and sub-headings in the framework of a well built paper; and the fifth is in effect a protest against the misuse of certain words and phrases (like "to operate the patient") by medical authors on the other side of the Atlantic, and the overdoing of our old friend "marked" as the maid-of-all-work medical adjective. The next five chapters, on such things as spelling, abbreviations, and the use of capital letters, follow American usage, which differs a good deal from that followed by English printers; in this country Horace Hart's rules for compositors and proof readers at the Oxford University Press form a convenient guide. Chapter eleven tells the beginner how to hunt up references and what to avoid in compiling a bibliography. This is followed by three chapters on the technical side of preparing manuscript, pictures, charts, and tables for the press. Would that we could persuade all our own contributors to take it from Dr. Simmons that there really are "practical reasons why editors prefer good, clean copy."

The concluding chapters give sound advice on revising the text of an article and the correction of proofs. The former is especially valuable for its insistence on the pruning knife as the writer's best friend. Here will be found the sad but most instructive tale of an essay printed in a medical journal (American but unnamed) which "presented most of the faults mentioned in this book, as well as many of those referred to in elementary books on grammar and rhetoric." This paper, 2,800 words in length, had evidently been flung to the printer without revision of any kind. The average number of words to a sentence was 84. By way of object lesson one paragraph, consisting of a single inchoate sentence of 208 words, is quoted. The reader then sees, on the opposite page, how a subeditor who knows his business could have cut this down and broken it up, greatly to its advantage, into seven sentences containing 123 words in all. With further pruning, also shown in graphic form, the paragraph is brought down to five sentences and 98 words.

What, then, is the conclusion of the whole matter? It will be found in a sentence of Clifford Allbutt's: "Take pains, therefore, with yourself first, then with your reader." As we have shown, ample help is now

at hand, in guide-books and pamphlets, for those who aspire to the writing of medical papers. The rest is a matter of taking pains. "Write and re-write," says Dr. Simmons, "re-write again, and then revise!" For, contrary to the view of Dogberry (and of some others, even in our profession), writing does not come by nature.

#### ALCOHOLISM IN FRANCE.

SOME months ago we noted the appointment by the Académie de Médecine in Paris of a committee to investigate the increase of alcoholism in France. At that time the sale of absinthe had been forbidden, but some alarm had been caused by the increased consumption of what were known as absinthe substitutes. The report of the committee, presented to the Académie by Dr. Marcel Labbé, is an interesting document of some length written with a fair measure of restraint. It appears that before the war many were becoming concerned at the increase in alcoholism in France. During the war restrictions were imposed on the manufacture and sale of strong alcoholic beverages, with the result that their consumption was considerably reduced. The reduction of alcoholism which followed has not been maintained, and statistics show that the admissions to asylums for lunacy due to alcohol, which during the war had decreased enormously, have since 1919 increased until they now exceed the figures of 1914. The committee attributes this increase in alcoholism very largely to the home manufacture of brandy. The privileges of the *bouilleurs de cru* were greatly restricted in 1916; they were restored in 1923, with the result that in some villages, as one speaker put it, every school child carries in his basket food that has been flavoured with brandy; meanwhile the villagers declare that their spirits must be harmless, since they are a "natural product," made at home. The committee finds that the prohibition of absinthe has been most successful, and that there is no sign of an alcoholism from the popular anise essence by which it has been replaced comparable to that which was formerly caused by absinthe itself. At the same time Dr. Cazenave's demand for more vigorous control of absinthe substitutes is approved. It appears that the consumption of spirits, liqueurs, strong wines, and appetizers, although increasing, has not yet reached the pre-war level. The consumption of wine is also a little less than in 1913. Beer-drinking is very much less, possibly owing to the destruction by the Germans of many large breweries in Northern France. The consumption of cider varies with the productiveness of the apple trees. Speaking generally, the consumption of strong distilled liquors is tending to be replaced by fermented liquor. The committee finds, however, that there has been considerable change in the classes of people who now drink to excess. There are fewer really heavy drinkers than formerly; there are more people, and of a different class, who take too much, and the report deplores the extension of the drinking habit to women. Drinking to excess is as common now among middle-class women as it used to be among washerwomen, cooks, and prostitutes; cirrhosis of the liver, it is stated, is now twice as frequent among female hospital patients in Paris as among male. The encouraging fact is noted that the drinking habit is becoming rare among the younger workmen, from 25 to 40 years of age; this is attributed to the growing love of sports, and to better conditions in the home. The peasant, owing perhaps to the revival of the home manufacture of brandy, does not show the same improvement. The report reviews the various measures which can be adopted for the reduction of alcoholism, from prohibition as practised in America to education and propaganda. Total prohibition is rejected as in itself worse than useless, and because in France,

the land of vineyards, it would be impossible. The recommendations of the report, unanimously adopted by the Académie, are: that laws promulgated against alcoholism during the war should remain in force; that the home manufacture of brandy should be suppressed; that the excise on alcoholic beverages, fermented and distilled, should be increased; that the use of "cocktails" should be regarded as dangerous to health; that regulations as to absinthe substitutes should be revised and enforced; that the number of wineshops should be limited; that temperance should be helped by the construction of healthy dwellings and the provision of popular resorts where only non-alcoholic beverages would be sold; that a law similar to that which has been successful in Norway and Belgium was desirable, prohibiting the sale by retail and the consumption in wineshops of beverages of greater alcoholic strength than 14 degrees, and the selling in grocers' shops of less than two litres; that the utilization of grapes and non-fermented grape juice for food, and of alcohol for industrial purposes, should be promoted; and that anti-alcoholic education and propaganda should be organized among all classes. At the meeting of the Académie on June 29th Dr. M. Letulle made a spirited attack on *apéritifs*, which he described as "infernal drugs" and classed with the medicated wines (as he said, *horresco referens*) with which in his youth the venerable family doctor used to torture his stomach.

#### REGIONAL TOWN PLANNING.

SINCE the Town Planning Act came into force in 1919 thirty-seven joint town planning committees have been formed; they cover an area of nearly six million acres. The matter is specially urgent in respect of London, which is now extending at a surprising rate to the west and north-west into Berkshire and Buckinghamshire. At a meeting at Wycombe last March the Council of the Institution of Municipal and County Engineers discussed the desirability of bringing to the notice of the local authorities of the South Bucks and Thames-side region the importance of regional planning. The district is a countryside of rare beauty crossed by the Chiltern Hills; it contains the Royal Castle of Windsor and some of the loveliest reaches of the Thames. Extensive industrial developments are, however, taking place especially at Slough in the vicinity of Eton College and Windsor Castle, and the area generally is becoming almost metropolitan. The outward spread from London and increased facilities of communication, including electrification of railways, tend to foster building development. Recently the local authorities concerned met to discuss the matter, and most of them decided to form a joint town planning committee. Most of the councils which have taken up town planning, being urban districts with a population less than 20,000 or rural districts, are not under any legal compulsion to interest themselves in the matter. Piecemeal development tends to lead a council into large expenditure, joint development allows grouped communities to arrange economical public services and communications, the countryside is not destroyed, the restfulness of country life remains, and efficient local government is ensured. No large expenditure on public works is necessarily involved; the present aim should be to prepare an attractive programme of developments which would place a definite aim before the public. In joint town planning areas (perhaps better named regional areas), especially those near large and spreading centres of population, the reservation of tracts of country for growing fresh food (vegetables in particular and also for dairying) must be considered. When studying the area such items as surface geology should receive attention so that this factor is given due weight when the allocation of the different

parts of the area for different purposes is being considered. Healthy sites should be reserved for housing, stable soils for heavy industries, fertile soils for cultivation, mineral deposits for exploitation. It would seem somewhat unfortunate that the medical aspects of town planning do not seem always to be sufficiently recognized; county medical officers are not invariably invited to such meetings. Some county councils consider that they should be given powers in connexion with such regional planning; at present they afford voluntary help—for example, the county surveyor often works out a survey designed to assist in the delimitation of all future building lines on county roads. But these are details; the main point is that there is reason for hoping that the England of the future, although a more urbanized England, will still retain some of its pristine beauty, even in the vicinity of large towns.

#### THE SALMONELLA GROUP OF FOOD POISONING BACILLI.

THE importance of the *Salmonella* group of bacteria in causing food poisoning has led to careful study of its various types which can, for the most part, only be distinguished from each other by serological tests. An attempt to co-ordinate the terminology of this group was made by Mr. T. Bruce White, and his conclusions were published last year in the Medical Research Council Report, No. 91 (JOURNAL, 1925, vol. i, p. 373). He has since been engaged in studying the antigenic modifications associated with "rough" variations in this group, and in attempting to determine the relative antigenic constitutions of several old and new *Salmonella* types. The results of his work are collected in No. 103 of the Special Report Series of the Medical Research Council.<sup>1</sup> He now suggests that three classes of this group of organisms are distinguishable—namely, the meta-*Salmonella* types, a monophasic, and a diaphasic type, and that the Aerttrycke type occupies a central and primitive position in the group. Data on which his conclusions are based are presented in detail, and the present publication, which should be read as a sequel to his previous report, appears to be a useful step forward in defining the mutual relations of the members of a hitherto confusing group of micro-organisms.

#### UVEO-PAROTITIC PARALYSIS.

DR. GEORGE PARKER of Bristol<sup>2</sup> has collected and tabulated sixteen cases of a rare syndrome, uveo-parotitic paralysis, which is characterized by inflammation of the uveal tract, parotid swelling, facial paralysis and often paresis of various muscles, multiple neuritis, and an erythematous rash on the legs and trunk, with or without fever. It appears that three cases have occurred within recent years in the Bristol district. Before 1909, when Heerfordt first described the syndrome on the basis of three cases at Copenhagen, the condition was regarded as an aberrant form of mumps, and some writers are of the same opinion still; but in none of the collected examples was there any connexion with cases of that disease. Bacteriology has so far failed to reveal the underlying infection, so that an absolute decision can hardly be reached at present; the suggestion that it is a deficiency disease has even been made. The average age of onset is 31 years, and females are more often attacked than males, thus contrasting with the incidence of mumps. The blood has been found to show a leucopenia instead of the lymphocytosis in mumps, but, on the other hand, the cerebro-spinal fluid has shown some lymphocytosis. Both parotids are generally affected,

and as a rule there is double but asymmetrical facial paralysis. The order in which the symptoms appear and their duration show much variation; in one instance the parotid swelling persisted for two years. In addition to erythema, which may resemble erythema nodosum, there may be urticaria and oedema of the ankles, legs, and below the eyes. Occasionally other cranial nerves are affected. In the same number of the journal Miss B. Rogers and Dr. Bodman<sup>3</sup> report a fatal case of polyneuritis preceded by inflammation of the parotid, salivary, and mammary glands, which is included in Dr. Parker's collection but differs from most of the other cases in two important particulars—the absence of definite uveitis or irido-cyclitis and the presence of severe cerebral disorder, and the occurrence of cardiac failure. Dr. Parker has done the profession a service by subjecting this strange syndrome to so thorough a critical analysis.

#### THE PATHOLOGICAL MUSEUM AT NOTTINGHAM.

THE feature of this year's museum was the close collaboration between physician, surgeon, pathologist, and radiographer in the exhibition of specimens. It has always been taken for granted that a knowledge of pathology is essential to correct diagnosis, but seldom has this important truth been more clearly and forcibly presented. The collection consisted chiefly of exhibits by those responsible for demonstrations in illustration of their own topics. The president of the Pathological Section, Professor Sholto Douglas, contributed a number of organs from cases of leukaemia (which formed the subject of Friday morning's discussion) as well as a beautifully mounted series of tuberculous guinea-pigs, which he used to demonstrate the complete failure of diaplyte vaccine in the treatment and prevention of tuberculosis. The vaccine, made by Dreyer's method, was prepared from the same human strain of tubercle bacillus as that used for the inoculations. It was injected into different groups of guinea-pigs before inoculation, at the time of inoculation, and after infection with the tubercle bacillus. In no case had the vaccine the slightest effect in checking the disease. Interesting specimens of aneurysm, of lesions of gall bladder and intestines, and many others, also came from the Sheffield department. Mr. E. F. Finch (Sheffield) showed twelve specimens of portions of the stomach removed at operation, chiefly from cases of chronic ulcer. These formed the subject of his demonstration on examples of gastrectomy for gastric ulcer. Dr. H. Gleave (Sheffield) exhibited specimens, sections, and x-ray pictures from an important case of osteoclastoma (myeloid sarcoma) with pulmonary metastases, a most unusual development in tumours of this kind. Gynaecology was well represented in the museum. Of great interest were the endometriomata collected by Dr. W. W. King, also of Sheffield. Beside them were some beautiful specimens and slides of chorionic carcinomata from a vesicular mole and from a testicular tumour, shown by Dr. W. D. Newcomb of St. Mary's Hospital. An exhibit which attracted a great deal of attention was the series of pituitary tumours from the National Hospital, Queen Square, demonstrated by Dr. Macdonald Critchley. They comprised a great variety of cysts and tumours, including an adamantinoma, and showed clearly the relation between the position of the growth and the patient's symptoms. Dr. Strickland Goodall of the Heart Hospital, London, exhibited some very interesting drawings and slides of thyrotoxic myocarditis, electrocardiograms showing the mode of action of the heart in anginal attacks, and a series of "broken hearts"—that is, rupture of the heart from various causes. In the tropical disease

<sup>3</sup> Rogers, B., and Bodman, J. H.: *Ibid.*, 84-90.

section was a collection of photographs of jaws in all stages, showing some very unusual lesions. The pictures were taken in the South Pacific by Dr. P. A. Buxton. The subject of basal metabolism was treated by Dr. E. G. B. Calvert, who gave a demonstration on Tuesday afternoon. A number of slides of a supposed cancer-producing organism were on view, but, unfortunately, none of the lesions caused by these organisms were presented. The Museum was a striking testimony to the ever-increasing importance of x rays in medicine, surgery, and pathology. Mr. A. H. Simpson of University College, Nottingham, a pioneer worker in 1895, showed a number of his early plates and photographs, and gave an interesting description of his experiences. In 1895 they happened to have in the department of physics a tube with a high vacuum, which had been made for Professor Crookes. With this they attempted to repeat Röntgen's work. They only had a 5-inch induction coil; there was no target, and the cathode rays went on to the whole side of the tube. Hence it was not possible to take sharp pictures. They worked with very slow photographic emulsions. In taking a picture of the hip-joint they had to use an exposure of forty-five minutes. Later they had a more powerful coil, but even then the exposure for a hand or foot was five minutes. Many children were brought to him for foreign bodies in the larynx or oesophagus, and he was usually successful in finding and removing them. The x ray was a popular amusement for nurses and parents, and for their entertainment he would show them the bones of his hands. The result was that all his nails came off. To protect himself he had a pair of chain-mail gloves made. Nevertheless he was still suffering from dermatitis contracted twenty-five years ago. Fortunately it had gone no further, and he had found that when a patch of dermatitis occurred he could cure it by radium, and it would remain healed for about six months. In spite of the difficulties which had to be contended with, the pictures he showed of thirty years ago of bones and foreign bodies did not compare unfavourably with those produced in more modern times. He was, however, unable in those days to take pictures of soft parts. From 1895 to 1926 is a long stride, and the audience passed from Mr. Simpson's historical demonstration to that of Dr. A. Gurney Yates (Sheffield), who showed the latest method of diagnosis of spinal lesions by lipiodol. This preparation, an oil of black poppy, containing iodine, was heavy, opaque to x rays, and quite harmless when injected into the meninges. Professor Séquard of Paris had introduced the method for the localization of lesions blocking the spinal theca. The lipiodol was introduced by cisternal puncture, and the patient x-rayed as soon as possible afterwards. If no obstruction was present the lipiodol collected almost at once at the lower end of the theca. In cases of obstruction, such as tumour, adhesions, or thickening of the meninges, the lipiodol accumulated at the level of the lesion. In partial obstruction the lipiodol would be held up for a greater or lesser time, and the x-ray examination might show some of the substance above and some below the block. In pictures from a case of meningitis there was a curious network of the substance which had been caught up and entangled in the numerous adhesions. Advances in radiography of the central nervous system were also shown by Mr. A. P. Bertwistle in his demonstration of cerebral localization by x rays. The contribution of radiography to diagnosis and pathology was likewise a prominent feature of the admirable collection from the Brompton Hospital, a collection consisting of specimens of different types of chest disease with x-ray photographs both with and without injection of lipiodol into the bronchial tubes. The cases of bronchiectasis, in particular, were most instructive.

Dr. Killian Clarke, Dr. Lane, and Dr. Bywater deserve the warmest congratulations on the success of the museum for which they were responsible.

#### THE "CRIPPLES' JOURNAL."

THE appearance of the July number of the quarterly known as the *Cripples' Journal* marks what should prove to be an important stage in its development and consequent usefulness, for it is its first issue as the organ of the Central Committee for the Care of Cripples. The journal was started two years ago and published by the Shropshire Orthopaedic Hospital at Oswestry, but, as stated in the April number, the management took the enlightened view that its usefulness to the cripple would be much increased if it ceased to be identified with one hospital and were made representative of all the activities and influences which serve the cause throughout the country. It has therefore been handed over to the Central Committee with a generous donation towards its development, and now appears with the committee's imprint and that of Messrs. John Bale, Sons and Danielsson, Ltd. It should have a prosperous career, for if it keeps up the literary and scientific standard of the past two years it will deserve success. In this number the editorial by Mr. G. R. Girdlestone on the work of the committee reinforces the appeal which he made in his Scheme for the Care and Cure of Crippled Children. Messages of encouragement are printed from, among others, Dr. Murk Jansen of Leyden, Mr. J. St. Loe Strachey, the Duchess of Atholl, M.P., and Sir Robert Jones. Dr. Murk Jansen contributes a suggestive article in which he lays stress on the physical deterioration of the Dutch people, and states that the consumption of tobacco in Holland per head has trebled in the last fifty years, and is now eight times as great as that of the average European. Although he refrains from drawing any conclusion from these facts, without further study, the significance of his figures may be realized when we read in another article in the same issue that in our own country 128,000,000 lb. of tobacco are consumed every year. Professor Edward Mellanby contributes an excellent article on the cause of rickets as revealed by experiment. Miss E. Storr tells a moving story of orthopaedic work in northern Newfoundland and Labrador with which the name of Dr. W. T. Grenfell must always be associated. Miss Maude Royden writes from the point of view of a cripple herself, and condemns—in her own case—all mechanical help, not because of any inefficiency, but for aesthetic reasons and because of its "branding into my perpetual consciousness the fact of my lameness!" Happily, all cripples are not so sensitive. Many other articles and paragraphs help to make up a most interesting number.

#### CLINICAL MEDICINE IN NORTH AMERICA.

IN the current number of *St. Bartholomew's Hospital Reports* Professor F. R. Fraser publishes his report to the Rockefeller Foundation on the teaching of clinical medicine in medical schools in America after his visit in the spring of 1925 to fifteen of these medical schools.<sup>1</sup> Interesting throughout, special attention is naturally attracted to the description of the differences between the American and the British arrangements and methods of instruction, which provides material for consideration of any possible improvements that may be made in our routine. Since Abraham Flexner's report to the Carnegie Foundation on "Medical Education in the United States and Canada" (1910) the number of medical schools in America has diminished by the elimination of the least fit, and there now are more candidates than the better schools can admit. Some schools select a comparatively small

<sup>1</sup> Fraser, F. R.: *St. Bartholomew's Hosp. Rep.*, 1926, lix, 35-47.

proportion of the yearly applicants, and when dealing with a large field are thus able to obtain a select student body of high intellectual attainments; medical schools of this calibre, such as Cornell, Harvard, Johns Hopkins, and Washington University in St. Louis, would tend to produce the type of logical, thoughtful researcher or teacher, who, when *in statu pupillari*, need opportunities and guidance rather than the amount of teaching that students of a more moderate mentality need to make them efficient. Medical schools able to accommodate large numbers and without excessive lists of applicants are more concerned to reject the unsuitable than to be exclusive, and as a result the intellectual level of their students will vary enormously, and the teaching required will on the whole be that necessary to breed the sound, steady practitioners so essential for the efficient service of the public; these conditions were noted at McGill (Montreal), Toronto, and Pennsylvania University (Philadelphia). The circumstances of the American schools as regards the selection of applicants are not familiar in this country, and Professor Fraser, of course, does not draw the fairly obvious moral lesson that, although no medical school in Britain can consist solely of the select intellectual students, the professorial unit, like an *imperium in imperio*, provides the appropriate milieu for the manufacture of original workers and the future teachers of medical students. It is perhaps well to recall this function of the medical unit, as there is a danger that it may be rendered difficult by an undue burden of elementary teaching. In some American schools the teaching of anatomy and physiology is compressed into a comparatively short period and is specially correlated with the actual needs of clinical work, and indeed supplemented by demonstration of patients. This may help to solve the difficulties presented by the ever-progressive overcrowding of the curriculum, especially in the case of the student of mediocre ability, but from an educational point of view, particularly for the abler students, it is not without disadvantage. In general the clinical tradition of British organization is imperfectly developed in America; students seldom act as clerks in the general medical wards for more than six weeks, but this is to some extent compensated by the almost universal practice of holding an internship. While clerking the American as compared with the British student is more highly cultivated, in that he is in the way of being encouraged to do original research and undertake some literary investigation bearing on his cases; but this is open to the danger of trying to teach the average student to run before he can walk. On the other hand, this method would, of course, be well suited for the select intellectual students after a full course of clinical clerking such as they get in Britain. That a house appointment should be part of the training of every qualified man is, of course, highly desirable, but it is difficult to see how in our existing conditions this can at present be attained. Professor Fraser touches with wise discretion on the subject of the full-time clinical teacher; he regards a clinical department controlled entirely by a full-time head as suitable for a school with a select student body of high intellectual level, but not for a school with a large number of students destined in the main for general practice. Further, in a big school with a large department of medicine there is the risk that a whole-time director may get so overwhelmed with administrative duties and details that he will become little more than a dean. The desirability of full-time clinical teachers in certain circumstances no longer admits of doubt, but the conditions under which they are established obviously demand careful arrangement and regulation. This well considered report closes with the definite pronouncement that no school can be regarded as offering an efficient up-to-date education unless it includes full-time laboratory-trained clinicians on its teaching staff.

#### MEDICAL UNDERGRADUATES' TRANSATLANTIC TOUR.

THE members of the Cambridge Medical Society, composed of the medical undergraduates of the University, are this month to visit the universities and medical schools of Canada and the United States. The party will leave Liverpool on August 13th. An enterprise of this kind, we believe, has not previously been undertaken by students of medicine in this country, and the fact that some seventy-five undergraduates have promised to take part in the tour points to the enthusiasm which is essential for success. All international meetings must be good in principle, since they show those taking part something of the problems and difficulties with which other nations have to deal. In science experience has shown that such meetings make entirely for good, but in no science can greater benefits be derived than in that of medicine. The members taking part in the present tour cannot fail to see something of the opportunities afforded for medical work, the nature of the clinics and laboratories, and of the advantages and disadvantages of medicine as a career in America. It is hoped that this tour may be the beginning of a wider movement and that the present visit may be returned from time to time by students from across the Atlantic. The present movement has been initiated and organized entirely by the undergraduates themselves, and they will be accompanied by no senior men. In Canada and the United States the proposed visit has met with general approval, and not only has a cordial welcome been extended by the universities, but most generous hospitality is being offered. The party will visit Quebec, Montreal, Kingston, Toronto, Niagara, Buffalo, Washington, Baltimore (Johns Hopkins), Philadelphia, Newhaven (Yale), New York, Boston (Harvard), where three days will be spent, and from whence the journey home will be begun on September 21st. The Cunard Company has made special arrangements, and inclusive fares which will not exceed £50 for the round tour. With expenses of food and board where necessary the total outlay for each member should not exceed £60.

#### POISONS AND PHARMACY ACTS.

THE Lord President of the Council has appointed a committee consisting of Mr. E. A. Mitchell-Innes, K.C. (chairman), Mr. I. G. Brock, Sir Malcolm Delevingne, Mr. F. W. Gamble, Sir William Graham-Harrison, Sir Donald MacAlister, Bt., M.D., Mr. E. T. Neathercoat, Mr. Colin Smith, Mr. G. Stubbs, Sir William H. Wilcox, M.D., and Mr. A. E. Young, to consider and report whether any modifications are necessary or desirable in the Poisons and Pharmacy Acts—(1) in regard to the conditions relating to the sale of poisons; (2) in regard to the procedure for the modification or extension of the schedule of poisons to which the Acts apply; (3) in the system of making and enforcing regulations in regard to the keeping, selling, and dispensing of poisons; (4) in regard to the central authority for the purposes of the Acts; and (5) in regard to any other matters to which the attention of the Committee may be drawn. The Committee has decided to take evidence on matters within its terms of reference, and any person, association, or firm wishing to give evidence or place their views before the Committee should communicate with Mr. M. D. Perrins, Home Office, Whitehall, S.W.1. The Committee will enquire generally into the existing machinery regulating the sale (retail and wholesale), keeping, distribution, and supply of poisons; any consideration of proposals for the inclusion in or exclusion from the schedule of poisons of any specific substance is *not* held to fall within the Committee's terms of reference. Mr. M. D. Perrins (Home Office) and Dr. E. W. Adams (Ministry of Health) are Joint Secretaries to the Committee.

## Nova et Vetera.

### WEST AFRICA AND ITS DISEASES A CENTURY AGO.

HUNDRED years ago Sierra Leone was reputed "the white man's grave," and I had always wondered about its health conditions; a century-old account of the climatic diseases of West Africa, by James Boyle, M.C.S.L., Colonial Surgeon to Sierra Leone, in the library of the Royal United Service Institution, "presented by the author," therefore promised welcome explanation. It is an octavo of some 450 pages, published in London in 1831. The author joined the navy in 1813 as an assistant surgeon, was promoted surgeon in 1820, and served till 1835, when his name disappears from the Navy Lists. During his time he served in the East and West Indies, and afterwards (1822-24) in H.M.S. *Cyrene* on the West coast of Africa, so that he had a large experience of tropical climates and diseases when he became Colonial Surgeon to Sierra Leone in 1827; he continued there till 1831. He was the author of several other medical works, and it is of interest to examine how the diseases of that time and place appeared to this industrious and experienced medical officer, what objective medical facts he reported, and what ideas emerge of the current illnesses and the causes of a mortality so excessive as to give the West Coast of Africa that terrible reputation, particularly as he prides himself that his is the first book ever published on the diseases of that coast. In the following account of Sierra Leone and its diseases the author's phraseology has been largely adopted.

As to statistics, he states that in three years (1819-21) the number of white men who arrived for the first time was 19, and that 7 of them (37 per cent.) died in their first year; of the general white population, then averaging 10, 5 (12 per cent.) died in each of those years. In 1824 the soldiers who arrived numbered 300, and from April to the end of the year, out of an average strength of 65 whites, 211 (45 per cent.) died of fever. In 1830 Freetown had 120 white and 25,000 native inhabitants. In 1824 there were 600 white civilians, of whom only 1 (0.8 per cent.) died, so that the picture has completely changed. Between 1827 and 1831 inclusive the navy on the station lost 20 per cent. its crews.<sup>2</sup>

Sierra Leone, Boyle says, is a lovely place on a fine day. Freetown has wide, well cambered streets, with two-storied houses for Europeans, and a fine mountain behind. Even the pestilent Bullom shore, seven miles off to the north-east, covered with bush, looks beautiful in fine weather. That shore is marshy, and generally to windward. In the dry season the dry Harmattan wind brings from it much dust; in the rains (April to October) the tornadoes bring over malaria and the poison of yellow fever.

The chief disease of the country, according to Boyle, is the bilious remittent fever, caused by malaria, the result of exhalations from decaying vegetable or animal matter. The climate, too, has an intrinsic quality that makes it deadly. Sol-lunar influence, besides, is powerful in the production of fever. In the sun, men suddenly drop down dead; while men who sleep on the upper deck, exposing themselves to the apparently harmless beams of a brilliant moon, have often been known to be affected suddenly with fevers—too suddenly for this to be ascribed to damp or falling dew. But some diseases (undescribed) are due to overcrowding, and are unfairly credited to the climate. Hepatitis and its sequel dysentery are mainly due to bad drinking water. To improve health, the bush should be thoroughly cleared, the area burned over, the ground drained, and the pools filled. The extension of towns and spread of agriculture always lessen malaria, and may even change the type of fever. (This statement may be compared with the views expressed by Sir Malcolm Watson in his *Malaria in the Federated Malay States*.)

The important diseases are fevers and hepatitis (which includes dysentery), and there is also guinea-worm.

Diseases now thought serious—pneumonia, diarrhoea, small-pox, and tetanus—have but the briefest mention.

The characteristic disease is the bilious remittent fever, which may be climatorial, endemic, or irregular; the forms are clinically very similar, and only to be distinguished by the history. Climatorial fever only occurs on board ships; once a person has gone ashore the next to attack him is the local or endemic bilious remittent, which does not recur; later fevers are the irregular forms. This is important as a guide to treatment. There are also the intermittent fever, or ague, with its characteristic stages, and the epidemic fever known as yellow fever, which comes in bursts and is very deadly.

The climatorial remittent fever, Boyle says, begins with chilliness and loss of appetite, severe headache, epigastrio pain, constipation, great heat of skin, suffused eyes, pains in the joints, pulse 90 to 140. As regards treatment, blood-letting to 30 oz. is generally necessary—it lessens headache and brings the pulse down; purging is needed, and mercurials are always exhibited. After recovery cinchona should be given. Prevention on board also was necessary; drunkenness should be done away with, and cleanliness, dryness, and ventilation by ports, scuttles, and windsails secured. Brodie's swinging stoves should be used to dry the air, especially after washing decks.<sup>3</sup> In my opinion this is a very good account of the "disease of overcrowding of ships," on which, as a result of experiences at Malta and Zanzibar, I read a paper to the Epidemiological Section on March 26th, 1909<sup>4</sup>; certainly the symptoms and the methods of prevention are the same.

The local or endemic bilious remittent fever is characterized by the vomiting of bile. It occurs chiefly at the beginning and end of the rains. Exciting causes are intemperance, extreme abstinence, fear, and sexual over-indulgence. The symptoms are just those already stated, but it is often preceded by an aguish rigor. Bad cases may become intensified into sporadic cases of the epidemic fever; recovery is often followed by ague. In this type of fever blood-letting does harm and makes convalescence tedious. The blood neither buffs nor cups [polymorphopenia]. The routine treatment is with mercurials, to set up salivation—calomel in 20-grain doses, perhaps every two hours. Above all things, says Boyle, do not move the patient, and beware of collapse; he himself, in collapse, was once declared dead by his medical friends—hence this warning. Apart from clearing the bush, prevention deals only with the avoidance of intoxication. The disease is seated in the stomach, which is always inflamed *post mortem*. Attention is not directed to the spleen, constantly reported enlarged. The irregular bilious fever is a mild remittent; besides there is ague. Blood-letting should not be done for either; for ague, quinine should be given up to 20 grains a day.

There were only occasional outbreaks of the epidemic or yellow fever—in 1823 and 1829, for example. In May and June, 1829, there were 34 cases, of whom 25 died; of 8 with black vomit, 7 died. These last were all in houses on the front, exposed to the wind from the Bullom shore. One victim had survived for twenty years in the colony.

The other great disease of the district is hepatitis; this, says Boyle, is rare in Sierra Leone (except imported), as the water is good; it is common on the Gold Coast, as the water is bad. The symptoms are frequent hard pulse, acute pain in the right side and at the top of the right shoulder. Treatment is by free bleeding and mercurial purges; if these do not relieve the pain, renewed bleeding, or leeches, and blisters. If pain disappears during the acute stage the patient may be poulticed. As to dysentery, its principal cause is drinking bad water, at least indirectly, for it is the liver that is attacked first. In treating this disease, bleeding is discouraged, but salivation is almost necessary. Of ipecacuanha there is no hint. Dysentery was a disease of the slaves in slave vessels, and the navy, which put crews aboard captured ships, suffered horribly. Our author reports some very successful operations, especially for shark bite.

<sup>3</sup> Compare "The Navy of To-day" (*Times*, March 5th, 1926; p. 15, last column): "sore throats are reduced by the application of heat to dry the damp decks after scrubbing."

<sup>4</sup> *Lancet*, 1909, 1, p. 1237.

<sup>2</sup> Annual Colonial Office Report.

<sup>3</sup> Admiralty Report on the Diseases of the African Station, 1847.

This book as a whole gives a picture of a good man struggling with puzzling adversity. There is no clear evidence of enteric fever, and his mysterious enemy was, clearly, mosquito-borne fever, malarial or yellow, and he suffered from one or both himself. The troubles of the climate and the local hardships were so severe that the added worry of mosquitos goes absolutely unmentioned. His efforts to discover the cause of these fevers was hampered by his not knowing that malarial fever had an incubation period of a fortnight, though he did observe that men who arrived in ships to load timber up the river did not develop fever for three weeks; the delay he ascribed to the preventive effect of the vigorous physical exertions required of them. He was observant in treatment, for he materially reduced his blood-letting as soon as he took duty on shore, though still giving heroic doses of mercurials. It is surprising to see how little confidence there was in quinine, probably because the current doses were too small. Intoxication is stressed as the cause of fever, but it could rarely be excluded. In those terrible times there was no other recreation. Housing, clothing, food, papers, books, lighting, clubs, cleared space for games, were little considered or were wanting. Officers had a little society, writes Mr. Whitelaw, Surgeon R.N., in 1823, but adds, "How many has care driven to the bottle," even among them.

This book is a monument of zeal and industry, not only at Sierra Leone but at home, where Sir William Burnett and Sir James McGrigor, the Directors-General of the two services, had put at Mr. Boyle's disposal their official information, of which, as his readers will see, he made good use.

W. E. HOME,  
Fleet Surgeon.

## HEALTH ADMINISTRATION IN AUSTRALIA

A ROYAL Commission was appointed in January, 1925, to report upon legislative and administrative changes which it might be advisable for the Commonwealth of Australia to make in conjunction with its constituent States. Its report was presented at the end of November last, and has now been printed. It shows that the Commission took evidence over a widefield from many representative persons, inspected sanatoriums, quarantine stations, and other health institutions, and held eighty-eight public sittings in twenty-two places. The recommendations deal with the general question of ill health in the Commonwealth; the co-ordination of its official medical services, both civil and military; co-operation between State and Commonwealth health departments; the prevention of the spread of disease, including venereal disease; the purity of food and drugs; maternity hygiene; child welfare; industrial hygiene; research work; and the relation of public health authorities to medical practitioners in regard to disease prevention, to voluntary agencies for the promotion of health, and to propaganda.

To investigate and determine the best methods for common action by the Commonwealth and the States in so many departments of activity was in itself a complex undertaking, which was not made simpler by the various geographical and administrative conditions in the great island continent which has a tropical climate in the north, where Cape York is within 11 degrees of the equator, and a temperate climate in the south. For administrative purposes it includes New Guinea and Norfolk Island. Its total area is close on 3,000,000 square miles. It is composed in the main of six States, ranging in area from Tasmania, with 26,215 square miles, to Western Australia, with 975,920. Each State has its own public health laws. In three States public health administration is under a board; in the remaining three there is a permanent official head. Local government has been developed and is operative in most places, though portions of Western Australia and New South Wales are still unorganized. The local authorities, such as the municipal or district councils, are the health authorities, though with varying powers in different areas. Some, for example, are water authorities; in other instances these duties are delegated to water boards; and in still other cases the public works depart-

ment both provides and manages the water supply. The Commissioners have rightly assumed on the part of their readers a knowledge of Australian affairs, and, omitting discursive writing, have limited themselves to those portions of the existing health legislation and administrative procedure which appeared to call for amendment. Their recommendations in general seem both fair and practicable, and they have clearly attempted to adapt their remedies to varying circumstances and conditions. In some cases direct control by the Commonwealth is advocated; in others co-ordination is suggested; and in others, again, where the administrative bond might perhaps prove irksome, co-operation is thought sufficient. It is recommended, for example, that the health of New Guinea should be under the direct control of the Commonwealth Health Department. Its coast is only some ten days' sail from Asiatic ports, from which small-pox might readily reach it, and endemic small-pox in New Guinea would threaten the whole Commonwealth of Australia.

In dealing with the medical services of the fighting forces the Commissioners are content with co-ordination. They advocate one director-general over all, but separate directors for the medical services of the navy, army, and air force, each with power to act independently when emergency arises. In civil administration the Commission would leave to the individual States their present autonomy in questions of health, but advises that the Commonwealth should lay down general principles for their guidance, and should employ the time-honoured reward of the grant-in-aid for those States which effectively conform. A State Council on health, with laboratory and other equipment, is recommended for each State. It should control all health activities within the State, including maternity and child welfare. There should also be, in the view of the Commission, a Federal Health Council for securing closer co-operation between the Commonwealth and State health authorities. On the State councils there should be representatives of the medical profession, and on the federal council, if the Government at any time thinks it would be an advantage, representatives nominated by the Federal Committee of the British Medical Association in Australia.

A feature of the report which is quite distinctive is the recognition by the Commissioners of the principle that a competent general practitioner service is essential to the efficiency of any system of health government. "Medical practitioners," they observe, "are among the first to come into relation with those who are affected with illness. They thus have the first and best opportunity of taking or advising steps for prevention." These observations of the Commission hold true even where the general practitioner is not a part of the health machine, for good medical practice is good preventive work, whether recognized by authority or not; if the doctor does not form a link in the health administration of his area many important services which he alone can render are obviously lost to the community.

The Commission notes that in February, 1925, the Federal Committee of the British Medical Association in Australia, to which reference has just been made, expressed the view that in no State of Australia "is the service of the practising practitioner officially utilized for the prevention of disease to any degree consistent with his knowledge and opportunity," and that "any scheme to rectify existing conditions must have as its immediate ideal the linking up of the general practitioner into active participation in the administrative scheme." The Federal Committee had further put forward an outline of the work the medical practitioner as a public servant should do, including sundry notifications, the ordering of disinfection, the control of contacts and carriers, and the medical inspection of school children. These suggestions the Commissioners adopt, and themselves recommend a model health scheme prescribing definite duties for practitioners. Pending the introduction of formal schemes they say that much could be done to bring doctors into the work by mutual agreement. There is a shortage in Australia generally of highly trained experts in public health. The Commission advises that steps should be taken to increase

the facilities for their training, and also to afford post-graduate instruction in health administration to prospective medical officers of health.

The matter of medical registration in Australia would also appear to need amending. Each of the six States is a registration authority, so that there are six Registration Acts and six registers. Medical qualifications differ in the various States, which is a source of confusion, and prevents the free transfer from one State to another of medical officers of the Commonwealth Health Department intended to be mobile. The Commission strongly urges that there should be one register, kept by one Commonwealth authority.

This report is framed on a broad plan. It is concerned with Commonwealth questions only, as affecting either the Commonwealth alone or the Commonwealth in its relation to States, for intra-State legislation and administration are not included in the remit. It should be of interest to every citizen of the Commonwealth who aspires to be a member of a vigorous race. It should be of interest also to every British subject in other quarters of the empire who wishes well to those of his own blood south of the line now seeking to evolve a co-ordinated health policy. The problem which the report endeavours to solve is one for which the genius of British peoples in the past has shown a certain aptitude. It is the problem of effecting control without tyranny, and of securing liberty which will not go on to licence. The report of the Commission should receive the attentive consideration of those with whom the decision will rest as to any legislative or other action requiring to be taken.

#### LEBANON HOSPITAL.

THE twenty-seventh annual meeting of the Lebanon Hospital for Mental Diseases, Asfuriyeh, near Beyrout, Syria, was held at the rooms of the Medical Society of London on June 1st; the chairman of the General Committee, Mr. E. W. G. MASTERMAN, F.R.C.S., presided.

This hospital has been under the direction of Dr. H. Watson-Smith, O.B.E., for the last seventeen years. During the past year 135 patients (83 men and 52 women) were admitted. From the previous year there remained 95 patients, making a total of 230 patients under care and treatment throughout the year. Of this number 33 (16 men and 17 women) were discharged completely recovered and enjoying full mental health; 37 (25 men and 12 women) were discharged improved, although the nature of their malady rendered it possible that they might relapse in the future; 15 men and 3 women were discharged not improved. Primitive methods of treatment in the form of exorcism are still much in use in Syria. Spells are still believed in. Chaining naked patients in damp caves and beating them with shoes to trample out the demons are still practised, and patients are still received who have had crosses and other devices cauterized on their heads by red-hot irons. Bleeding is commonly resorted to as a means of treatment.

The CHAIRMAN said that the number of women patients with acute symptoms was increasing, and single-room accommodation for them was becoming pressing. Such cases were unlikely to decrease during the present troublous times in Syria. The payments by the French Government for necessitous cases had fallen in value with the fall of the franc. Mr. Masterman paid a tribute to the valuable work of the Executive Committee in Beyrout.

Mr. W. A. ALBRIGHT, J.P., one of the trustees of the hospital, in moving the adoption of the report, referred to the healthy open-air life lived by the patients and to the cheerful atmosphere. Far more facilities for curative open-air occupation would be opened out when the land could be irrigated and brought under cultivation. Mr. F. HOURANI spoke of the great service of the hospital to the Syrian nation, and hoped that in course of time Syrians would take the burden of the work upon their own shoulders. Dr. J. F. WHITWELL presented the report of the medical director, which included statistical tables showing the prevalent forms of mental disorder in the East.

Dr. FORTESCUE FOX referred to Asfuriyeh as a centre of treatment, of teaching, and of research. The resident

fifth-year students to be supported by the Rockefeller Foundation would be of assistance to the director in his work as clinical professor of psychiatry in the American University of Beyrout. Mr. JOSEPH BUTLER, senior honorary treasurer, stated that over £4,000 a year was contributed in Syria itself on behalf of patients. Dr. PERCY SMITH mentioned that it was at Bethlem Hospital, London, that the General Committee first met. Dr. BEDFORD PIERCE moved a vote of thanks to auxiliary committees in America, Switzerland, and Holland.

Reports can be obtained from the general secretary, Miss Hilda Fox, at 67, High Street, Marylebone, W.1.

## Union of South Africa.

[FROM OUR CORRESPONDENT IN JOHANNESBURG.]

#### PLAGUE RESEARCH.

It was realized by 1924 that bubonic plague had spread very extensively amongst the wild rodents of the Union. The deaths reported from time to time, chiefly among native labourers on the veld, from what was proved by laboratory examination of the affected glands to be undoubted plague, began to cause public alarm, and towards the end of 1924 the Union Public Health Department made arrangements with the South African Institute for Medical Research in Johannesburg for establishing and carrying out a definite scheme of research into the whole problem. The Government and the Witwatersrand Native Labour Association have each contributed £2,500, to be devoted primarily to plague research in the Union; it is supplementary to their ordinary grants to the Institute for Medical Research. They have undertaken to continue an annual contribution of this amount for the next three years. Under this scheme a research bacteriologist and a research entomologist have been appointed; and a mobile field laboratory was organized with the institute at Johannesburg as a base. The research bacteriologist is Dr. Pirie, formerly Government bacteriologist at Nairobi in Kenya Colony, and since 1918 in charge of the routine division of the South African Institute for Medical Research. Dr. A. Ingram, previously director of the Medical Research Institute at Accra, Gold Coast, is the entomologist. These officers have been working on this scheme since the beginning of last year. Comprehensive and detailed reports of their investigations are now being prepared by the South African Institute, but meanwhile short interim reports have appeared. Their investigations establish beyond doubt the fact that the disease of veld rodents is indeed the disease which is called plague in human beings. As was pointed out in a previous letter, doubt has been expressed in certain lay quarters, and the Minister of Public Health was carefully questioned on this matter in the House of Parliament. It was feared at the time that the prominence given in the lay press to these expressions of doubt might seriously discourage the efforts by private individuals in rodent destruction. Authoritative statements were made to combat these questionings; but perhaps the most effective stimulus to renewed activity in rodent destruction was provided by some unexpected deaths from plague in the Calvinia district of the Cape. These cases occurred at a point over two hundred miles south of the area in which plague had previously been known to be enzootic among veld rodents.

The animals which have during the past few years been reported as suffering a fairly high mortality from plague are: the common (lobengula) gerbille, multimammate mouse, long-eared mouse, Eastern Karroo rat, ground squirrel, spring hare, and yellow mongoose. All these animals have now been tested experimentally as to their susceptibility to plague. The workers express the opinion that all the veld rodents are more susceptible than the common black rat. The black rats do not belong to South Africa; all three varieties were originally imported by shipping, and they continue to be so imported; of the rats in South Africa they are much the most domesticated, and are usually the only ones found in and about human

habitations. Even these rats sometimes become "wild"; thus in Natal it has been observed that they have taken to the bush near Durban, where they live in hollow trees. The domestic rat being the least susceptible of our rats, all our rodents must be regarded as potential agents in the spread and propagation of plague. But the only animals of practical importance appear to be, on the high veld, the gerbille, multimammate mouse, and ground squirrel; and on the lower, more bushy country, the striped mouse. The Karroo rat, though very abundant and experimentally apparently the most susceptible of all animals yet examined, is not an important agent in the spread of the disease. It appears to escape almost entirely when an epizootic has been raging amongst gerbilles living in close contiguity; this is attributed to the fact that its flea parasites are peculiar to itself—it has none in common with the gerbilles. Spring hares, which have been known to travel as much as twenty miles in a night, and might, therefore, be expected to be capable of causing a rapid spread of the disease, are also excluded as the result of experience. They, too, have their own private set of flea parasites.

Two carnivores, the suricat and the yellow mongoose, have been studied. They live in close relationship with some of the rodents, and have in the past been reported as dying in considerable numbers in the wake of a plague epizootic amongst rodents. Small rodents form part of their normal dietary, and large numbers are probably eaten when they are sick or dying and can easily be caught; at such times the dung of these animals is thick with rodent fur. Experimentally the suricat is easily infected with plague, whereas it has been found impossible to infect or kill a mongoose, even when extreme doses have been employed. One captive mongoose ate four whole carcasses of gerbilles dead of plague, yet did not subsequently show the slightest sign of illness. It is proposed to exploit this insusceptibility of the mongoose to plague in rodent destruction, and to this end Dr. Pirie recommends that it be protected.

Bacteriological investigations have been carried on in many directions. An interesting question is whether there are within the species *B. pestis* serologically distinct groups. Nine South African strains, two from rodents and seven from human beings, were closely studied, and compared with eleven human and two rat strains from Bombay, and five human strains from Ceylon, a Japanese ship which arrived at the Cape with plague patients on board, Manchuria, and Nairobi respectively. Microscopically and culturally all these strains had the characters of *B. pestis*. All the South African strains give the characteristic pathological picture of plague in animals that have been infected with them, and some of these strains are as virulent as any of the foreign strains. All the strains tested with antiplague serum were agglutinated, but to greatly varying degrees. In attempting to differentiate types among the various strains by the method of agglutinin absorption difficulties were met with, both in getting emulsions of *B. pestis* that were not auto-agglutinable, and in obtaining agglutinable serums of high titre. It is, however, hoped to overcome these difficulties.

Reference was made in my last letter (June 5th, p. 962) to the new disease of veld rodents, the so-called "Tiger River" disease. Experiments in the utilization of this virus (which appears to be harmless to man) in the campaign against veld rodents are being made on a large scale; there is considerable promise of success. The disease can be spread both by laying down infected food and by letting loose infected animals.

At the Cape Municipal Congress held at Kimberley recently Dr. J. A. Mitchell, Secretary for Public Health, addressed the delegates. Referring to plague, he drew attention to the Calvinia outbreak. Infection was known to exist in the Midlands and other parts of the Cape, but there was now danger through De Aar to the Calvinia area. The plague area was also within striking distance of the Far East Rand, and if plague became prevalent it would be impossible to prevent it spreading right along the Reef. The problem from the towns and urban areas point of view was to starve out rats. A campaign lasting only one or

two months simply left matters as they were. He was glad to say that in the greater part of the Union a continuous campaign was being maintained. In his annual report for the year ending June 30th, 1925, Dr. Mitchell gave the following plague figures for the Union: There were 55 outbreaks of the disease; the white cases numbered 22, with 8 deaths; native cases 90, with 60 deaths. The total number of cases was 112, and of deaths 68.

#### INVESTIGATION OF SOUTH AFRICAN REMEDIES.

An investigation of considerable magnitude, and one which is of very great interest to South Africa, is at present being carried on in the department of pharmacology of the University of the Witwatersrand by Professor J. M. Watt, head of the department, and his assistant, Miss Marie G. Brandwijk. These two investigators are making a complete survey of the present position with regard to "huismiddels" (Dutch household remedies) and native medicines. Very many of these remedies are still apparently in constant use among Europeans. Many plants and parts of animals are in demand among natives, and form the main stock-in-trade of the reputable herbalist as opposed to the filthy witch-doctor. In the past scientific investigation of these popular remedies, European and native, has been of a desultory and haphazard nature. Isolated references to them are of fairly frequent occurrence in the scientific and medical literature of the country, but these are so scattered as to be practically inaccessible to investigators. Often the plant whose virtues are described is too inadequately indicated to make botanical identification possible. Some of these remedies are being brought actively to the notice of the public by being commercially exploited, too often without any real foundation for the claims made. Such a state of affairs is manifestly unsatisfactory, and a very real service will be rendered by the present investigators if they are able to place on record the present state of our knowledge of these remedies in a form which will be easily available for reference. It is also hoped that such a record will form a basis for further investigation of those substances which appear likely to be of value in medicine. The research is receiving the active support of Government departments, particularly the Department of Native Affairs, the Division of Botany, and the Forest Department. The Department of Bantu Studies of the University is also interesting itself in the matter.

#### UNIVERSITY DENTAL CLINIC.

The following have been appointed senior honorary visiting surgeons to the dental clinic of the University of the Witwatersrand: A. H. Ackerman, D.D.S. Michigan. M. L. Arenson, D.M.D. Harvard, J. H. Brever, Tandanus (Holland), B. J. Eccles, L.D.S., M.R.C.S. Eng., G. A. Forsyth, D.D.S. Pennsylvania. These appointments increase the staff of the clinic to twenty. This dental clinic was started some years ago as a charitable organization to meet the great dental needs of the poor in this town by the Johannesburg Dental Society. It was housed from the beginning in the building which had been erected by the Joint Council of the South African Red Cross Society and the Order of St. John for treating diseases of the chest. The sum of £40,000 had been given at the end of the war by the Joint Council of the British Red Cross Society and the Order of St. John to Lord Buxton, then Governor-General of the Union, who handed it over to the Joint Council of the two bodies which was formed in South Africa. Of this sum the Joint Council of the two bodies in the Transvaal was given £10,000 with which to erect a building to house a clinic for diseases of the chest. This building was formally opened in 1922. The requirements of Johannesburg in the way of tuberculosis treatment proved to be entirely insufficient to justify so large and elaborate a building, and the "tuberculosis clinic" became in 1924 a "polyclinic" housing, in addition to the clinic for diseases of the chest, the out-patient clinic of the Transvaal Memorial Hospital for Children, and the clinic of the Johannesburg Dental Society. It very soon became apparent that the dental portion of this polyclinic was proving much the most important, and it has grown to

such proportions that at the beginning of the present year the whole building was handed over to the University of the Witwatersrand on a ninety-nine years' free lease, to be used entirely for dental work.

Apart from its great value to the University as a training school for dental students this University clinic, as it is now called, provides a very necessary service to a community which includes a very large number of "poor whites," natives, Euraficans, and Malays, who are very liable to dental disease and who were previously almost entirely debarred from receiving treatment. An idea of its activities may be formed from its monthly returns. Thus during May there were 185 new patients, 355 old patients, 936 extractions, 10 fillings, 37 full dentures, 8 partial dentures, and 4 repairs. The clinic, as its name indicates, is now entirely controlled by the University, through a Dental Board which consists of the Principal of the University, the Dean of the Faculty of Medicine, two other members elected by the Faculty, and five members elected by the dental staff of the University. The Dental School is administered by the Faculty of Medicine of the University, dentistry being regarded as one of the special subjects rather than as a course entirely distinct from medicine. A five years' course leads to the B.D.S. degree, but the students are encouraged to take rather the combined medical and dental course of seven years leading to degrees in both medicine and dentistry. There are seven departments in the Dental School—namely, (1) conservation, (2) dental surgery and pathology, (3) prosthetics, (4) orthodontia, (5) dental diseases of children, (6) dental radiology, (7) dental anaesthetics.

#### THE MEDICAL SCHOOL OF THE UNIVERSITY OF THE WITWATERSRAND.

At the June examinations the following candidates were successful in all the subjects of the final professional examination for the degrees of M.B., Ch.B.: M. Chaitowitz, L. I. Cohen, H. Danchin, J. P. Grieve, A. L. Harington, H. Levy, J. Mazell, L. M. Rodger, H. Simon, J. Tasker, S. Verster, A. P. Vorster. With two exceptions all these medical graduates have been elected to house appointments in the Johannesburg General Hospital or its branches—maternity, children's, urological, or fever. This means that virtually the whole of the Johannesburg General Hospital and its various branches will have for its resident staff medical graduates of this University. The bursary which was founded in commemoration of the work of the late Anne Fenton Cleaver, sometime medical inspector of schools and director of the school clinic at Johannesburg, and which is given annually to the best woman student of the year in the subject of diseases of children, has been awarded to Miss Rachel Getz.

## England and Wales.

#### ROYAL NATIONAL HOSPITAL FOR CONSUMPTION.

THE Prince of Wales opened the new nurses' home at the Royal National Hospital for Consumption at Ventnor on July 22nd. The home, erected in memory of the late Mr. Thomas Lampard Green, is three stories high, and is connected with the hospital grounds by a subway. The ground floor includes sitting rooms and bedrooms for the matron and home sisters, writing, recreation, and dining rooms, and the kitchens. On the first floor are bed-sitting rooms for six sisters, and bedrooms for ten nurses. The second floor contains more bedrooms for nurses and maids, and a luggage lift is provided for each floor. The building is warmed by hot-water radiators, and there is a constant supply of hot water on all floors. Ground has been levelled to provide a tennis court, and on the south front of the building there is a long terrace overlooking the sea. The chairman of the board of management, Mr. P. B. Burgoyne, welcoming the Prince, stated that the hospital, which was founded in 1867, comprised now eleven blocks of buildings, with accommodation for 164 patients. During the last year 631 patients had received treatment, of whom 50 per cent. came from London and its neighbourhood. The

Prince, who is patron of the hospital, congratulated the board on the fact that in building the home no debt had been incurred. It is proposed to raise an endowment fund for the expenses of its upkeep.

#### METROPOLITAN HOSPITAL SUNDAY FUND.

At a meeting of the council of the Metropolitan Hospital Sunday Fund, on July 29th, under the presidency of the Lord Mayor, Sir George Makins, the chairman of the committee of distribution, stated that the collection was £4,600 below that of last year, and it was feared that when the final figures up to October 31st were obtained there would be manifest a decrease in church collections and donations. Members of the Church of Scotland, however, had contributed £959, as compared with £908 last year and £809 the year previously. The report showed that the total of the Fund on August 9th next would amount to £80,470. During the year 226 institutions had applied for grants, being one less than in 1925, and the committee had recommended a distribution of £80,005 to the various hospitals selected. Of the total sum available for distribution 7½ per cent. was appropriated for the purchase of surgical appliances during the ensuing year, and 2½ per cent. for district nursing associations. The principal awards to hospitals were as follows:

London Hospital, £7,100; St. George's £3,320; Hampstead and North-West London, £3,250; Middlesex (and Convalescent Home), £3,000; St. Thomas's £3,000; Royal Northern, £3,000; King's College, £2,150; Royal Free, £2,500; St. Mary's, £2,150; University College, £2,610; West London, £1,800; Westminster, £1,600; Seamen's, £1,300; Queen's for Children, £1,800; Hospital for Sick Children, Great Ormond Street, £1,500; Metropolitan, £1,320; Charing Cross, £1,625; Prince of Wales's, Tottenham, £1,500; Queen Mary's, West Ham, £1,200; City of London Chest Hospital, £1,140; Brompton Hospital, £1,100; East London, £1,100; Victoria Hospital for Children, £1,050; Royal National Orthopaedic, £1,100.

#### DUST AND SMOKE NUISANCE IN LONDON.

The London County Council proposes to promote legislation next session to enable it to make by-laws dealing with the nuisance arising from dust during the demolition of buildings. Some part of London is always in the hands of the housebreaker, and the dust and particles of lime which arise when the walls and ceilings are brought down and the debris is carted away can be very distressing. As long ago as 1900 a conference called by the London County Council passed a resolution calling upon owners or contractors when demolishing buildings to prevent annoyance as far as possible by sprinkling water and erecting reed or straw screens. The Home Secretary of that time expressed doubt as to the efficacy of a proposed by-law, and the matter was not proceeded with. But in the City of London the corporation has for some years past had a by-law requiring the placing of screens or mats around the property and the use of water, and this is said to have been effective. The London County Council has also agreed to make an annual contribution of £100 for three years towards the cost of certain investigations by a committee of the Department of Scientific and Industrial Research into atmospheric pollution and the cause of fogs. The work hitherto undertaken by the council in this matter has been limited to the maintaining of soot gauges in the parks and open spaces and analysis of the samples collected. The Department of Scientific and Industrial Research has offered to accept responsibility for the organization of an inquiry, with the co-operation of the local authorities, and under certain conditions to make contributions equal to those made by the authorities. Birmingham has resolved to make an annual contribution of £50 on condition that six other large cities make the same contribution. The City of London has given £50, and other local authorities have given smaller sums.

#### DERBYSHIRE HOSPITAL FOR SICK CHILDREN.

By the provision of eleven additional beds at the Derbyshire Hospital for Sick Children the accommodation for patients has been increased to fifty-two, which, besides relieving the strain on the hospital, will allow the nurses in training there to become eligible for certificates. The isolation block presented by the late Sir Herbert Raphael

In 1906 has now been transformed into a single commodious ward, which was opened by Captain Drury-Lowe on July 8th. Sir Herbert Raphaël had presented the block during his year of office as president of the institution, with a view to its serving as an isolation department for the hospital. For a considerable time it fulfilled that purpose, but eventually treatment became available for such patients at the Borough Infectious Diseases Hospital. In addition to the eleven beds provided by the conversion of the block, some measure of accommodation for the extra nurses has also been obtained, and Mr. Alan Reid, chairman of the board of management of the hospital, announced that the cost of the alterations would be met out of revenue, and that no special appeal to the public in this connexion would be required. Captain Drury-Lowe, in opening the ward, said that the hospital was the only one of its kind in the county. Mr. F. H. Frere, chairman of the House Committee, stated that the hospital had been overcrowded for a considerable time; additional land had now been acquired, and it was hoped that building operations would be begun before long; the conversion of the isolation block would greatly ease matters in the meantime. The new ward is provided with a terrace for open-air treatment.

## Scotland.

### HEALTH OF GLASGOW.

THE report of the medical officer of health for Glasgow for 1925 has been issued by Dr. A. S. M. Macgregor, although it is pointed out that his predecessor, Dr. A. K. Chalmers, was still in office as medical officer of health during the first half of that year. The death rate of 13.97 per 1,000, it is pointed out, compared favourably with that of 15.39 for the preceding year, although it is not so low as in 1923 (13.66), which was the lowest recorded for the city. The births during 1925 numbered 25,416, compared with 25,330 in 1924. This was the first year in which an increase had occurred since the high post-war birth rate of 1920. High rates were recorded in the industrial and working-class wards, and low rates in the residential quarters, varying from 34 per 1,000 persons in Mile End Ward down to 7.8 in Kelvin-side and 9.9 in Cathcart.

**Causes of Death.**—The highest death rate was experienced in Mile End Ward (17.7), while that for Cathcart and Pollokshaws Wards was 9.5. The death rate from infectious diseases during 1925 was 1.24 per 1,000, which was the lowest recorded since 1921 and compared favourably with 1.71 in 1924. Malignant disease had been increasing over a considerable number of years, and during 1925 the number of deaths was 100 higher than in 1924. The deaths of children under 1 year of age numbered 2,591, compared with 3,005 in 1924, and the infant mortality rate was 102 per 1,000, compared with 119 in 1924 and 89 in 1923.

**Infectious Diseases.**—During 1925 the number of cases of puerperal fever notified was 300, compared with 239 during 1924. As in 1924 and 1923, no cases of typhus fever occurred, and the diminution in the number of cases of enteric fever continued. The number of new cases of pulmonary tuberculosis (1,600) was the lowest on record. The number of cases of scarlet fever was the highest since 1915. Encephalitis lethargica was contracted by 45 persons, of whom 26 died; the number of patients of all ages disabled as a result of the condition and its sequelae constituted a new administrative problem with important medical and social bearings, because many would require permanent institutional treatment. The number of persons in Glasgow showing definite disability as the result of this disease is estimated at about 200.

**Veneral Diseases.**—The number of new cases of venereal diseases was 5,187, which was a decline on the numbers of the previous years, although the total attendances increased, with an average of 25.6 for each patient. In 523 instances the disease was a reinfection. With regard to ophthalmia neonatorum, the case rate is at present less than 3 per 1,000 births. In 1921, when the rate was 6, the instillation of silver nitrate into the eyes of the newly born became compulsory on all midwives, and the

opinion is expressed that this has contributed to this favourable result.

**Housing.**—In the report of the previous year it had been estimated that in order to replace houses which ought to be demolished and to allow for deterioration of existing houses, as well as to provide for the natural increase of the population, some 5,000 houses annually would be required during the next twenty years. It appears from the present report that not more than one-third of this number is actually being provided. The Public Health Department had found on inquiry that a tendency is growing up among the occupants of new houses to take in lodgers or to sublet a room to other families. This, in some cases, produced overcrowding. It is suggested that, as the aim of rehousing schemes is the ensuring of healthy occupancy, the tenants should be subject to rules governing this. The clearance of back-lands is being gradually accomplished; down to 1919 143 had been demolished, but 591 still remained. By last year the number had been reduced to 450, and of these 50 are included in a clearance scheme. Some inquiry had been made into the view which has been held in regard to the slum dweller and his tendency to make a slum wherever he went into new houses. At Hamiltonhill a detailed survey was made of 347 houses provided for tenants dispossessed through slum clearance in the Cowcaddens area. Of the new houses 31 (9 per cent.) were found to be unsatisfactorily kept, being dirty and bug-ridden. On the other hand, 151 houses were clean and well kept, many of them models of cleanliness, while the remaining 165 were passably good. It is suggested that a probationary period might be arranged for tenants of this class before they are entrusted with new houses.

**Smoke Abatement.**—It is noted that some progress has been made in this direction along the lines of (1) extended use of electricity for power purposes; (2) the use of mechanical stokers and steam boilers; (3) the substitution of smokeless fuel in furnaces where mechanical heating is not suitable, and (4) the substitution of smokeless fuel for raw coal in household fires and boilers for central heating. The first practicable step to produce a smokeless fuel suitable for domestic purposes was taken by the corporation in 1925. The fuel, called "kincole," is found to produce more radiant heat than an equal weight of raw coal.

### EDINBURGH HOUSING SCHEME.

Edinburgh Corporation has made considerable progress in building houses on the new area in the Lochend district, in accordance with a scheme elaborated after the passing of the Housing Act of 1919. On July 26th the main thoroughfare, which is to be known as Sleigh Drive, was formally declared open by Lord Provost Sir William Sleigh, who planted a number of maple trees along its border. The scheme comprises 42 acres of ground and two miles of streets. In this area 32 demonstration blocks and 802 houses have been erected. Of the latter, 150 are of the two-roomed type suitable for persons of small means. A number of similar houses together with shops are still to be erected. At a luncheon in the City Chambers the Lord Provost cordially congratulated the Housing and Town Planning Committee on what it had achieved. With regard to the housing problem Edinburgh was now beginning to see daylight. The houses erected by the Corporation under the Housing Acts now numbered 4,560, exclusive of the steel houses which were being provided under Government auspices and also exclusive of the large number of houses which had been erected by the private enterprise with the help of the subsidy. The total capital expenditure on housing was over £2,000,000. When the Corporation purchased the Lochend estate three years ago, one of the criticisms from the financial point of view had been that a large part of the estate would lie idle for a long time before it could be developed. Within this short period, however, what was practically a new town had sprung up at Lochend and all the land allocated for housing had been taken up. Consequently yet another estate had been bought at Saughtonhall for similar development. Great appreciation had been expressed by some of the tenants who had been removed from slums to these new quarters. Councillor P. H. Allan

said that the number of houses erected in connexion with slum clearances was 814, and their provision had enabled the Corporation to proceed with slum clearances in the Cowgate, Grassmarket, and other areas; good progress was being made, although the problem was still acute. It was estimated that the present scheme of slum clearance would be completed in about twelve months and then other areas like St. Giles and the Canongate would be treated, so that the housing question must not be considered as by any means settled. It was an undoubted fact that the health of boys and girls removed from slum areas had greatly improved since they had been taken to Lochend, where they had fresh air and sunlight.

#### PNEUMONIA AND TUBERCULOSIS IN FARM LABOURERS.

Dr. Rae, chief medical officer of health for the county and burghs of Aberdeen, in his annual report described the farm servants in the county as an improvident class in health matters. In other classes cases of pneumonia were notified within two or three days, but the farm servant would toil on until the fourth or fifth day, and then, very often, collapse. Consequently the mortality from pneumonia amongst them was larger than in other classes of the community. Similarly with tuberculosis. From want of education or want of thought the farm hand failed to call in the doctor in time. Dr. Rae gave this explanation in reply to a member of his committee, who attributed the large incidence of tuberculosis amongst farm servants to their carelessness in not changing their clothing after it had been soaked with rain. Another member of the committee asked whether bad housing was the cause of the excess of tuberculosis; but Dr. Rae, while admitting that housing might be improved in some cases, said that he had not found the farm servants in Aberdeenshire worse off than those in other counties in Scotland.

#### DENTAL EDUCATION.

The prizes for the session 1925-26 of the Incorporated Edinburgh Dental Hospital and School were presented by Mr. J. W. Dowden, F.R.C.S. In the report on the work of the school the Dean, Mr. William Guy, F.R.C.S., said that the dentist's field of study was wider in extent even than that of the doctor, while in addition he had to acquire laboriously a great degree of mechanical dexterity. He found a somewhat grim satisfaction in the reflection that in their school the students must either work hard or go under, and there was no place for slackers. During the past year the school had been a little hampered by the building of the extension, but the work submitted for the work-room competitions had given proof of attainment by some pupils of a remarkable standard of craftsmanship. Competition had been keen in general and special classes, and medals had been hard to win. He had been glad also to observe that in the cult of athletic and other sports the school had many enthusiastic and some successful devotees. Mr. Dowden, in a short address, mentioned that it seemed a curious fact that at the present day so large a number of people lacked their own teeth. Whether that was due to hasty or varied diet he could not say. Many diseases were now claimed by physicians as being caused through the teeth, and he would call attention to the importance, not only of fact in dental work, but of imagination, for when dealing with human patients imagination must be given some sort of play. In addition the dentist's knowledge should be carefully systematized.

#### ROYAL (DICK) VETERINARY COLLEGE.

At the annual distribution of prizes at the Royal (Dick) Veterinary College, Edinburgh, Sir Thomas Hudson Beare, chairman of the board of management, said that the extension of post-graduate work was one of its chief aims. There was a great field for post-graduate work in veterinary science, and it benefited the men working for an ordinary diploma that they should be studying side by side with men engaged in original research and post-graduate work. One particular line of work which had been taken up by the instruction of the Board of Agriculture was the diagnosis of poultry disease, which was a matter of great practical value. He pleaded

for further help in the way of endowments, for the College was playing no small part in regard to what he held to be the chief industry of the country—agriculture. It was in particular urgent to develop the department of parasitology under a teacher of eminence who would give his whole energies to the work of research. The Earl of Stair, after presenting the prizes, remarked that veterinary science still needed to acquire much more knowledge, as the experience of the last year or two proved. Although the result of efforts against foot-and-mouth disease was not exactly a defeat, nothing less than a repulse had been encountered.

## Correspondence.

#### POST-GRADUATE HOSTEL, LONDON.

SIR,—There can be no doubt that a foregathering of medical post-graduates in London from a social point of view is just that link which has been wanting in most of the post-graduate efforts in the past. This defect has now been remedied, and the opening of the Post-Graduate Hostel at the Imperial Hotel, Russell Square, London, is most opportune, for many post-graduates will be sojourning in the metropolis during the summer and autumn months. The first informal talk and discussion on operations on the stomach was certainly a success, and those to follow should be well patronized.

I feel sure that the opportunity afforded, in the excellent room placed at the disposal of post-graduates by the management of the Imperial Hotel, of discussing topics taken in the post-graduate courses held in London by the post-graduates making this hotel their headquarters, cannot but bear most valuable fruit.

It would be a pity if a single post-graduate was to stay anywhere in London apart from his or her confreres who will be residing in the Hostel and making use of its facilities.—I am, etc.,

London, W.1, July 31st.

W. McADAM ECCLES.

#### "ATOPHAN DERIVATIVES IN RHEUMATISM."

SIR,—Dr. W. Langdon Brown, in his letter in your issue of July 3rd (p. 37), has done good service to the medical profession and to the public by calling attention to the possibility of the occurrence of toxic jaundice after the administration of atophan, atophanyl, and atoquinol. His experience has been confirmed by that of Dr. Geoffrey Evans and Dr. C. Worster-Drought in the communications in your issue of July 10th, and by that of Dr. Lewis G. Glover in his letter in the *JOURNAL* of July 17th.

I have no doubt as to the capacity of these preparations to produce in certain cases toxic jaundice. I have seen in consultation three cases of toxic jaundice following the administration of atophan in ordinary doses by the mouth, and I have no doubt that the jaundice was the direct result of the toxic action of atophan on the liver. One of these cases was fatal. The patient, a man of 69, in feeble health and suffering from chronic gout, was given atophan gr. v t.d.s. by mouth for one week, bicarbonate of soda 1/2 dr. in a tumblerful of water being taken night and morning. Deep jaundice developed a few days after the completion of this course, and death resulted twenty-eight days after the onset of "nal symptoms were those of icteru most of the icteric period the stools showing that the jaundice was not obstructive.

The toxic action on the liver of the preparations under consideration is probably due to the presence of the quinoline nucleus in each. Atoquinol can hardly be regarded as a derivative of atophan, but both are derivatives of quinoline. Atophanyl is a combination of the sodium salts of atophan and salicylic acid.

The inorganic compounds of arsenic rarely give rise to jaundice nor does sodium cacodylate, which is an organic compound of the fatty or aliphatic series. It is well known that jaundice occurs after the administration of the arsenobenzol compounds of arsenic, and the occurrence of jaundice is no doubt due to the combination of the arsenic with a

benzene nucleus. The quinoline nucleus resembles that of benzene in that its presence may be associated with toxic action on the liver.

The occurrence of toxic jaundice after the administration of preparations which may act as liver poisons is dependent on the condition of the liver cells at the time of treatment. If there is any evidence of defect of hepatic function it is advisable to avoid the administration of any remedies which may have a specific toxic action on the liver cells. It has been recommended to give glucose (50 grams) by mouth a few hours before the intravenous administration of an arsono-benzol derivative to act as a protection of the liver cells by reason of the stored glycogen resulting. I believe this recommendation to be physiologically sound and one that should be practised.

It is probable that the occurrence of toxic jaundice after the administration of atophan, and the other preparations in question, only happens in cases where there is defective hepatic function. The letter of Dr. L. C. Dundas Irvine in the *JOURNAL* of July 17th shows that in many cases the preparations may be safely given, and this is no doubt the experience of many other practitioners. It should, however, be remembered that there is a possibility of toxic action on the liver, and in patients showing evidence of defective hepatic function or of general debility the preparations would be best avoided.—I am, etc.,

London, W.1, Aug. 3rd.

W. H. WILLCOX.

#### THE DEVELOPMENT OF VAGINAL OPERATIONS FOR GENITAL PROLAPSE.

SIR,—In the interesting discussion on this subject in your columns I observe the statement of Dr. R. H. Paramore (March 13th, 1926, p. 502) that, so far as he knows, no one has cured a case of complete prolapse of the uterus by operating on the "visceral connective tissues alone."

If by these "connective tissues" he means the mass of musculo-fibrous tissue passing out laterally from each side of the cervix uteri towards the pelvic wall and filling in the base of the broad ligament, I can assure him that the late Dr. Arthur Nyulasy rectified a number of such cases by shortening those tissues alone. After several years of observation, dissection, and operation, he arrived at the conclusion that these lateral masses or bands of musculo-fibrous tissue "are the main elements holding the uterus at a more or less definite level in the pelvis," and that therefore their most correct title is the "cardinal ligaments of the uterus." They are often referred to as "Mackenrodt's ligaments," but this author's description is quite erroneous. Thus, he describes them as "bands of firm fibrous tissue, which form specialized parts of the pelvic fascia; arising in the neighbourhood of the ischial spines, they pass through the pelvic cellular tissue and are inserted into the sides of the cervix and vaginal vault."

Arthur Nyulasy's original dissections, as described in the *Annals of Surgery* and other journals in 1914, prove that these ligaments are not mere bands of firm fibrous tissue, they are not specialized parts of the pelvic fascia, they do not arise in the neighbourhood of the ischial spines, and they are not inserted into the sides of the cervix and vaginal vault.

On the contrary, they arise from the uterus and pass outwards to be inserted into the pelvic fascia on the lateral wall of the pelvis, and they are packed with bundles of smooth involuntary muscular fibres, whose presence Mackenrodt appears to have quite overlooked.

Five years after the publication of Arthur Nyulasy's papers, his views on the structure and functions of these ligaments were absolutely confirmed by Professors Hastings Tweedy and A. F. Dixon, the well known anatomist, at a meeting of the Royal Academy of Medicine in Ireland in February, 1919, and duly reported in the *BRITISH MEDICAL JOURNAL*. Professor Dixon said the support of the uterus

"was mainly applied at the lateral aspect of the cervix and at the lateral aspect of the vagina. Here the subperitoneal tissue was packed with smooth muscle and connective tissue fibres, radiating outwards along the vessels and nerves which abounded in that region. The dense mass was continuous with the muscle

wall of the cervix and vaginal fornix, and not merely adherent to those structures; in front of these it was continuous with the muscular wall of the lateral angle of the bladder, and formed the ureteral sheath."

It would thus appear that the name of "Mackenrodt" should be dropped altogether in connexion with these ligaments; and, as Mr. Victor Bonney remarked in 1923, "it is time there was a consensus of opinion as to the nomenclature of such important structures." "Cardinal ligaments" seems their most appropriate title.

It may be added that Arthur Nyulasy's operation of "looping the cardinal ligaments in uterine prolapse" is fully described in a volume of his selected papers, which may now be seen in the library of either the British Medical Association or the Royal Society.

The essential points in the operation are these: the cardinal ligaments are exposed as in the operation of subtotal hysterectomy; the uterine arteries are tied, the inner ends of the cardinal ligaments are isolated from the posterior layer of the broad ligament on each side, and stitched (as loops) to the front of the cervix. This has the effect of raising the uterus to such a level as to overcome the prolapse. One of the advantages of operating by this method is that ovarian or other complications may be conveniently dealt with at the same time.—I am, etc.,

FRANK A. NYULASY, M.D.

Melbourne, Australia, May 3rd.

#### TUBERCULIN TREATMENT OF TUBERCULOSIS.

SIR,—I regret that in the cause of truth and suffering humanity I must again briefly refer to the report upon tuberculin treatment at dispensaries issued by the Medical Research Council in 1921. It was originally labelled "Confidential," but I had not asked for a confidential report, and was no party to this condition. Owing to my representations the report was eventually published in the *Lancet* for November 3rd, 1923, without this qualification. I was placed at a disadvantage because the investigators did not wish to meet me in person. I saw them once, and once only, and spent the hour they gave me at the dispensary in showing them the simple, accurate, and easy way we had introduced for measuring the exact doses to be given. Though the method can, I think, hardly be improved, in the report it was ignored, and the method I was compelled to use in Australia, and for some time in England, till I had special pipettes made in Germany for this purpose, was made the subject of criticism. Instead of describing the method in actual use, they used pages of the report to criticize the method, described in my book (1912) which I had discarded for many years—certainly for eight years. There were three investigators (Dr. Western, Dr. Burrell, and Dr. McNalty) and each of them signed this criticism, although each of them had been a witness of my personal demonstration. Let others judge of the value of this kind of criticism. It is hard for me to explain why three independent examiners should fall into so many inaccuracies, and it was surprising that these three medical men subscribed to a statement, without any evidence of all, that "this method of tuberculin administration succeeds in immunizing patients to large doses of tuberculin, but there is no evidence that it also immunizes them to tuberculosis." What evidence is there to support the conclusion, which to some must seem unintelligible? Both the effects and the lesions are the products of the toxins; I presume they meant the effects of the tubercle bacilli. Had they any right to make such a statement? Nowhere have I seen any recorded experiences of any of them with large doses, and they confessed to me that they knew nothing about the use of large doses of tuberculin.

My contention, based upon a very long and careful investigation, is, and always has been, that nothing but large doses of tuberculin can ensure lasting results in chronic forms of tuberculosis, and no authority has a right to criticize my views unless my methods have been tried and found wanting. My critics merely deny or assert but produce no evidence. Certainly my reply to their report should satisfy any lawyer who understands the meaning of evidence, that their way of appraising evidence would not find favour in a court of law. Those who state that there

"no evidence that large doses immunize against existing tuberculosis" are giving a mere opinion, which is contrary to the evidence. I would suggest that on this upmost question affecting millions the Government might appoint a lawyer to determine whether my critics or I deserve the verdict.

It is not necessary for me to criticize again the conclusions reached by this committee, but I will gladly send my pamphlet *The Tuberculin Dispensary for the Poor* to any who wish to read my criticism of this report, and would like to have in return their calm opinion upon the justice of my comments. *C'est la juste mesure, qui vaut le mieux.* I might thus obtain from the medical profession a collective idea of the value of the report, which had received the imprimatur of the Medical Research Council. Further, I invite medical men to visit the Tuberculin Dispensary, 32, Fitzroy Street, Fitzroy Square, W.1, on Mondays and Thursdays, at 9 a.m., and learn by experience what we strive to do and thereby judge for themselves.—I am, etc.,

London, W., July 23rd.

W. CAMAC WILKINSON.

#### SEPTIC SORE THROAT COMPLICATED BY ERYTHEMA NODOSUM.

SIR,—The recent letter on septic sore throat complicated by erythema nodosum (June 19th, p. 1062) leads me to report the following case of ulcerative tonsillitis in a woman aged 20: The tonsillitis was accompanied by much swelling and considerable exudation. After about ten days extensive erythema nodosum developed on both legs, and also just behind the elbow-joints, especially the right, with swelling of the joints. After about another ten days the whole of the erythema disappeared, but was followed by a condition of chronic rheumatism with swelling of the joints, accompanied by tenderness and sometimes redness and intense pain; sometimes one or two joints at a time were affected and sometimes several. This has been accompanied by albuminuria. The temperature was above normal only at the onset of the erythema nodosum, when it was 100° for a day or so; there have been relapses of the joint-pains and swellings. The usual treatment, local and general, for these conditions has been given, and also a restricted diet; and it was only after using a particular drug not generally applied in these cases, but which would do good in cases affected by the meningococcus, that the progress towards a satisfactory recovery was made. The drug used was potassium bromide, given at bedtime every night. She is now taking tonics.—I am, etc.,

D. OWEN WILLIAMS, M.B.

Glandyff, Cardiganshire, June 26th.

#### ANTIGENS FOR THERAPEUTIC IMMUNIZATION.

SIR,—Your leading article on this subject (JOURNAL, July 31st, p. 209), referring to the paper by Sir Thomas Horder and Dr. Ferry, p. 177), describes a method employed by these authors for preparing vaccines as "novel."

With reference to living bacterial vaccines may I point out that in the domain of veterinary medicine the demand for Pasteur's living vaccines (chiefly anthrax and swine erysipelas) goes on steadily increasing year by year, and that the output of the Laboratoire des Vaccins Pasteur (pour l'Etranger), Paris, is now over twenty million doses a year, a proof that the economic value of these living vaccines is recognized by stock owners all the world over as the most valuable yet cheapest form of insurance against epidemics of these two dreaded diseases. Living vaccines for prevention of tuberculous disease both in man and cattle have an increasing band of votaries in more than fourteen countries where State laboratories are now issuing the living Calmette-Guérin bacillus (a non-pathogenic form of the tubercle bacillus of bovine type) for immunization of man and cattle, particularly the newborn, against tuberculosis.

The method described by Horder and Ferry for preparing vaccines, however novel it may appear as applied to human medicine, is well known in veterinary medicine, and in

this connexion I would refer especially to the pamphlet issued by the Toulouse Institute of Serumtherapy on immunization against symptomatic anthrax by amicrobic and integral vaccines (Types B and C). Under Type B, which consists of broth cultures deprived of germs, the following note appears:

"Since 1900 Leclainche and Vallée have shown that candle-filtration lessens the activity of the secretions of *B. chauvoii*. Also no two candle-filters ever behave alike; they retain by adsorption and slime-choking the greatest proportion of the soluble active substances which they are intended to free. . . . In place of filtration, as is utilized by all authors who study antisympomatic anthrax vaccination with microbic secretions, Leclainche and Vallée therefore employ super-centrifugation of cultures. . . . This technique alone yields totally innocuous amicrobic vaccines with a maximum of activity and antigenic value, incomparably superior to those obtained by filtration, however good the latter may be." (The translation is mine.)

There is no reason for supposing that powerful inoffensive antigens may not likewise be found associated with pathogenic organisms in the domain of human medicine, and therefore both Sir Thomas Horder and Dr. Ferry have all encouragement in their interesting, valuable, and patient research.—I am, etc.,

Hendon, N.W.4, Aug. 1st.

MYER COPLANS.

#### ACUTE INTESTINAL OBSTRUCTION.

SIR,—My experience indicates that the tragic rapidity with which acute intestinal obstruction passes the bounds of surgical salvation demands, even at risk of an occasional error, a concise and easily remembered working formula.

(1) In the first instance, after duo local (including rectal and vaginal) revision, in every suspect case, examine heart, lungs, and urine, not omitting a good look at eyes and ears, and a sniff of the breath. Should the diagnosis remain dubious, stand by the case—no "going away and coming back later."

(2) Administer a large soap-water and turpentine enema; if this does not cause an immediate, and distinct, evacuation of faeces or flatus, then and there wash out the stomach, and forthwith transfer the patient to the operating theatre, in which a well heated operating table can be promptly procured. The cold slab is the death-bed of the patient with acute abdominal disease, and every minute before, and during, operation counts.—I am, etc.,

Buenos Aires, May 6th.

JOHN O'CONNOR.

#### HISTORICAL ACCURACY.

SIR,—At the recent Representative Meeting of the British Medical Association, when the question of having a Section of the History of Medicine at the Annual Meeting was under discussion, the statement was advanced as an encouragement for the venture that the last Section, that of Medical Sociology, was also brought forward on the initiative of Brighton, and had been most successful. Had this remark not been quoted in your report it would have been unnecessary to refer to it; but if we are to have history, let us begin by being accurate.

When the question of having a Medico-Sociological Section was first mooted the Brighton Division had not become known. This Division's appearance on the stage—at about the time of the commencement of the temporary eclipse of Wandsworth—was first noticeable when, during an early summer morning walk on the Downs in 1912, the late Medical Secretary and I decided that the local professional pulse should be felt with a view to the Annual Meeting being held in Brighton in 1913.

The question of a Sociological Section was first advocated at a Council meeting in 1908; was referred to a committee which trampled on it as being considered to be foreign to the objects of the Association; was brought up again later; was acquiesced in as an experiment; and held for the first time in London in 1910, Belfast being considered to have a too political atmosphere to start it in 1909! That it has proved each year since an undoubted success goes to show that prophecy in 1908 was for once correct.

By all means let us have a Section of the History of Medicine. Not for the purpose of recounting to an expectant public tales of heroic bloodcurdling forms of treatment culled from records of past civilizations, but to

demonstrate how, in spite of all setbacks, medicine has gradually been freeing itself from legends, myths, traditional lore, and other human imaginings, and has emerged as a science developed in peace and war.

At some distant epoch the influence of this Association; by its varied world-wide activities, will be recognized as having made its contribution to the development of the spiritual, mental, and physical attributes of man, and so be found worthy of being included in such a history. Another prophecy; and yet an encouragement.—I am, etc.,

Hove, July 30th.

E. ROWLAND FOTHERGILL.

## DEFENCE OF ASSISTANTS AND LOCUMTENENTS.

SIR,—I am instructed by the council to bring before the notice of your readers the fact that this union, which enrolls medical and dental practitioners in any part of Great Britain and Northern Ireland, has always accepted responsibility for the acts of their member's assistant or locumtenent. If, therefore, a claim is made, or an action raised against a member of this union in respect of a negligent (or alleged negligent) act of his assistant or locumtenent, the union will defend the case. The union's indemnity insurance scheme, under which members are protected in the event of an action against them being unsuccessfully defended, also covers the member, not only against his own negligence, but that of his assistant or locumtenent.—I am, etc.,

155, St Vincent Street,  
Glasgow, C.2, Aug. 3rd.

W. FINDLAY,  
Secretary and Treasurer, Medical  
and Dental Defence Union of  
Scotland, Limited.

## Universities and Colleges.

### UNIVERSITY OF OXFORD.

DR. WILLIAM BROWN has been re-elected Wilde Reader in Mental Philosophy for five years.

The Master and Fellows of University College, Oxford, upon the report of the Professor of Pharmacology, have awarded the scholarship in pharmacology to Frank Hawking.

On the recommendation of the Waynflete Professor of Physiology, the board of management of the Theodore Williams Scholarship in Physiology has elected F. R. Crookes and J. H. Hunt, whose work was of equal merit, to be Theodore Williams Scholars in Physiology for 1926-27.

### UNIVERSITY OF CAMBRIDGE.

At a congregation held on July 29th the following medical degrees were conferred:

M.D.—J. Rickman, \*F. A. Barker.

M.B., B.Chm.—J. W. H. Stimpson, K. G. Salmon, P. E. Bardsley, R. S. Starkey, J. D. M. Stewart, D. P. Marks.

M.B.—F. W. Roques.

B.Chm.—\*L. G. Higgins, T. E. Fox, G. G. Holmes, F. G. Winterlton, A. W. Spence, \*B. O. Tate, V. B. Wigglesworth, J. H. Hannan.

\* Admitted by proxy.

### UNIVERSITY OF LONDON.

#### LONDON HOSPITAL MEDICAL COLLEGE.

THE entrance scholarship in pathology (value £100), offered by the London Hospital Medical College to students of the Universities of Oxford and Cambridge, has been awarded to Mr. G. E. Lewis, of Christ's College, Cambridge.

#### LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

Dr. R. M. Morris has been awarded a Lalaca medal, in addition to that gained by Dr. R. Crawford and referred to in the list of successful candidates published last week (p. 233); both students obtained an equal percentage of marks.

#### LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.

The following scholarships and bursaries have been awarded for the session 1926-27:—Isabel Thorne Scholarship: Miss H. M. Brown. St. Dunstan's Medical Exhibition: Miss E. J. Adams Clark. Sir Owen Roberts Scholarship: Miss R. E. Chalmers. Mabel Sharmar Crawford Scholarship: Miss P. Farncombe. Alfred Langston Scholarship: Miss P. D. Towell. Flora Murray Bursary: Miss M. M. Fenn. Fanny Butler Scholarship: Miss R. B. Snow. Dr. Edith Pecher-Philpott Post-Graduate Scholarship: Miss G. H. Newell, M.B., B.S.

### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

An ordinary quarterly comitia of the Royal College of Physicians of London was held on July 29th, when the President, Sir John Rose Bradford, was in the chair.

#### Fellowship.

Dr. D. R. Paterson, Dr. G. E. G. Pritchard, and Sir George S. Buchanan were admitted to the Fellowship.

#### Membership.

The following, having passed the required examinations as satisfied the Censors' Board, were elected to the Membership, as all but Dr. Simpson were admitted.

Janet Kerr Aitken, M.D.Lond., Julia Bell, L.R.C.P., Shankar Sah Bhattacharya, M.B.Punjab, Harold Godfrey Bird, M.B.Toronto, Edwin Rowan Boland, L.R.C.P., William Brockbank, L.R.C.P., Norma Francis Clifford Burgess, M.B., L.R.C.P., Vincent Middleton Cost, M.D.Cantab., Daniel Thomas Davies, M.B.Wales, Durga Bati Dhar, M.B.Calcutta, Victor Wilkinson Dix, M.B.Cantab., Hel Winifred Duncan, M.B.Lond., Chester Kingsley Dunstan, M.B.Sydney, Iris Mary Harmer, M.B.Cantab., Kenneth Edwin Harris, L.R.C.P., Richard Athelstone Parker Hill, M.D.Cantab., Alfred Birk Hodgson, M.B.Lond. and Birm., John Holmes, L.R.C.P., Dr. Alexander James, M.B.Aberd., Reginald Sleigh Johnson, M.B.Lond., Edmund Britten Jones, M.B.Adelaid, Alexander Henderson Kirk, M.B.New Zealand, Louis Lavigne, M.B.Durh., Terence Charl. Morton, M.D.Edin., Herbert William Pearson, M.B.Oxt., Eliza Selby Philpott, D.S.O., M.B.Lond., Cyril John Polson, M.B.Birm., Dewan Hakumat Rai, M.C., Major, I.M.S., Thomas Percy R. M.B.Wales, William Austin Robb, M.B.Lond., Hugh Alexander Robertson, M.B.Oxt., John Davy Rolleston, M.D.Oxt., John Whitte Hope Simpson, L.R.C.P., Sidney Smith M.B.Lond., Capt., R.A.M.C. George Henry Wickens, M.B.Melb., F.R.O.S.Eng.

#### Licencees.

Licencees were granted to the following 176 candidates who had passed the recent examination.

R. M. Ainsworth, C. E. H. Anson, J. R. Armstrong, H. Y. Asad, W. Baker, B. Barling, J. T. Barr, A. K. Basilios, \*Florence I. Beel, W. F. D. Benton, P. Berry, W. Blood, \*Hilda M. P. Bond, \*Mabel C. Bower, M. D. Bower, \*Ellen W. M. Bridge, R. C. Brock, R. D. Butler, P. J. L. Capon, \*Rose A. Carter, \*Alison M. Clark, E. H. Claydon, A. P. L. Cogswell, A. H. F. Cole, R. G. Cooke, \*Constance M. Corbett, F. R. Corrie, \*Annie A. Corp, J. B. Crabtree, A. T. Curran, P. J. Curran, E. J. J. Curroji, W. W. Darley, E. A. Darukhanawalla, L. Dass, J. R. A. Davies, \*Mirabel G. Davis, C. A. Day, H. I. Dalt, H. A. H. D'Silva, C. W. L. de Souza, \*Sheila Dewar, G. Dignam, \*Tina Dixon, \*Jean M. Dollar, M. H. C. Dyson, J. P. Evans, R. Evans, S. N. Evans, G. L. Feneley, C. Fernandez, R. F. Fidler, G. W. S. Foster, E. O. Fox, \*Elsa C. A. Fristedt, R. Gallimore, R. C. Germond, F. Goldby, B. W. Goldstone, E. D. Y. Grasby, W. P. Greenwood, J. L. Groom, R. G. Hall, \*Kathleen M. Halloran, T. J. Harcourt, O. H. Harper, S. T. Harris, J. C. Hawkesley, G. G. Hill, W. S. Hinton, A. S. Hollins, M. F. Hope, W. G. S. Hopkirk, \*Nancy G. Howell, J. H. Humphreys, W. T. Hunt, D. H. Isaac, \*Mary R. Isaac, R. James, B. S. Jarvis, B. G. Jennings, \*Mary Jennings, J. D. F. Johnson, A. N. Jones, E. D. Jones, J. P. Jones, B. Kaplan, J. A. Kerr, H. Kesselson, W. R. Kirkpatrick, J. H. Kitson, \*Oliver C. Knight, S. C. H. Lane, W. Leslie, A. L. St. A. McCloskey, A. C. MacGregor, R. M. B. Mackenna, C. W. Mackenzie, E. H. Mackenzie, J. H. Marshall, W. N. Mascall, A. J. M. Melly, \*Bertha I. Meyer, \*Anna P. Montgomery, A. W. J. Morgan, J. Morris, \*Margaret E. Morton, L. Moss, I. Muende, \*Kathleen A. Muir, \*Dorothy L. Neale, E. J. Newman, \*Norah M. A. Niall, H. P. O'Keefe, M. N. O'Leary, L. Owen, J. G. Paley, F. Parker, \*Isabel D. Patterson, R. A. M. Pennington, G. H. Pereira, D. Perkoff, R. K. Phillips, M. M. Pugh, E. I. Puddy, E. J. Pye-Smith, W. F. H. Ray, W. D. B. Read, \*Vivian M. H. Rendall, \*Doris Reynolds, J. E. W. Richardson, F. T. Ridler, \*Bertine M. Rix, \*Phyllis Routledge, E. S. Rudatzky, S. E. Sait, A. E. Y. M. Salama, W. Samarasinghe, W. E. Savage, H. S. Seymour-Isaacs, A. Signalewsky, R. W. A. Simms, E. W. Skipper, \*Peggie P. Slater, S. Smith, J. B. O. Spicer, J. B. Stauffer, K. R. Stokes, \*Stella C. C. Stuart, R. D. Summers, M. M. Suzman, B. O. Tate, E. D. Thomas, L. H. Thomas, \*Mary Thomas, R. Thomas, S. R. Trick, J. M. Turner, \*Dorothy I. Valentine, \*Nora A. Vane-Percy, G. F. Vincent, J. E. Wallace, S. D. H. D. Wallis, \*Kathleen M. Ward, R. F. Ward, T. H. Webb, A. G. Weller, D. P. Whitaker, E. G. Williams, H. P. Williams, \*Jane C. Williams, \*Elizabeth E. Wintringham, H. L. C. Wood, R. E. Tule.

\* Under the Medical Act, 1876.

#### Diplomas.

The diplomas indicated were granted jointly with the Royal College of Surgeons to the following successful candidates:

PUBLIC HEALTH.—E. G. Anthonisz, C. M. Brown, Lily O. Butler, G. E. Cullen, P. P. Daruvala, E. F. Duck, E. James, J. V. Landau, Janet McL. MacKay, Catherine J. MacLaren, R. O. Mahajan, J. A. Struthers, T. Tennant, W. D. R. Thompson, Cicely Weatherall, M. J. Whelton.  
LARYNGOLOGY AND OTOLARYNGOLOGY.—T. A. Clarke, A. L. Clowes, A. O. Day, J. D. Dhruv, P. Garson, W. J. Macdonald, G. S. O. Francis, M. T. Goss, T. Rao, B. D. Ueberall, R. Wheeler.  
SURGERY.—R. A. de G. Basto, S. N. Chan, G. S. Duncan, K. Eweida, S. Fraser, D. Harcourt, R. Lang, E. H. Lim, A. M. MacGillivray, M. McKie, M. E. Mahmood, M. C. Mason, H. P. S. Owen, T. G. W. Parry, W. L. Pencock, T. Pearson, H. Rah, P. R. S. Rao, G. P. N. Richardson, F. W. Robertson, Nina L. D. Robertson, W. J. Roche, K. G. W. Saunders, H. Singh, S. G. Sorabji, T. G. T. H. H. K. Tucker, M. L. Watts, L. E. J. Werner.  
PSYCHOLOGICAL MEDICINE.—G. W. J. MacKay, J. R. A. Madgwick, J. T. H. Madill, A. R. Martin, L. Minski, A. O. Sinclair.

The Murchison Memorial Scholarship was awarded to C. E. Newman, M.B.Cantab, M.R.C.S., L.R.C.P.; and *proxime actus* P. B. Wilkinson, M.B.Lond., M.R.C.S., L.R.C.P., both of King's College Hospital.

Members of committees and examiners for the ensuing year were elected, including:—Censors: Herbert Morley Fletcher, M.D., Robert Hutchison, M.D., John Walter Carr, C.B.E., M.D., Frederick Poynton, M.D. Emeritus Treasurer: Sir Dyce Duckworth.

Bt., M.D. *Treasurer*: Sidney Philip Phillips, M.D. *Registrar*: Raymond Crawford, M.D. *Harveian Librarian*: T. H. Arnold Chaplin, M.D. *Assistant Registrar*: Robert Oswald Moon, M.D.

#### *Harveian Orator and Bisset Hawkins Medal.*

The President announced that he had appointed Sir William Hale-White to deliver the Harveian Oration in 1927, and had awarded the Bisset Hawkins Medal, 1926, to Dr. A. T. Stanton.

#### *Harvey Tercentenary.*

The President reported the following recommendation of the Council, which was adopted:

That it be remitted to a committee consisting of the President, Senior Censor, Treasurer, Registrar, and Harveian Librarian, with power to add to their number, to consider and report to the College on the arrangements that should be made by the Royal College of Physicians duly to celebrate in 1928 the tercentenary of the first publication of Harvey's *De Motu Cordis*.

#### *Various Communications.*

At the request of the Secretary of the Medical Research Council, Lord Dawson and Dr. John Fawcett were nominated to confer with that council on the question of continuing the issue of *Medical Science: Abstracts and Reviews*. A specimen copy of the Osler Memorial medal was accepted, with thanks to the Regius Professor of Medicine at Oxford, Secretary of the Osler Memorial Committee, for the gift. The President reported communications with the Home Office concerning the barbitone group of drugs, including copies of the draft amending regulations under Section VII of the Dangerous Drugs Act, 1920.

Various reports from standing committees were received, and the report of the Departmental Committee on the University of London was discussed. The President then dissolved the comitia.

#### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary council meeting was held on July 29th, when the President, Sir Berkeley Moynihan, Bt., was in the chair.

#### *Diplomas and Licences.*

Diplomas of membership were granted to 174 candidates. Licences in dental surgery were granted to 2 candidates. Diplomas were granted jointly with the Royal College of Physicians: In public health to 16 candidates; in ophthalmic medicine and surgery to 32 candidates.

#### *Appointments.*

A letter was read from Mr. Herbert S. Pendlebury resigning his membership of the Court of Examiners, and suggesting that such resignation take effect on the conclusion of the final examination for the Fellowship in November. The resignation was accepted and the vacancy on the Court of Examiners thus occasioned will be filled at the ordinary meeting of the council on December 8th.

Sir Anthony Bowlby and Sir D'Arcy Power were re-elected, and Mr. Sampson Handley was elected, members of the executive committee of the Imperial Cancer Research Fund.

#### *Lister Memorial Lecture.*

The Lister Memorial Lecture by Professor von Eiselsberg, will be delivered at the College at 5 p.m. on Thursday, July 7th, 1927, and a reception will be held in the museum from 4 to 5 p.m. before the lecture.

#### *The Supplemental Charter.*

The Supplemental Charter, as prayed for by the College, was approved by the King in Council on July 26th.

#### SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have passed in the subjects indicated:

**SURGERY.**—A. C. F. Barrow, A. Henkamp, R. F. Middleton.  
**MEDICINE.**—N. H. Allen, F. W. Barton, T. M. Beattie, W. O. H. Evans, J. B. Lurie, R. I. Richards, G. E. Rowan.  
**FORENSIC MEDICINE.**—O. S. Forrest, H. S. Littlepage, J. B. Lurie, R. F. Middleton, T. E. Moody Jones, A. K. Rama Chandra, G. E. Rowan, R. S. S. Smith, M. Stinnesbeck.  
**MIDWIFERY.**—A. C. Banerji, H. J. J. Fordham, D. Jacobson, V. K. Samy, M. T. Y. Selim, R. S. S. Smith, T. de L. Walker.

The diploma of the Society has been granted to Messrs. W. O. H. Evans, R. F. Middleton, and G. E. Rowan.

## The Services.

#### NAVAL DECORATION.

The Royal Naval Volunteer Reserve Officers' Decoration has been conferred upon Surgeon Commander R. Wilbond.

#### DEATHS IN THE SERVICES.

Colonel B. M. Blennerhasset, C.M.G., Army Medical Service (ret.), died at Rotorua, New Zealand, on May 26th, aged 76. His surname was originally Tincler, and under that name he entered the army, but changed it by deed poll to Blennerhasset in 1879. He was educated in Dublin, taking the L.K.Q.C.P. in 1870, and the L.R.C.S.I. in 1871, and subsequently the F.R.C.S.I. in 1889.

Entering the army as assistant surgeon in 1872 he became colonel in 1902, and retired in 1906. He served in the Ashanti campaign of 1895-96, when he was mentioned in dispatches, and received the star, given instead of a medal for that campaign, and the C.M.G.

Lieut.-Colonel L. J. Pisani, Bengal Medical Service (ret.), died in London on June 22nd, aged 64. He was born at Gibraltar, the son of John Pisani, landholder, and educated at Charing Cross Hospital, taking the M.R.C.S. and L.S.A. in 1886. He entered the I.M.S. as surgeon in 1886, passing first into Netley, but dropping two places during the course there. In 1895 he took the F.R.C.S. He became lieutenant-colonel after twenty years' service, and retired in 1911. After the usual two years' military duty, he took civil employ in the Punjab, but was soon after transferred to the United Provinces. He served on the north-west frontier in the Hazara campaign of 1888, was present at the action at Kotkai, and received the frontier medal with a clasp. He was the author of a work on *The Pathology of Relapsing Fever*, 1889.

Lieut.-Colonel Henry Arthur Bransbury, D.S.O., R.A.M.C., was murdered at Lucknow on July 5th by an Indian servant. He was born on October 2nd, 1877, the son of the late Mr. Henry Bransbury of Southsea, was educated at St. George's, and took the diplomas M.R.C.S. and L.R.C.P.Lond. in 1900. After filling the posts of house-physician and assistant to the medical registrar at St. George's, he entered the army as lieutenant on January 29th, 1901, and became lieutenant-colonel in 1918. He served in the South African war in 1901-2, taking part in operations in the Transvaal and Orange River Colony, and receiving the Queen's medal with three clasps; he served also in the war of 1914-18, when he was mentioned in dispatches in the *London Gazette* of April 5th, 1916, and received the D.S.O.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

PARLIAMENT rose on August 4th for the long recess. The House of Commons is to resume its ordinary business on November 9th, but there will probably be a special sitting on August 30th for renewal of the Emergency Regulations. The Government will take the whole time of the House during the autumn session. The London University Bill, being a Government measure, may be carried, but there is considerable opposition to it. No attempt will be made to advance the Factories Bill which has just been introduced.

Though no decision has been officially announced, the Minister of Health is expected to introduce next year a bill founded on the recommendations of the Nursing Homes Committee. The bill, when introduced, will also propose consequential modifications in the Midwives and Maternity Homes Bill which has just been passed.

The House of Commons passed the Lead Paint (Protection against Poisoning) Bill through report and third reading on August 3rd.

#### Public Health in Scotland.

During the debate in the House of Commons on the Scottish Estimates the question of the duties of education authorities as to the feeding of school children during the holidays was raised. The Lord Advocate said that the education authority's duty arose when it found that, owing to lack of food or clothing, a child was not in a condition to take full advantage of the educational course. It was the duty of the parish council to provide relief while the child was at home.

Mr. Johnston said that in Dundee 4,000 persons lived in houses which had been officially scheduled as unfit for human habitation, and that 1,000 families lived each in a share of a room. The medical officer of health had urged development in house building. Mr. Barr said that the report of the Hospital Services (Scotland) Committee, over which Lord Mackenzie had presided, showed that the hospital accommodation was inadequate; in the six teaching hospitals in Scotland there were 3,256 beds and a waiting list of 5,854. Considering the inadequacy of the medical equipment, remarkable progress had, Mr. Barr said, been made. He recapitulated some of the statistics published in our columns, and quoted some about Glasgow, which will be found at page 272. The Labour party desired to see the whole health service a public service, and the best medical skill available to all without distinction.

Mr. T. Kennedy said that in cases of abnormal sickness national health insurance committees had the responsibility of inquiry and action. The Royal Commission of 1924 had recommended their practical abolition on the ground that the duties were of a routine character, and had diminished. The House should think seriously before assenting to their abolition.

Mr. Buchanan urged on the Scottish Office the need for more rapid expansion in the treatment of venereal disease. Medical provision in Glasgow and Edinburgh was not sufficient. In Glasgow it was not uncommon to have thirty or forty cases a night, and to give each the necessary medical attention was impossible. He referred also to the training of the blind; there was a long waiting list of persons anxious to get training. Mr. Wheatley said that Scotland required 100,000 working-class houses.

Dr. Drummond Shiels said there was no finer Government document than the report of the Scottish Board of Health, but he hoped the Board would encourage local authorities to install artificial sunlight for the treatment of surgical tuberculosis, rickets, and general debility. He pointed out that in Scotland about 50,000 school children had been certified as insufficiently nourished, and about 1,300 as very much undernourished.

In reply for the Government, Dr. Walter Elliot called attention to a previous declaration by the Secretary for Scotland to the effect that the Board of Health hoped in time to arrange for the provision of an increased number of hospital beds. With regard to the provision for treating venereal disease in Glasgow, Dr. Elliot agreed that the situation of the Broomielaw centre was not entirely satisfactory. Further building was going on, and it was hoped considerably to improve the situation. In future, venereal disease would be dealt with in accordance with the terms of the International Convention which had just been ratified. He added an assurance that the Government was not considering at the present time the abolition of the housing subsidy.

#### Mental Cases (Certification).

In a reply on July 29th to Mr. R. Richardson, Mr. Chamberlain dealt with the case of a woman patient who had been committed during June on a doctor's certificate to Gloucester County Asylum. Mr. Richardson asserted that this case had been instanced in a communication recently made by a bench of magistrates to the Board of Control, which communication alleged a lack of proper scrutiny by the Board of the grounds upon which persons were committed to asylums. Mr. Chamberlain said that the patient had been committed on an order made by a justice of the peace. Copies of the reception documents were received by the Board of Control on June 14th, with an intimation that the patient had been discharged on June 11th, the medical superintendent being of opinion that she was not then of unsound mind. There was no question of any lack of proper scrutiny by the Board, because the patient was discharged three days before the documents reached the Board. In the opinion of the Board the facts observed by the certifying doctor at the time of his examination afforded ample ground for the conclusion that the patient was at the time of unsound mind and in need of care and control. It was erroneous to assume, because symptoms of insanity were not found on admission, that therefore those symptoms were not present at the time of certification and that the patient was improperly certified.

Mr. Richardson asked whether, as the Board itself admitted in its report for 1923 that twenty-two cases committed in the previous year were found to be sane on admission, the Minister would give directions that certification in all these cases should be declared invalid and their names erased from the roll of lunatics. Mr. Chamberlain replied that it was impossible to invalidate the certification of these persons. They were sent to mental hospitals under proper legal authority and on discharge their names were removed from the list of certified patients. Some amendment of the law might be desirable to facilitate the provisional observation and treatment, without full certification, of doubtful or transitory cases of mental disturbance, and this would be considered in connexion with the recommendations of the Royal Commission, whose report had just been issued.

Dr. Fremantle asked whether there was any chance of this legislation being introduced next session. Mr. Chamberlain said he was not in a position to make a statement.

On August 3rd Mr. R. Richardson asked the Minister of Health if his attention had been drawn to the recent decision in the Court of Appeal, in the case of *Harnett v. Fisher*, from which it resulted that if any sane person was wrongfully shut up in an asylum for six years he was debarred from redress; and if he would at an early date initiate legislation to remove this. Sir Kingsley Wood, who replied, said that the Minister of Health, was advised that the deduction Mr. Richardson had drawn from the decision of the court in this case was too wide. As to legislation, all that could be added to what the Minister had already stated to the House was that the recent report of the Royal Commission on Lunacy and Mental Disorders was under consideration.

#### Midwives and Maternity Homes Bill.

In the House of Commons, on August 2nd, the Lords amendments to the Midwives and Maternity Homes Bill were, on the motion of Sir Kingsley Wood, agreed to, without discussion. The chief amendment empowers a local supervising authority to grant exemption from the operation of Part II of this Act in respect of (a) any hospital or other premises for the conduct of which a duly qualified medical practitioner resident therein is responsible; or (b) any hospital or institution not carried on for profit and not used mainly as a maternity home.

#### Rural Housing Bill.

The Minister of Health moved the second reading of the Housing (Rural Workers) Bill in the House of Commons on August 3rd. He explained that it was designed to improve the accommodation for agricultural labourers and other country workers. The bill enabled local authorities to submit for the approval of the Minister schemes for the improvement of houses in the country. The schemes would specify the class of houses to which improvements were to be applicable; the alterations were to be structural assistance, by way of loan or grant, or

both, was only to be given to houses whose value, after they had been altered, did not exceed £400. Slums were excluded from this clause. There was also a time limit, which required that applications for assistance must be put in within five years.

Mr. Greenwood moved the rejection of the bill on behalf of the Labour party. It was, he said, virtually a landlord's relief bill.

Dr. Fremantle, in supporting the bill, said that it would be better to sweep away bad houses and build new ones; but this had been tried for the past seven years, with the result that only a few thousand houses had been built. He suggested to the Minister of Health that more attention should be directed to urging the local authorities to make use of the existing power to enforce the better conditioning of rural houses.

The amendment was defeated by 213 to 71, and the bill read a second time.

"Loud Speakers" in Public Places.—The Home Secretary, answering a question on July 29th, said that where the local authority thought a by-law necessary to prevent annoyance to residents or passengers by the use of "loud speakers" in or adjoining streets or public places, he considered they should be allowed to put the by-law into force. In a further reply, on August 2nd, the Home Secretary said he could not intervene against nuisances caused by loud speakers in gardens or open spaces. It was for the local authority to consider if a substantial nuisance existed which could be dealt with by by-law.

Silicosis in Mines.—Colonel Lane-Fox, on July 29th, informed Mr. Paling that it was not necessary to report cases of silicosis among mine-workers. The number of cases was known to be small, and, so far as coal mines were concerned, almost negligible. In reply to an inquiry on August 3rd as to whether any cases of silicosis had been reported which were alleged to have been caused through operating the stone-dusting regulations applying to coal mines, Colonel Lane-Fox said that the allegation had occasionally been made, but that in every case in which it had been made the disease had proved on investigation not to be silicosis.

Cancer Research.—In a statement, on July 29th, Mr. Chamberlain said that the expenditure from public funds directly assignable to cancer research during the three years ending March 31st, 1926, amounted to, approximately, £20,000, in addition to the use of a stock of radium worth £50,000, the property of the Government. This figure did not include any portion of the salaries of permanent officers of the Ministry of Health engaged in this work, nor take account of the cost, not readily estimated separately, of the work upon cancer undertaken by the scientific staff of the Medical Research Council at the National Institute for Medical Research. The Council's expenditure upon research in the more primary parts of the medical sciences, which was as necessary for the solution of the cancer problem as the direct study of the disease itself, had also materially advanced the knowledge of the subject.

Tuberculosis Dispensaries.—On July 30th Mr. Chamberlain said that tuberculosis dispensaries were provided by the local authorities, and it was for them to take such steps as they thought desirable for informing the public of the facilities available at the dispensaries. When next an occasion arose to circulate the local authorities responsible for the carrying out of tuberculosis schemes, he would consider the question of bringing to their notice the expediency of the periodical issue of information as to the location of the dispensaries and the facilities they offered.

University of London Bill.—The scheme for moving the headquarters of the University of London to Bloomsbury and for concentrating King's College and other colleges in that neighbourhood has been abandoned. Alternative suggestions for providing accommodation for the central offices of the University were under consideration, but no final decision has been reached. The University of London Bill has reached the Commons, but was not proceeded with before the recess.

#### Notes in Brief.

The terms of reference to the Committee appointed to consider pay and other matters affecting recruitment of officers and nurses to the medical branches of the fighting services do not include consideration of the sick-berth ratings of the navy.

The Prime Minister believes that protective measures are keeping abreast of current developments in gas warfare.

The Home Secretary is instructing the police to take active steps to enforce the law with regard to the use of effective silencers on motor-cycles, and is issuing a warning to motorists to see that their machines are effectively silenced.

Mr. Amery is communicating with the High Commissioner for Palestine regarding a proposal that a medical officer should be appointed whose principal duty would be to attend on officers of the Government and their families. In view of the small number of British officers and their families in Palestine it was not possible to appoint an officer whose sole duty would be to deal with such cases.

Bacteriological investigations into a recent epidemic of unknown nature in Poplar have yielded no positive result up to July 29th.

The Mental Deficiency Bill, received from the Lords, was read a first time in the Commons on July 29th.

The Factories (No. 2) Bill, the object of which is to consolidate, with amendments, the enactments relating to factories, was read the first time on August 2nd.

In the House of Lords, on August 2nd, the Adoption of Children Bill was read the third time and passed.

On August 3rd the Venereal Disease Act Amendment Bill was read a second time.

## Obituary.

JOHN C. McVAIL, M.D., LL.D., F.R.F.P.S.G.,  
Late Member of the Scottish Board of Health and Deputy  
Chairman, Scottish National Health Insurance  
Commission.

It is with deep regret that we have to record the death of Dr. John C. McVail, whose influence on the development of public health during the last five-and-thirty years has been very great. When in 1922 he retired from the appointments of deputy chairman of the Scottish National Board of Health, he settled in the outskirts of London (Golders Green) and lived there until towards the end of last year, when he went to winter at Torquay. His health, which had not been good for some years, gradually deteriorated, and he died there on July 29th.

John Christie McVail was born at Kilmarnock on October 22nd, 1849. He and his brother, the late Sir David McVail, were sons of Mr. James McVail, a well known citizen of that town. He received his early education there and entered the University of Glasgow and Anderson College, Glasgow, in 1869 for the purpose of studying medicine; he graduated M.B., C.M., at St. Andrews in 1873, and M.D. in 1875. Immediately after graduation he settled in practice in his native town, where he soon built up a large practice and became physician to the local infirmary. Even in those early years, however, his mind was occupied in considering, with the impartiality which remained characteristic of him, problems outside the usual sphere of medical practice. His friendship for Dr. John Borland, the first surgeon to the Kilmarnock Infirmary, led McVail to draw up statistics comparing the results achieved by Borland with those of Lister and other eminent surgeons of the times, which showed that though Borland did not practise antiseptic surgery but a form of rough-and-ready aseptic surgery devised by himself, his percentage of recoveries was as good, or nearly as good, as that obtained by those who had adopted the antiseptic method.

During his early days in Kilmarnock a volume on vital statistics gave the causes of every death in the burgh of Kilmarnock, and Dr. McVail was struck by the fact that the records of death afforded appalling evidence of the great prevalence of small-pox among children in the early part of the nineteenth century. This suggested to him an investigation into the subject of small-pox and vaccination, the result of which was a book entitled *Vaccination Indicated*, of which the first edition was published in 187. The wide knowledge that he acquired of vaccination from every point of view led to his being one of the principal witnesses called by the Royal Commission on small-pox, and at a later period, when he gave the Milroy lectures before the Royal College of Physicians of London in 1919, he selected as his subject *Half a Century of Small-pox and Vaccination*, afterwards published in a book with that title. These lectures contain a masterly summary of what is known in regard to vaccination. In 1902 he wrote

W. Crook, Edinburgh.

prior to the passing of the Act provided for the appointment of time medical officers, and in February, 1891, McVail was appointed as the first medical officer of health of the counties of Stirling and Dumfries. This large area was then, from the public health point of view, practically a virgin field, and with characteristic energy and enthusiasm he threw himself into his new duties of organizing and improving the sanitary administration of the counties. Schemes for the provision of water supply, sewerage, and later on scavenging, had to be devised with, and carried out, all kinds sought out and abated. At the time of McVail's appointment the only provision that had been made in Dumfriesshire for the isolation of infectious diseases was a wooden shanty situated near Dumfries, which was intended to serve the needs of the town as well as of the surrounding county area. The admirable series of annual reports presented by McVail to the county councils during this period bear ample testimony to the excellent work he performed in their service; the problems he was called upon to solve carried his reputation

for the British Medical Association a pamphlet entitled *Facts about Small-pox and Vaccination*. A second edition was published in 1905, and he revised it again in 1924. The evidence he gave before the Royal Commission on Vaccination, 1889-96, displayed in a remarkable manner his comprehensive knowledge of all matters relating to small-pox and vaccination, and from that time onwards he was generally recognized as one of the ablest exponents of the subject.

In 1885 McVail took the D.P.H. of Cambridge University. It was no easy thing for a busy man with so many other claims on his time and attention to find the leisure to prepare for such an examination, but he adopted the expedient of refraining from reading the daily papers during the preparatory period and of employing the time generally thus spent in serious study. Whenever he had a few moments to spare, some book or pamphlet on public

health was always in his hand. The new health era was then beginning to dawn in Scotland, and McVail was one of the first to grasp its significance and to realize what might be accomplished by improved environmental conditions and the application of preventive measures to bettering the health of the people and diminishing the incidence of disease. His early aspirations in this direction were fostered and encouraged by his warm personal friendship with the late Sir George Buchanan, Sir William Power, and other medical officers of the English Local Government Board. McVail's appointment as medical officer of health for Kilmarnock in 1886 gave him his first real opportunity of practising the principles of preventive medicine. He soon came to be recognized as one of the leading authorities on all matters relating to sanitation and public health, and in 1887 he was elected President of the Sanitary Association of Scotland.

County councils were established by the Local Government (Scotland) Act, 1889, and with the view of securing a more effective sanitary administration than had been maintained in rural areas, the appointment of whole-time medical officers of health of the counties was provided for. This large area was then, from the public health point of view, practically a virgin field, and with characteristic energy and enthusiasm he threw himself into his new duties of organizing and improving the sanitary administration of the counties. Schemes for the provision of water supply, sewerage, and later on scavenging, had to be devised with, and carried out, all kinds sought out and abated. At the time of McVail's appointment the only provision that had been made in Dumfriesshire for the isolation of infectious diseases was a wooden shanty situated near Dumfries, which was intended to serve the needs of the town as well as of the surrounding county area. The admirable series of annual reports presented by McVail to the county councils during this period bear ample testimony to the excellent work he performed in their service; the problems he was called upon to solve carried his reputation

far beyond the immediate sphere of his administration. His special report, dated 1909, to the Scottish Local Government Board on the housing of miners in the counties for which he was medical officer of health was an excellent piece of work.

One of the difficulties associated with the system of county public health administration in Scotland has been the frequent attempts made by burghs to extend their boundaries, which, if successful, entailed loss, and sometimes considerable loss, of rateable areas to the district committee of the county concerned. McVail was engaged as an expert witness in many such controversies, both in the counties for which he acted as medical officer of health and in other parts of Scotland. His intimate knowledge of the whole subject, combined with his grasp of detail of any particular case and the clear and concise manner in which his evidence was invariably given, always carried great weight with the tribunal before which such cases were heard. McVail was a keen epidemiologist, and all outbreaks of infectious diseases in the areas under his control were promptly and thoroughly investigated. His account of an outbreak of small-pox which occurred in 1892-93 among the navvies engaged in the construction of the West Highland Railway illustrated the experiences and problems—difficult but stimulating—which that disease may bring to the health administration of a rural area which was, at that time, unprovided with the preventive equipment of a town.

In 1905 McVail was invited by Cooper Medical College, San Francisco, to deliver the Lane Lectures on preventive medicine. He went to San Francisco in 1906, shortly after the earthquake had devastated the town. This admirable series of lectures was subsequently published in a book, with the title of *The Prevention of Infectious Diseases*.

In 1907 McVail was appointed by the Royal Commission on the Poor Laws and Relief of Distress to report on the methods and results of the present system of administering indoor and outdoor Poor Law medical relief. For this purpose he made a very careful study on the spot of certain unions in England and Wales selected as typical. This report was an excellent piece of work. He described Poor Law medical relief, both urban and rural, as "a cripple supported on two crutches—the general hospitals on one side, and gratuitous medical work on the other." He dwelt on the paramount importance of preventing disease, and suggested that in any scheme of reorganization of the Poor Law medical service the medical functions of the guardians should be transferred to the health authorities, though in this connexion he strongly emphasized his opinion that the rural district councils would be unsuitable bodies for the purpose, and indirectly referred to the need of reformation or reorganization of the sanitary government of rural England.

When the National Health Insurance Act came into operation McVail was appointed, in 1912, deputy chairman of the National Health Insurance Commission for Scotland. It was with sincere regret that he severed his official connexion with the counties of Stirling and Dumbarton, in which he had spent such happy and fruitful years of strenuous activity; but his experience and abilities were required to assist in the inauguration and administration of the new system in Scotland, and he unhesitatingly responded to the call. His work at the Insurance Commission, and afterwards as member of the Scottish Board of Health, is well known.

For many years McVail was an active and influential member of the British Medical Association. In the year 1904 he became chairman of the Glasgow North-Western Division, and in the following year was appointed president of the Glasgow and West of Scotland Branch. For a number of years he acted as a member of Council of the Association. He was secretary of the Section of Public Medicine in 1888, vice-president in 1898, and president in 1903 of the Section of State Medicine, and president of the Section of Medical Sociology in 1912. He was a member of the Constitution Committee which drafted a new constitution for the British Medical Association in 1900-01. The Association had been founded at Worcester in 1832

under the name of the Provincial Medical Association, and by 1856, as it had enlarged very considerably, it changed its name into the British Medical Association. The Association's membership had by this time increased from the original 50 to 2,094, and by 1884 it numbered nearly 12,000 members. In 1899 the organization of the Association, especially as regarded representation of general practitioners in its government, had caused a great deal of discussion. A schism was threatened by the formation of a medical guild at Manchester, in which thirty-five medical societies and six Branches of the British Medical Association were represented. A conference was held, at which it was decided that the objects aimed at could best be attained by reorganization of the British Medical Association. The result was the appointment of a committee to revise the constitution of the Association; McVail was a member of this committee, and took an active part in its work. Later on he wrote a historical sketch of the steps by which the present constitution had been achieved, which was published in the *BRITISH MEDICAL JOURNAL* in June, 1924, and later in a pamphlet. McVail received the Stewart Prize of the British Medical Association at the Annual Meeting in Glasgow in 1922. A testimonial presented along with the prize by Sir William Macewen, then President of the Association, said that it had been awarded to McVail in recognition of the important work he had done during a long life devoted to public health. After recapitulating the steps through which he had passed in public health work, Sir William Macewen declared that his painstaking investigations, his lucid reports, and his wisdom in council displayed during the period of his appointments had placed Dr. McVail in the front rank of public health officers.

Charles Lamb once remarked that his most important works were to be found on the shelves of the India Office, and so Dr. McVail's most important labours are on record in the many reports he issued while a medical officer of health, and afterwards as the deputy-chairman in the Scottish Board of Health. Yet he found time for many published articles, chiefly connected with his own subject of preventive medicine. In addition to the works already referred to may be mentioned his "Report on Medical Relief to the Royal Commission on the Poor Law" (to be found in Vol. 14 issued in 1909), and his article on preventive medicine in Allbutt and Rolleston's *System of Medicine* (1906).

From the time when he first took up public health work and began to write about vaccination he was a frequent contributor to the editorial columns of the *BRITISH MEDICAL JOURNAL*; when he was appointed a member of the Insurance Commission and of the Board of Health in Scotland, he became too immersed in the duties of these offices to continue, but he was still ready to advise on general principles. When he retired and came to live in London he declared that for the rest of his life, which he did not expect to be long, he would do nothing; but, without any very great difficulty, he was inveigled into breaking his resolution on occasions, which, happily, became more and more frequent.

During his long professional life McVail contributed a large number of articles to the medical journals and gave many interesting addresses on different aspects of public health work. His language, whether written or spoken, was always clear, forceful, and to the point, and he did much to educate the public as well as the medical profession in the advantages to be derived from the practice of preventive medicine. To some of his writings reference has already been made; it would be wearisome to attempt to enumerate them all, for he was always ready to step into the breach when he thought his experience would be of service to the public or to the profession; we may, however, recall—for the fact that he gave it is not generally known—the address on small-pox and vaccination which, at the request of the Ministry of Health, he delivered in 1923 to members of Parliament in one of the committee rooms of the House of Commons. He divided his subject matter under four headings—namely, (1) small-pox is worth preventing; (2) small-pox can be prevented by vaccination; (3) small-pox cannot be prevented without vaccination; (4) properly conducted vaccination is very safe. It was a clear and concise

exposition of the subject, and it is difficult to believe that anyone who considered it dispassionately could fail to be convinced of the value of vaccination.

Among the many distinctions bestowed upon McVail may be mentioned the LL.D. degree conferred upon him by Glasgow University in 1908; his appointment in 1912 to be Crown member for Scotland on the General Medical Council, a position in which he succeeded his brother, Sir D. C. McVail, a distinguished Glasgow physician. He was a Fellow of the Society of Edinburgh, and had been President of the Royal Society of Sanitary Association of Great Britain and of the Incorporated Sanitary Association of Scotland. In 1906 he was presented with the Jenner Medal of the Royal Society of Medicine, and at the time of his death he was president of its Epidemiological Section. It has been a matter of some general surprise and regret that McVail did not receive any recognition from the dispensers of titular honours of his services to the public.

Like most men of outstanding ability, McVail was of a modest and retiring disposition. His genial manner and kindly disposition endeared him to all, while his anecdotes, failing source of delight to his friends. He was an earnest seeker after truth in the many problems which he was called upon to investigate during his busy life. In all that he did it was only the best that satisfied him, and no sooner was one piece of work accomplished than with undiminished energy and enthusiasm he commenced another. He had always great sympathy with the younger members of the profession who wished to adopt the preventive side of medicine as a career, and many men now holding important positions in the public health service owe him a debt of gratitude they can never repay. To the very end he retained the keenest interest in preventive medicine and all that pertained to it, and the calm philosophy with which he faced his last and the calm fitting termination to a life ungrudgingly spent in the service of his country. He was one of Scotland's great men.

*Personal Tributes.*

Sir GEORGE NEWMAN, K.C.B., M.D., Chief Medical Officer of the Ministry of Health and Board of Education, has been good enough to send us the following appreciation:

Scotland has lost a very good man indeed by the death of Dr. John McVail, and it is a loss which will be quite as much felt in England. For McVail belonged to us all. Yet no one who knew his long struggle against disease can be other than thankful that it is over. "We must all go out," he said the other day to a friend, "but this is a poor patience and endurance and splendid courage, McVail made it a great and rich way. He was, in fact, a very brave man, and has left a worthy heritage behind, an inheritance for others of work well done and of a spirit which knows not defeat."

I always looked upon McVail as a typical Scotsman. He was strong physically, hard-headed in the sense of wanting facts and abiding by them, thorough-going and downright, with immense stores of energy and persistence. He had also the inquiring mind, which looked forward even though it built on the past. I must speak with due respect for he was in practice when I was a child—but I think his disposition to inquire and question and probe must have been innate, and probably made him a good student in his Glasgow days. When I joined the Epidemiological Society in 1896 McVail had been a member for seven years, and my first recollection of him was in connexion with that society. He was then county medical officer for Stirling-shire and Dumbartonshire, having previously been in practice for eight years in his beloved Kilmarnock. It was in the cemetery there he learned much of his history, and there he now rests.

Somewhere about 1906-07 McVail became an investigator under the Poor Law Commission, and explored the social relations of medicine. He was exceptionally good at this, and brought to it all his experience and his knowledge of domestic life and habit acquired in Kilmarnock.

Undoubtedly it was partly this work which led to his appointment some five years later as an Insurance Commissioner for Scotland and as Crown nominee on the General Medical Council. It was the last lap, but it lasted ten years. They were very happy, busy years during which he was at maturity and rendering invaluable service to the nation. It seems a good order of events, first general practice, then a county medical officer, then a civil servant in a wide and ever-extending sphere.

One of the services for which McVail is best known is his work on vaccination. Vaccination indicated a wide circulation, and its author inevitably appeared in defence on many occasions. The small-pox records at Kilmarnock were called in witness, and he became a formidable controversialist. He was ever a fighter and smelt the fray from afar. The last address I heard from him on the subject was in a committee room of the House of Commons—to a large company of members. I always thought he excelled in positive presentation rather than in debate, when he was liable to be enticed by the enemy, or the mischievous, into long-winded argumentations which appeared to have no goal. He was, however, a good talker, and his persuasiveness and logic, and the intonation and pronunciation of his words were, to me, attractive and characteristic. I am afraid I have sometimes found myself, inadvertently, among the mischievous, but it was all very enjoyable, and to be fixed and pummelled by him most of himself. He was full of humour, a very human, homely, and affectionate person, a true and faithful friend, a hater of humbug, wise in counsel, devoted to duty, and very courageous. He would have signed the Solemn League and Covenant, and gone to the stake, for his conscience was his king. Yet he was a great civil servant, and his life was a unity.

We are indebted to Sir NORMAN WALKER, his colleague in much of the later work he did in Scotland, for the following tribute:

I had known Dr. McVail for many years, but it was after 1911 that I was brought into close contact with him and learned to appreciate his sterling worth. We worked together on the Highlands and Islands Medical Service Board, on the Emergency and the Committee, on the General Medical Council, and the Scottish Board of Health. He was a very true friend to the medical profession, and gave a great deal of thought to what were its real interests. He somehow inspired confidence, and the comparatively smooth working of the Insurance Act in Scotland was largely due to the confidence which Islands doctors felt in McVail. On the Highlands and Islands Board he spared no pains to ensure that the best possible service should be given to the people under the best attainable conditions for the doctors, and held a very wise balance between the extreme bureaucratic and the extreme professional side. The improvement in the medical service in the Highlands and Islands was a great gratification to him. During the war he took a very large share in the working of the Emergency Committee, and it seems to me only right, now that he has gone, to give him the deserved credit of being one of the instigators of the prominent part the organized medical profession took of service, and argued that, if the medical profession did not do these things themselves, they would be imposed on them from above, and some of us know how very near the truth he came in that! In the proceedings of the General Medical Council, on which he was Crown nominee for Scotland during ten years, he very wisely at first gave time to acquaint himself with the procedure of that body. His direct interest in public health, and his conviction that the general practitioner should take a larger and larger share in preventive medicine, persuaded him that it was not regulations, but education of the medical students, which was the real solution. There were many members concerned in the proposals which resulted in the recent reform of the curriculum, but the man who started them was John McVail.

To Dr. G. MATHESON CULLEN, medical officer of the Scottish Board of Health, we owe the following notes, which show deep understanding of McVail's character and aims:

To those who had the privilege of friendship with John Christie McVail the news of his passing will bring a pang of deep regret. His years had stretched beyond the Psalmist's span; and they had been fulfilled of good work done in various fields, so that there is no grief at unaccomplished purpose. Rather is it the inevitable sadness associated with the vacant chair, the hearty handshake that will grip no more, the merry eye for ever closed. For his was a personality that made pleasing and permanent impressions.

My own knowledge of McVail only began when he entered on the last phase of his official career. He had then reached an age when most men sigh for the easy life, the rest after toil; but to him the attraction of his new duties appeared to lie in the fresh opportunities for work which they offered. And he worked indeed. There can be little doubt that the success which crowned the administrative board of which he was a member was largely due to him; to his abounding energy, tireless work, unflinching tact, breezy good humour, crassaque Minerva. There was nothing of the sexagenarian about him but the years. His vitality was immense, his good humour infectious, his fund of stories inexhaustible.

To every problem McVail brought a fresh and keen interest, with a calm and critical evaluation of all the facts. It was so even when the problem was that of his own life—or death. A dread disease laid an icy hand upon him, but his cheery smile gave no suggestion of the least anxiety; his pain elicited no murmur of complaint. Within an hour of leaving him at a meeting, where he was discussing matters with his usual animation, he telephoned me to say that he would be absent from the office for some time. Thinking that he was holiday bound, I expressed the hope that he would enjoy the rest and change. Then for the first time I learned that he was entering a nursing home that evening for a serious operation. "As I may never come out," he explained, "I did not care to leave without, at least, bidding you good-bye."

The six years that have elapsed since then have been faced with the same spirit. He survived the operation with a struggle; his fine physique triumphed. And when he took up his duties again it was with "scarce abatement of his cheerfulness, or pretermission of the daily craft." No word of his betrayed the fact that his doom was sealed, that in all probability a short month or two would see the end. Only a very few trusted friends knew of the disabling, cruel chain, that fettered his body from that time onwards. And his optimism had its reward. The progress of the fell disease was unaccountably stayed. He finished his term of office, and then retired to London. Even then he did not retire from work, for the time of his residence in the metropolis was filled with interesting and useful occupation.

Such strength of purpose is not seldom associated with a certain sternness of character that does not breed friendship, but it was not so with McVail. It is true that his early training as a school teacher made him somewhat dogmatic in manner; he had no words of glozing courtesy for incompetence; his was not the nature to suffer fools gladly. But no one knew better how to rob directness of its sting; no one could be more spontaneous and generous in his praise of good work. Altogether the elements were so mixed in him that the result was a man whom his opponents could esteem and admire; the type of man that makes many friends and binds them to him with enduring ties. To them, the pain of this rough tearing of the bonds the soothing hand of Time will dull; the ragged wound will heal; but the resulting scar will bear mute testimony of the wrench till for them, too, the inevitable hour shall come.

The death occurred, at the age of 74, at his residence in Musselburgh, near Edinburgh, on July 18th, of Dr. A. D. R. THOMSON. He was the son of the late Dr. L. R. Thomson of Dalkeith. He was educated at a private

school in Musselburgh and afterwards studied medicine in Edinburgh; he obtained the licences of the two Royal Colleges in 1876. In 1882 he became a Member of the Royal College of Physicians and was elected a Fellow in 1890. At the time of his death he had been for over forty years medical officer of Loretto School at Musselburgh; he was also medical officer of Inveresk Parish and certifying surgeon for the district under the Factories and Workshops Act. He became a member of Musselburgh Town Council with the avowed purpose of securing the erection of a modern fever hospital in the burgh; he had to continue his efforts for several years, but was ultimately successful in persuading the Town Council to go forward with the project; he retired from public service when the scheme was completed. Dr. Thomson was a keen golfer and a cricketer also; he was captain Dalkeith Cricket Club and played also for the West Scotland Club. Latterly his chief recreation was shooting but he continued to ride to hounds till advanced in years. He was an angler also, and was noted as a billiard player. In the old days, before the advent of the motor car, Dr. Thomson was an impressive figure as he went his dai rounds in a high dogcart with a high-stepping horse. His wife, who predeceased him by some years, was also of a medical family, having been a daughter of the late Dr. A. M. Sanderson of Edinburgh. The loss of Dr. Thomson, who is survived by a son and daughter, will be mourned over a wide area and by patients of all degrees in the Lothians; his memory will be cherished by many as that of a good doctor, a valued citizen, and a constant and cherished friend.

Dr. DANIEL MACPHERSON TAYLOR, who died at his residence at the Halifax Sanatorium on July 10th, was born in 1868, and received his medical education in Glasgow where he graduated M.B., C.M., with high commendation in 1891, and proceeded M.D. in 1904; he obtained the D.P.H. in 1906. After a period of general practice in London and York he was appointed school medical officer to Halifax in 1910, and interested himself particularly in the work of the Bermerside Open-Air School and Home. In 1913 he became tuberculosis officer, assistant medical officer of health to the county borough of Halifax, and resident medical superintendent of the corporation's sanatorium at Shelf, appointments which he retained up to the time of his death. During the war he held a commission in the R.A.M.C., and served in Mesopotamia; there is no doubt that his health was seriously impaired by this and by the loss of a son in the war. He devoted himself particularly to tuberculous ex-service men, and won a wide popularity as a diagnostician and an agreeable colleague. He leaves a widow, two daughters in the nursing profession, and a son who is still at school.

Dr. REGINALD ERNEST HORSLEY, who died on July 22nd at the age of 62, was a native of Sydney, New South Wales, and was educated at Sydney Grammar School, Trinity College, Melbourne, and the Universities of Edinburgh, Dublin, and Berlin. He graduated M.B., C.M., Ed. in 1885, obtained the diploma F.R.C.S., Ed., in 1890, and proceeded M.D. in 1893. After serving as secretary to the scientific staff of the Challenger Expedition Commission he held the posts of assistant in the ear and throat wards of Edinburgh Royal Infirmary, surgeon to the Edinburgh Ear and Throat Dispensary, aurist to the Edinburgh Institution for the Education of Deaf and Dumb, and physician and lecturer on biology at Stonyhurst College. He was secretary of the section of otology at the International Medical Congress in Berlin in 1890. Dr. Horsley was also a justice of the peace and Provost of the Royal Burgh of Crail, Fife, a position which carried with it the ancient title of "Admiral of the Forth." He retired from the active practice of medicine more than twenty years ago, and had since been engaged in literary work; his publications included *The Romance of New Zealand* (in the Romance of Empire Series), *In the Grip of the Hawk*, *The Blue Balloon*, *The Red Hussar*, and other novels.

Members of the Association who have had occasion frequently to visit the Central Offices will learn with regret that the senior porter, Mr. SAMUEL COX, died suddenly on July 28th, from pulmonary haemorrhage, at the age of 54. His early life was spent in the 11th Hussars, with which he went through the Chitral campaign. During the South African war he was General French's personal dispatch rider. He entered the service of the British Medical Association in 1902, and was called up at the beginning of the great war, throughout which he served in the Army Service Corps as saddlery sergeant. While with the British Medical Association he discharged numerous functions, always with courtesy and diligence. Almost his last duty, performed during the recent Annual Meeting, was to carry the Nottingham flag before the President in the procession to St. Mary's Church. Mr. W. G. Spencer, the Honorary Librarian, desires us to add his appreciation of Cox's services as library porter, and particularly during the change from the Strand to Tavistock Square. "He was," Mr. Spencer says, "one of the most obliging and all-round efficient men I have ever met."

## Medical News.

At the Post-Graduate Hostel, Imperial Hotel, Russell Square, London, a discussion on the silhouette radiogram in the interpretation of clinical signs will be opened on Thursday, August 12th, at 9 p.m., by Mr. A. P. Bertwistle, F.R.C.S. Ed. Ladies and friends of medical men are invited to attend. Two discussions were held last week. Dr. Finsterer of Vienna, on his way from Nottingham, where he had taken part in the discussion in the Section of Surgery on gastro-enterostomy, spoke on operations on the stomach; Sir William Wheeler, who was in the chair, emphasized the diagnostic importance of a course of arsenic in deciding whether the case was one of anaemia or carcinoma. The second discussion was opened by Sir George Lenthal Cheate, who dealt with the difference between hyperplasia and inflammation, which he regarded as two distinct entities. He illustrated his remarks by lantern slides.

The late Sir Henry Morris, Bt., F.R.C.S., has left estate of the value of £44,768, with net personality £44,602. He directed his executors to offer the portraits of himself by W. W. Ouless, R.A., to the National Portrait Gallery, and, if not selected by them, to the Royal College of Surgeons and the Royal Society of Medicine.

In aid of King Edward's Hospital Fund for London visits to the Tower of London are being arranged for August 11th, 18th, 25th, and September 1st. Mr. Walter Bell, F.S.A., will give addresses and conduct parties round the building, and an opportunity will be afforded to visit Queen Elizabeth's Walk and the Bell Tower. Parties will assemble at the entrance gates at 2.30 p.m. (nearest Underground station, Mark Lane). Early application for tickets (price 7s. 6d.) should be made to the Secretary of the Fund, 7, Walbrook, E.C.4.

The Fellowship of Medicine announces that the special course in diseases of children at the Queen's Hospital from August 16th to 28th will include demonstrations, lectures, and operations in the various departments of the hospital. From August 23rd to Sept. 4th the Queen Mary's Hospital, Stratford, will provide an all-day course of instruction in all departments. Regular weekly courses in obstetrics are now offered at the City of London Maternity Hospital; practical courses in anaesthetics can be arranged on application to the Fellowship. The September special courses include: diseases of infants, electrotherapy, ophthalmology, orthopaedics, psychological medicine, and an intensive course in medicine, surgery, and the specialties. Copies of all syllabuses, the general course programme, and the Fellowship journal may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

A POST-GRADUATE course in non-pulmonary tuberculosis will be held at Heatherwood Hospital, Ascot, Berks, from September 23rd to 25th inclusive. The programme includes discussions on light treatment, diseases of the spine and hip, and the after-care of surgical tuberculosis. It is stated that the course has been approved by the Minister of Health as ranking for a grant. The fee is one and a half guineas, and further information may be obtained from the honorary secretary, Joint Tuberculosis Council, Post-Graduate Courses, 19, Brunswick Square, Camberwell, S.E.5.

The eighth Karlsbad International post-graduate course in balneology and balneotherapy will be held from September 12th to 18th. Professor George Barger of Edinburgh will

deliver a lecture on the chemistry of hormones. The course is open to all medical practitioners, for whom full opportunities for studying the local therapeutic institutions will be provided. In connexion with the course a Czecho-Slovakian visa will be supplied without charge and a 33 per cent. reduction allowed on the State railways. Further information may be obtained from the secretary, Dr. Edgar Ganz, Karlsbad.

A POST-GRADUATE course in dermatology and venereology will be held at the Strasbourg Faculty of Medicine from September 20th to November 6th, under the direction of Professor Pantrier, assisted by Professors Barré, Blum, Canuzy, Merkle, and others. A course on the principal laboratory methods and the general morbid anatomy of skin diseases will be held at the same time; the fee for each course is 300 francs. Further information can be obtained from Professor Pantrier, 2, Quai Saint-Nicolas, Strasbourg.

THE twenty-sixth French Congress of Urology will be held at the Paris Faculty of Medicine on October 5th under the presidency of Dr. Marion, when a discussion on the vesicoureteral reflux will be introduced by Dr. Lepoutre of Lille. Further information can be obtained from Dr. O. Pasteanu, 13, Avenue de Villars, Paris VIIe.

UNDER the direction of Professor Jeanselme three autumn courses will be held at the Hôpital St-Louis, Paris, the fee for each being 250 francs. During October there will be a dermatological course, and in November one in venereal diseases, while from November 29th to December 22nd the two subjects will be treated from the therapeutical standpoint. Further information may be obtained from Dr. Burnier, Hôpital St-Louis, Paris.

THE twenty-second international medical post-graduate course will be held at Vienna from September 27th to October 9th, the subject being modern therapeutics; in connexion with it there will be a course in public health. Further information may be obtained from Dr. A. Kronfeld, Porzellangasse 22, Vienna IX.

WITH the co-operation of the Union of American Biological Societies a monthly periodical, *Biological Abstracts*, will appear shortly and include epitomes of the literature of the world dealing with theoretical and applied biology, excluding clinical medicine. Individual biologists can obtain the journal for an annual subscription of nine dollars. Further information may be obtained from the editor, *Biological Abstracts*, University of Pennsylvania, Philadelphia, Pa., U.S.A.

A BOOK entitled *Les Héros sans Gloire* has been prepared by Madame A. Roné-Prouillhot, the widow of a French army medical officer who died during the war. She has collected material industriously, and the volume is dedicated to the memory of the surgeons who died for France. It will be published shortly (price 25 francs) by C. Laroche et Cie, 124, Boulevard St-Germain, Paris, to whom subscriptions may be sent.

A NEW publication entitled *Archives médico-chirurgicales de l'appareil respiratoire* has been established in Paris (G. Doin et Cie); it deals with physiological, medical, and chemical researches into the pathology of respiration. The editors are Drs. Pierre Pruvost and Jean Quénu.

A WELL illustrated pamphlet entitled *At the Meeting of the Ways* has been issued in support of an appeal by University College Hospital for money to provide an additional annual income of £15,000. As reported at the time, the Prince of Wales opened the new hospital extensions—namely, the obstetric hospital and the nurses' home—at the end of May, and unveiled a memorial tablet at the new Royal Ear Hospital, which has been rebuilt as part of University College Hospital. The hospital was founded ninety-three years ago, and was, we believe, the first hospital established in this country as part of a medical school and with a direct connexion with a university. The pamphlet describes the nature of the work in the various departments; copies of it may be obtained from the secretary of the appeal committee at the hospital.

THE sterilization of milk and butter by the electric current, ozone, and ultra-violet rays forms the subject of an interesting article in the *Revue générale des Sciences pures et appliquées* for May 15th, by the agricultural engineer, M. Antoine Rolet.

IN the recent massage examinations four blind students from the National Institute's massage school were successful, one of them being the holder of a Gardner scholarship. This examination is held in open competition with sighted candidates.

THE London County Council has added the name of Professor Alfred Pinner, M.B., director of pathology at Charing Cross Hospital, to the panel of expert pathologists who may be called in by coroners in connexion with inquests of exceptional difficulty.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. **Correspondents** who wish notice to be taken of their communications should sign their names, not pseudonyms.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:  
**EDITOR of the BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.**

**FINANCIAL SECRETARY AND BUSINESS MANAGER**  
(Advertisements, etc.), **Articulate Westcent, London.**

**MEDICAL SECRETARY, Mediscera Westcent, London.**

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: **Bacillus, Dublin**; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: **Associate, Edinburgh**; telephone: 4361 Central).

### QUERIES AND ANSWERS.

#### PAIN AFTER ARTIFICIAL MENOPAUSE.

"**GLENSTRAL**" writes: In reply to "D. K. M. D." (July 31st, p. 235), from the data which he gives, I should imagine his patient has suffered from visceroptosis, and consequently some degree of pelvic floor prolapse, since puberty. I would suggest posterior colporrhaphy and ventral fixation of the uterus, as well as the wearing of a Curtis support.

#### INCOME TAX.

##### Production of Accounts.

"**J. O. R.**" complied with the request of the local inspector of taxes to send him copies of the accounts of his practice for the past three years; he has since received a request to state the names and addresses of the locumtenents whose remuneration is included in the expenses.

Probably the official in question desires the information, not with a view to verifying our correspondent's accounts, but to see that the locumtenents have accounted for any liability there may be on their part. The request is one which can be enforced as regards any locumtenents who may have had other employment in the same financial year. No doubt they have accounted for their own liability, and the request may, we think, be met.

### LETTERS, NOTES, ETC.

#### OPEN AIR FOR COWS.

FORESEEING the difficulties that were coming for arable farming a Berkshire farmer, Mr. A. J. Hosier, resolved to take to grazing and purchased a farm of 1,000 acres on the Wiltshire Downs, where he put into practice certain new principles he had thought out. He determined to specialize in milk production on an all-grass holding, to keep his cows out night and day (winter and summer), to give up mixed husbandry, and to that end to bring such tillage land as there was on the farm under grass. His only crop is hay, and the only additional food he purchases is cake. Every calf is sold. He buys heifers, which are brought into milk at an early age (about 2 years and 9 months), and sold in their prime as cows. The milk is good—about 720 gallons. The farmer is a most optimistic and of the good health of the cows. Perhaps the most novel feature is that instead of bringing in the cows to be milked in sheds a movable milking establishment is taken to them. It is moved about to suit the herds and to ensure equal distribution of manure and the treading of the soil that is so effective in breaking up the matted covering of old grass on the surface. By this plan, moreover, the cost of carting manure is saved. No pails are used and the cows are milked by a machine; provision for the cleaning and sterilizing of the milking apparatus, and the pipes through which the milk passes to the churns, is part of the movable establishment. The cows, enticed by their customary ration of cake, come at stated times into a sort of compound and there they take their turn in the milking stalls. They receive their allowance of cake while the milking machine is drawing the milk from them. They are given 4 lb. of concentrates to a gallon of milk, and in winter at the rate of 14 lb. of hay a day. For ease of feeding the hayricks are built in the middle of the fields.

Mr. Hosier attributes the exceptional health of his cows in winter to the altitude of their pastures (up to 870 ft. above the sea), which are above the mists and fogs of the valleys. The farm is now carrying 500 cattle, including 180 cows in milk. The number of cattle could be increased by 100, and probably will be next year. In that case the number of cattle on the farm will be very likely as large as that of the sheep formerly maintained on the same area. The experiment is of great interest to agriculturists, but many of the details essential to follow are not here mentioned. It is of great interest to the public health, for it is the last word in the matter, and so far as experience at present goes, it is a success.

#### CURIOSITIES OF MEDICAL HISTORY.

DR. DAN MCKENZIE is already well known as a graceful writer on non-medical as well as professional themes. His latest contribution is a paper on some curiosities of medical history—the Newcastle-on-Tyne and Northumberland last December, which will not far from paper he propounded sixteen questions on medical folk-lore, some of which he discussed in detail. It is interesting to see that in answering the question, "Why ground skull bone cures epilepsy?" Dr. McKenzie quotes Paracelsus as saying: "There is a bone in the head called the centrum. If it is drunk it cures the disease. This bone is not more than a kreutzer broad; it is somewhat angular, bifid posteriorly, and is not found in the skull." This bone, according to Dr. McKenzie, is obviously the vomer. Perhaps such an interpretation comes naturally to a rhinologist, but to us it seems rather far-fetched. The avers student usually finds the vomer an elusive bone, and we can think that it was likely to be chosen as a charm in the days of Paracelsus. Certainly it could not be used as an antiseptic medicament. Would not the description apply better to one of the ossa triquetra or wormian bones, whose situation lies open to operation in the living by so-called trephining or scraping? We offer this suggestion to Dr. McKenzie with due diffidence. The editor of a medical journal in the past seems to have treated him badly and exposed his own ignorance when he wrote on the margin of a rejected contribution, "Never heard of such doctrine," apropos of the doctrine of signatures. We thank Dr. McKenzie that we are not as other editors may have been, for we discuss the doctrine of signatures in a leading article on August 11th 1923. One more criticism is suggested by this interesting paper. In discussing what happened to the Assyrian who came down like a wolf on the fold, the meaning of the word *emerod* comes in question. The Oxford Dictionary gives *haemorrhoid* as the modern equivalent, but to make a convincing golden image, a pile, whether internal or external, would seem a task of some difficulty. Dr. McKenzie accepts the suggestion that the *emerods* were really plague buboes, but it would not be easy to make recognizable images even of these. The origin and purpose of ritual circumcision, the powers of fasting, spittle, and the Hawaiian god of abortion, are some of the other topics treated in this paper. "Quot homines, tot sententiae" might well be expanded into "So many countries, so many beliefs." To suppose upon a person is in Europe a contemptuous insult and a breach of good manners, yet in some African tribes it is a mark of friendship and high esteem, for

"... the world is wondrous large—seven seas from marae to marae—  
And it holds a vast of various kinds of man;  
And the wildest dreams of Kew are the facts of Khatmandhu,  
And the crimes of Clapham chaste in Martaban."

#### CHILD WELFARE IN THE UNITED STATES.

THE national importance of paying attention to the health of infants and children received further practical recognition in the United States in 1919, when a division of the State Board of Health was created to deal with child hygiene. In 1921, with the passing of the Federal Maternity and Infancy Act, Federal aid became available for those States—forty-four out of forty-nine—which accepted the provisions of what is known as the Sheppard-Towner Act. The issue of the *Medical Woman's Journal* (Cincinnati) for June contains the first instalment of a series of articles on the work in the various States under this Act, which encourages the study of the causes of infantile mortality and the control of the diseases of infancy and childhood. The report of the work in Missouri shows that birth registration has been considerably improved, and that demonstrations and conferences have been arranged in ninety-seven counties of this State, where an appeal is being made for a full-time health service. There has been a decline in the infantile mortality from 82 per 1,000 live births in 1919 to 69 in 1924. In Rhode Island a systematic follow-up of the infants from birth to 5 years is being organized and pre-natal classes are being extensively held. The *Medical Woman's Journal*, which appears monthly, is devoted primarily to recording the work of medical women throughout the world, and the June issue includes reports on the American Hospital in Paris, and the twelfth annual convention of the Medical Women's Association, including its work in Russia, Greece, Serbia, Japan, and Mexico.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 30, 31, 34, and 35 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 32 and 33. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 112.

# A British Medical Association Lecture ON THE MECHANISM OF INHERITANCE.

GIVEN TO THE DUNDEE BRANCH.

BY

F. A. E. CREW, M.D., D.Sc., Ph.D., F.R.S.Ed.,  
ANIMAL BREEDING RESEARCH DEPARTMENT, UNIVERSITY OF EDINBURGH.

As the facts concerning inheritance, secured by observation, accumulated, it came to be noted that in them could be recognized an orderliness, an interrelationship. It was then inevitable that the human mind, in its inherent desire to trace and describe order in nature, should seek some mechanism that in its working could account for these facts. So the idea of an "idioplasm" (Nägeli and others), a special substance the function of which was to transmit and control the hereditary characters, details of form and of function, in the developing individual came into being. This idioplasm remained a purely theoretical conception until Wilhelm Roux (1883), out of his work on cell division, was able to point out that many of the functions of this hypothetical substance could be performed efficiently by the nuclear chromatin. Upon this suggestion Weismann (1886, 1894) modelled his theory of the germ-plasm; but inspiring as his hypothesis was, it was constructed at a time when knowledge of the essential organization of the cell was still incomplete and insufficient. Since that time, however, a considerable body of knowledge concerning the cell has emerged from investigations in cytology, microdissection, and tissue culture, and to-day there exists a very clear picture of the living cell which allows the statement to be made with a certain degree of confidence that the chromosomes, because they most nearly satisfy the demands made upon the mechanism of inheritance by the accumulated facts of experimental breeding, are to be regarded as this idioplasm. It can be shown that the only identifiable cell organs that can satisfy these demands are the chromosomes; in their behaviour is realized the precise conditions of hereditary transmission demanded by the results of countless breeding experiments. The theory relating to the functions of the chromatin in inheritance is known as the chromosome theory of heredity.

Of the characters of the living organism known to be hereditary there are two classes—those in which the mode of inheritance has been amply demonstrated, and those as to which 'sufficient' knowledge is as yet not available. Critically controlled experimentation soon demonstrated that the inheritance of characters was not haphazard, but subject to definite rules or laws. It also quickly became apparent that the most striking fact which emerged from a survey of these laws of inheritance was that they applied with equal force to all sorts of living things, that laws established from a study of one organism applied with minor, often readily interpretable, exceptions to all the rest. It can be stated that the principles established by a study of experimentally convenient animals may be applied with success to forms with which, because of various practical difficulties, there has been as yet insufficient experimentation. Man, exceptional in many ways, is essentially similar to those forms of life with which the geneticist has worked; in fact, investigation has already shown that many of his characters—morphological, physiological, psychological—are subject to the universal laws of inheritance. Knowledge of inheritance in the human is essential for accurate diagnosis and prognosis in medicine, and must become the basis for any sound and scientific effort in racial improvement. Problems of human inheritance must be studied by somewhat different methods from those employed in the case of the ordinary experimental stocks. Direct experimentation is impracticable, and the only method now available is that of collecting and analysing sufficient data gleaned from family histories. For examples that clearly illustrate the fundamental orderliness and precision in the transmission of hereditary characters it is desirable to turn to the usual experimental

materials of the geneticist. Examples of similar modes of inheritance in the case of human characters are abundant.

It is most convenient to call upon the Dipteran, *Drosophila melanogaster*, the fruit-fly, for illustrations of the different modes of inheritance of characters, for the reason that to its study we owe most of our knowledge of the hereditary mechanism.

(A) If as a parental generation ( $P_1$ ) a fly with the wild type "long" wings is mated to one with vestigial wings (this character, "vestigial wing form," appeared as a sport or mutation in a long-winged stock) the first filial generation ( $F_1$ ) are all long-winged. The character "long-winged" is dominant and in relation to it vestigial is recessive. If these  $F_1$  long-winged flies are interbred they will produce a second filial generation ( $F_2$ ) which includes two classes of flies in respect of wing form—long-winged and vestigial—and in every four on the average there will be three of the former to one of the latter.

(B) If a vestigial-winged fly with the wild-type body coloration grey is mated with a long-winged ebony-coloured fly (the ebony coloration appeared as a mutation in a grey stock) the  $F_1$  flies will all be long-winged greys (grey is dominant to ebony). They will exhibit the two dominant members of the two contrasted pairs of characters. If these  $F_1$  flies are interbred they will produce four classes of offspring in  $F_2$ —long-winged greys, long-winged ebones, vestigial greys, and vestigial ebones—and in every sixteen, on the average, these four classes will appear in the relative proportions of 9 : 3 : 3 : 1. It is to be noted that the two characters of respective parents, vestigial grey and long-winged ebony, have become dissociated and recombined.

(C) If a long-winged grey  $F_1$  male out of the mating vestigial grey and long-winged ebony is mated with a vestigial ebony female, there will be produced four classes of offspring in equal numbers—long-winged greys, long-winged ebones, vestigial greys, and vestigial ebones.

(D) If a vestigial black fly (not ebony, but another mutant character very similar on inspection) is mated with a long-winged grey, all the individuals of the  $F_1$  generation will exhibit the two dominant characters—long-winged and grey. If a male of this generation is mated to a vestigial black female (that is, one exhibiting the two recessive characters), only two classes of offspring will appear—vestigial blacks and long-winged greys—and these will be produced in equal numbers. It will be noticed that the character associations in this generation are exactly those that were exhibited by the two flies with which the experiment started.

(E) If instead of the  $F_1$  male (as in D) an  $F_1$  long-winged grey female is mated to a vestigial black male, then four classes of offspring will be produced, not two as in (D), and not in equal numbers as in (C), but in the following relative proportions: long-winged greys 41.5 per cent.; vestigial blacks 41.5; long-winged blacks 8.5; and vestigial greys 8.5. It is to be noted that this result differs from that in (D) in that there is a dissociation and recombination of characters, but only to a certain limited extent.

(F) If a white-eyed male is mated to a (wild type) red-eyed female, all the  $F_1$  males and females, alike, will be red-eyed, and if these  $F_1$  individuals are interbred the  $F_2$  will consist of three reds to one white in every four on the average (see A); but all the white-eyed individuals will be males. The recessive character of a grandfather is exhibited by none of his children, by none of his granddaughters, and by only 50 per cent. of his grandsons.

(G) If, on the other hand, a red-eyed male is mated to a white-eyed female, then all the males of  $F_1$  will exhibit the white-eye character of their mother, whereas all the  $F_1$  females will exhibit the red-eye character of their father. There will be criss-cross inheritance, sons "taking after" their mother, daughters after their father.

These are the main modes of inheritance that have to be accommodated by the hereditary mechanism. It is now to be shown how the chromosome mechanism can accommodate them. From a consideration of these facts there can emerge an appreciation of the exact demands that must be made upon the hereditary mechanism. The chromosomes in their architecture and behaviour must be examined in the light of these demands.

In medical practice the questions that are asked and have to be answered are these: If an individual with a certain characterization marries and has children, will these be normal? How is it that to perfectly normal parents a child with a peculiar characterization is born?

The geneticist is not concerned with the nature of a character, whether it is helpful or harmful; he is concerned solely with the mode of its inheritance. If accurate pedigrees are available, it is usually a simple matter to answer these questions. Most of the human characters so far investigated belong either to type (A) or (F) or (G) above. If it is established that a certain character, such as brachydactyly or diabetes insipidus, is a simple dominant, or that it is sex-linked as in (F) and (G)—for example, haemophilia or colour-blindness—reference to the interpretations given in this paper will enable the practitioner to predict and to explain.

It is to be stated that even yet there exists but little definite knowledge concerning the chemical nature of chromatin; it is known, however, that it is intimately related to the activities of the cell as a whole; that it has a definite architecture and disposition within the nucleus; that it is a semifluid colloid which undergoes gelations and liquefactions of a limited and definite order, and is continuous with the nuclear matrix and thence with the cytoplasm. It is known that during mitosis the chromatin becomes condensed and homogeneous and then displays most clearly the nature of its organization into units, the chromosomes. It is established that the number, size, form, and behaviour of the chromosomes are constant in a species and are characteristic of that species (Fig. 1). It

FIG. 1.—The chromosomes of man. (After Painter.)

is known that even when the chromatin is thus condensed in the form of chromosomes it still retains its organic contact with the non-chromatinic part of the cell of which it is but a part, though an essential part. It is to be understood that the modern theory of inheritance does not require a special idioplasm concerned solely with hereditary transmission. Reproduction is a function of the cell as a whole, dependent, however, like all its other properties, upon the presence of nuclear chromatin. However, it can be stated that all the evidence there is points to the fact that in the gamete the chromatin alone possesses those attributes of constancy of proportion and behaviour which would appear to be necessary to satisfy the theoretical requirements of an idioplasm. It will be noted that among the bisexual species reproduction is effected by the combined activities of two sexually differentiated parents, each of which contributes to the new individual but a single cell. Yet these gametes, which in their union form the zygote in which the new individual has its being, constitute the only material link between the generations, the narrow bridge across which all the organic inheritance must pass. The fertilized ovum is a new individual, specific to the highest degree, embodying all the possibilities of individual development and racial perpetuation. In certain favourable cases (such as that of *Ascaris megalocephala*, Boveri) it has been possible to trace back in a continuous series to the fertilized ovum in which all the cells of the body have their origin the gametes elaborated by that particular individual. There is a definite cellular continuity through all cell generations.

There are four pairs of homologous chromosomes in the body cells and immature gametes of *Drosophila melanogaster*, the members of any one pair being identical in size and shape (with the exception about to be stated). In the ripe gamete, egg or sperm, there are four single chromosomes, and because the chromosomes of the different homologous pairs differ one from the other in their size, shape, and relative position, it can be demonstrated that in the ripe gamete there is present one member of each pair, and that in the fertilized egg the diploid (double) number

is restored, and that of each reconstructed pair one member has been brought into the zygote by the sperm, the other by the egg. In respect of its chromosomes, the new individual receives from each of its parents one member of each homologous pair.

The chromosome picture differs in the two sexes. In the tissues of the female the members of each pair of chromosomes are identical. In the case of the male tissues one member of one pair is exactly similar in form, size, and disposition to the two members of the corresponding pair in the female, but its mate is unequal, is dissimilar. Since in respect of this pair the sexes differ, these chromosomes in the two sexes are referred to as the sex-chromosomes. The three chromosomes that are alike, two in the female and one in the male, are referred to, for descriptive purposes, as the X-chromosomes; the unequal mate of the X in the male is known as the Y-chromosome. Since of each pair of chromosomes only one can be present in the ripe gamete, then in respect of the sex-chromosomes all eggs must be alike, each containing an X, whereas there will be two sorts of sperm—the X-chromosome-bearing and the Y-chromosome-bearing. If an X-bearing egg is fertilized by an X-bearing sperm, an XX-bearing zygote will result. The male is digametic, the female monogametic in *Drosophila*, as also in man. The XX type of chromosome content is the female. If an X-bearing egg is fertilized by a Y-bearing sperm an XY type of individual will result, and this constitution is typical of the male. Here, then, is a simple and satisfactory self-perpetuating sex-determining mechanism.

FIG. 2.—Conventional diagram of the chromosomes of *Drosophila*. (After Morgan.)

The 3:1 ratio in the  $F_2$  of an experiment such as that dealt with in (A) above can be explained if the following assumptions are made. The chromosomes are the idioplasm. In them are resident the agents or factors or genes which in their action determine the future characterization of the individual, controlling the differentiation of the organs and tissues during ontogeny. There is a gene for long-winged and another gene for vestigial, but only one of these can be present at any one time in the particular chromosome that carries them. In each of the chromosomes of a particular pair in the long-winged race there is a gene corresponding to the character long-winged; in the case of the vestigial race there is instead a gene for vestigial. In respect of this same pair of chromosomes the  $F_1$  individual will have received one from each parent; each will carry the factor for long-winged in one chromosome of a pair, the factor for vestigial in the other. Why one gene in its action dominates the other we do not know; the observed fact is that in their relationship to vestigial and long-winged the latter is dominant. When these  $F_1$  individuals elaborate their gametes, into each passes either the chromosome bearing the gene for long-winged or else the chromosomes bearing the gene for vestigial. If there are equal numbers of the two sorts of eggs and equal numbers of the two sorts of sperm, and if fertilization is at random, the following chromosome associations will result, and the four sorts will be equally frequent:—long-winged : long-winged; long-winged : vestigial; vestigial : long-winged; and vestigial : vestigial. Since the character long-winged is dominant to vestigial, there will be on the average in every four three long-winged flies to each vestigial in  $F_2$ .

FIG. 3.—The chromosome interpretation of a monohybrid experiment.

The 9:3:3:1 ratio in (B) above can be explained if it is assumed that the genes for the body colour characters, grey and ebony, are not resident in the same chromosome pair as are those for vestigial and long-winged (E=the gene for grey; e that for ebony). Grey and ebony

in their relations to each other are exactly similar to long-winged and vestigial. Grey is dominant, and in the  $F_2$  of a grey by ebony mating there are three greys to each ebony on the average in every four.

FIG. 4.—The chromosome interpretation of a dihybrid experiment.

Any zygote with the genes—  
V and E will be long-winged grey — 9  
V but not E will be long-winged ebony — 3  
E but not v will be vestigial grey — 3  
Without E and V will be vestigial ebony — 1

The results obtained in (C) can be explained just as simply as seen in Fig. 5. The sperms of the male will be

FIG. 5.—The chromosome interpretation of a back cross, showing free assortment.

of four sorts (as above) and they will be produced in equal numbers. All the gametes of the female will be alike in respect of the genes for vestigial and ebony. It follows, then, that since vestigial ebony are recessive characters, the number and proportion of the classes in the resulting generation are predetermined by the number and proportion of the different sorts of sperm elaborated by the male.

VvEo ... Long-winged greys ... 25 per cent.  
Vveo ... Long-winged ebones... 25 per cent.  
vvEo ... Vestigial greys ... 25 per cent.  
vveo ... Vestigial ebones ... 25 per cent.

It will be recognized that so long as there are as many chromosomes as there are independently heritable characters there is no difficulty in accounting for the mode

of their transmission, as will be seen from the following table.

| No. of chromosomes in the gamete (the haploid number) | No. of possible combinations of maternal and paternal chromosomes in the zygote. |
|---|--|
| 1   | 4  |
| 2   | 16   |
| 3   | 64   |
| 4   | 256  |
| 5   | 1,024  |
| 6   | 4,096  |
| 7   | 16,384   |
| 8   | 65,536   |
| 9   | 262,144  |
| 10  | 1,048,576  |

In the case of the human there are twenty-four chromosomes in the gamete, so that it can be seen that infinite variety in the zygote is possible, even though only one gene were borne on one chromosome.

In *Drosophila* there are many hundreds of characters that can be paired off in the same way as vestigial and long-winged, grey body colour and ebony, yet in each gamete there are four chromosomes to bear their genes. It follows that either the chromosome hypothesis fails to satisfy the demands made upon it, or else more than one gene is resident in one and the same chromosome. If the genes for several different characters are resident in one and the same chromosome, then if that chromosome preserves its integrity during its transference from cell to cell the characters corresponding to the genes resident therein should be transmitted together and should remain linked in inheritance.

FIG. 6.—The chromosome interpretation of a back cross, showing linkage.

If the genes for black and vestigial are resident in one and the same chromosome, then the results obtained in (D) above can be interpreted.  $FR_1$  is a symbol indicating that an  $F_1$  individual is backcrossed to a recessive.  $FR_2$  represents the resulting generation.

It has been found that all the characters so far examined in *Drosophila* fall into four groups. The members of any one group give this 50 per cent. : 50 per cent. ratio when any pair of them are involved in a breeding test similar to that above; but when any one of them is associated with a member of any other group the result is a 25:25:25:25 ratio, similar to that in the vestigial-ebony experiment described above. There are four linkage groups, and four chromosomes. It is reasonable to argue that upon a particular chromosome are resident the genes of a particular group of characters. More will be said of this conception later.

In (E) it is seen that this 50:50 ratio is not obtained when an  $F_1$  female is mated with the double recessive. It will be agreed that the reason for the production of four classes of offspring instead of two must be that the  $F_1$  female elaborated four sorts of eggs instead of two, for the sperm of the double recessive male are all alike, and since the characters vestigial and black are recessive, they will not disguise the results. The classes and the proportion of these can be explained if the  $F_1$  female elaborated the following kinds of eggs in the proportions suggested.

|      |      |     |     |   |   |   |   |
|------|------|-----|-----|---|---|---|---|
| B    | V    | b   | v   | B | v | b | v |
| 41.5 | 41.5 | 8.5 | 8.5 |   |   |   |   |

In order that these four sorts shall be elaborated in these proportions, it is necessary that in the maturation of 17 per cent. of the eggs there shall be an interchange of chromatin between the chromosome B-V and b-v in such a way that the part of the one chromosome carrying the gene B shall be detached from the rest carrying V; that the parts of the other chromosome shall be similarly separated; and

that these chromosomes shall then reunite in such a way that part of one unites with part of the other, as in D of Fig. 7. It will be noted that interchange leads to

FIG. 7.—Crossing-over.

significant results only when the chromosomes concerned are dissimilar in their genetic constitution. It is in the case of the "heterozygous" female that crossing-over leads to the production of recombination classes. For reasons at present unknown crossing-over does not occur in the case of the digametic sex of *Drosophila*, though it does in other forms.

The two new combinations after the interchange has taken place show again the same linkage relations to each other as did the former associations, showing that the linkage relation is independent of the characters that form the combination. Linkage between black and vestigial is exactly similar to that between grey and vestigial, and between black and long-winged. Such an interchange of chromatin between the two members of a pair of homologous chromosomes is known as crossing-over, and the percentage of the recombination or cross-over classes is referred to as the crossing-over value (C.O.V.), whilst the linkage between two genes is expressed by the percentage of cases in which they remain together. If the linkage in a particular case is 50 per cent. and the C.O.V. 50 per cent., the result would exactly simulate the effects of free assortment giving a 25:25:25:25 per cent. ratio. As a matter of fact, this situation has not arisen in the case of *Drosophila*, being prevented by the occurrence of double crossing-over, fracture and reunion at two points in the chromosome some distance one from the other.

It will have been recognized that this theory of inheritance, like many of its predecessors, postulates the existence of a number of individual particles of substance each of which controls the development of some particular tissue or character in the developing organism. Like the gemmules of Darwin, the biophors of Weismann, the physiological units of Spencer, the pangens of de Vries, the genes of Morgan are required to be minute yet distinct units of, or areas in, the chromatin. It is, therefore, of profound interest to know that the chromosomes are indeed made up of small aggregates, the chromomeres. It has been established in favourable cases that a particular chromosome always exhibits the same series of chromomeres in any stage when they can be identified. Wenrich (1916) in the grasshopper (*Phrynotettix magnus*) has shown that any particular chromosome, to be recognized by its

distinctive shape, size, and behaviour, is built up of a definite number of chromomeres, and that these are to be individually recognized by constant differences in form and relative position. The chromosome has a definite and constant organization.

The fact that the chromomeres are arranged in the chromosome in a linear series and that each chromomere has its own particular place or locus in this series is of prime importance in the interpretation of linkage and crossing-over.

During the maturation divisions in the production of the gametes the segregation of homologous chromosomes is complicated by the fact that the members of each pair, prior to their separation, become most intimately intertwined. This apparently single but really double chromosome then splits longitudinally. This conjugation of homologous chromosomes provides the opportunity for

crossing-over. It cannot be shown to have occurred, but if during this conjugation the two chromosomes stick, fracture, and rejoin before separation, then interchange of chromatin will have occurred. It is not without significance that conjugation occurs when the chromosomes are drawn out to their greatest attenuation so that the homologous chromomeres derived from the two parents achieve the maximum degree of association in a linear series. It is seen that the equivalent chromosome contributions of the two parents and their random assortment in maturation and chance recombination in fertilization, together with the possibility of an inner reorganization of each chromosome through its most intimate association with another of identical structure but different content, provide an infinite range of new combinations of characters which can be tested out by environmental agencies. The chromosome mechanism can supply the variations upon which the forces of selection can operate. - It becomes apparent also that this conjugation of chromosomes in synapsis excludes the possibility of fruitful crosses between species widely different in chromosome constitution.

If the conjugation of homologous chromosomes is accepted as evidence in support of the conception of crossing-over, and if the genes are strung like beads upon a string, each particular gene having its own particular locus upon a particular chromosome, then it follows that the percentage of crossing-over between any two loci can be regarded as an indication of the distance between them. If the members of a pair of homologous chromosomes during their conjugation are as likely to fracture and reunite at one point as at any other point along their length, it follows that the further apart any two genes lie in the chromosome, the greater is the chance of crossing-over occurring; and conversely, the nearer together the genes lie, the smaller is the chance of crossing-over occurring. If this is so, then it is possible to construct a map of the chromosomes, showing the relative positions of the different genes resident in each. If A, B, and C form a linear series, and if B lies between A and C, then the crossing-over percentage occurring between A and C should equal the sum of the C.O.V.'s between A and B, B and C. The conception of the localization of the genes in linear alignment is due to the peculiar differences between the C.O.V. between genes of the same character linkage group. The relation of three or more points to each other is a relation of linear order and cannot be represented in space in any other manner than by a series of points arranged in a line. The linear order of the chromomeres is established beyond question. Linearity is the expression of a system in which there is a fixed succession of elements. The distance between any two elements is constant, but is variable throughout the series. In the case of the more simply organized forms of life it is possible to conceive the idioplasm having the form of a congeries of chromatin units, the members of which can exist separately within the nucleus and become associated by chance. In the more complex forms, however, the precision exhibited in the inheritance of a most complicated characterization demands a very precise and more complex hereditary mechanism, such as is supplied by the chromosomes in their constitution and behaviour.

In order to learn how the chromosome map is made, let us assume, for example, that the character Dachs (short legs) appears as a mutation in a stock of *Drosophila*. Breeding experiments show that it is an hereditary character, for when mated with the wild type it gives a 3:1 ratio in  $F_2$ . We then, let us say, mate a black normal-legged individual with the new form, grey Dachs, to get an  $F_1$ . The  $F_1$  male is then back-crossed with a double recessive female, and we get a 50:50 ratio. We then know that Dachs belongs to the same linkage group as does black. The  $F_1$  female then back-crossed with a double recessive male gives black normal-legged 41.25, grey Dachs 41.25, black Dachs 8.75, grey normal-legged 8.75 per cent. The C.O.V. between Dachs and black is 17.5 per cent. We already know that the C.O.V. between black and vestigial is 17 per cent. We can, therefore, anticipate that the C.O.V. between Dachs and vestigial will be either 0.5 or 34.5 per cent., the actual figure being decided by the relative positions of the three genes. If a Dachs long-winged

FIG. 8.—Chromomeres in linear series. Conjugating chromosomes of the mar-supial *Petaurroides*. (After Agar.)

fly is mated with a normal-legged vestigial, and the  $F_1$  male mated to the double recessive female, a 50:50 ratio will be obtained. Dachs is in the same linkage group as vestigial. If the  $F_1$  female is mated with the double recessive, it is found that the C.O.V. between Dachs and vestigial is 34.5 per cent. It can now be stated that the relative positions of Dachs, black, and vestigial are in the order given, black coming between the other two almost exactly midway.

FIG. 9.—Chromosome interpretation of sex-linked inheritance.

FIG. 10.—The reciprocal cross giving "criss-cross" inheritance.

One per cent. of crossing-over is taken as the unit for expressing linkage relations. This unit can be represented in a diagrammatic map of the chromosomes as 1 cm. or any other convenient size. A line is drawn to represent the position of the gene for black. Seventeen units of distance to one side of it another mark is made for the gene for vestigial, and 17.5 units to the other side of it the mark for the gene for Dachs is made. The making of the map is begun. Some 107 genes require to be placed in this chromosome. Their characters all show linkage with black and vestigial and Dachs, and with each other, and the C.O.V. between any two of them is characteristic. Out of crossing-over work with them it is soon possible to arrange them all in their proper order. In the other linkage groups of *Drosophila* there are 70, 106, and 3 characters respectively. This map gives to the breeder those powers which are possessed by the synthetic chemist in the manipulation of his materials. It can be compared to a railway time-table which shows the sequence of the stations and the distance between them.

All that remains is to show which particular chromosome carries the genes for a certain character linkage group.

A consideration of the facts related in (F) and (G) will lead to the conclusion that the characters red and white eye are being transmitted from generation to generation by some mechanism which is also concerned in the determination of the sex of an individual, and that the simplest interpretation of the facts can be made if it is assumed that the male, in respect of the elements of the sex-determining mechanism, elaborates two sorts of sperm—one, the X-chromosome-bearing, the other the Y-chromosome-bearing. If it is assumed that in the X-chromosome are resident the genes for those characters that in their inheritance behave as does white-eye, being sex-linked, and that in the Y-chromosome there are no genes, the facts can be accommodated. In Diagram 9 the solid chromosome is the X carrying the gene for red-eye, the open one the X carrying the gene for white-eye; XX is a female, XY a male; red is dominant to white.

Other evidence exists which demonstrates that the X-chromosome is concerned in the transmission of the sex-linked characters. It has been shown that when a white-eyed female is mated with a red-eyed male, criss-cross inheritance is observed, the daughters being red-eyed like their father, the sons white-eyed like their mother; and it has been shown further that this type of inheritance can

be explained perfectly satisfactorily on the assumption that in the single X-chromosome of the father there is resident the gene for red-eye, and that in each of the X-chromosomes of the mother there is a gene for white-eye, that red is dominant to white, and that the male is digametic, the female monogametic. (Fig. 9A.) It so happened that Bridges found in his stocks exceptions to this rule, and it was not until the chromosome constitution of the individuals concerned was examined that the exceptional cases could be explained.

During the maturation of the egg the two X-chromosomes, like the members of every other pair of homologous chromosomes, disjoin, one passing into the polar body, the other remaining in the ovum. If the X-chromosomes of a white-eyed female failed to disjoin two sorts of egg would result, one containing two X-chromosomes and the other without an X-chromosome. If the XX egg is fertilized by a Y-bearing sperm, an individual with an XXY sex-chromosome constitution would result. This has been shown to be the case, and the individual looks like and functions as a female. If this non-disjunctive XXY white-eyed female is used, instead of the ordinary XX female, exceptional results will ensue.

Bridges was able to explain all his exceptions to the rule of criss-cross inheritance by reference to the sex-chromosome constitutions of the individuals. The exceptional white-eyed daughters are white-eyed because they do not get one of their X-chromosomes from their red-eyed father; the exceptional red-eyed sons are red-eyed because they get their X-chromosome from their father, whereas normally the son gets his Y-chromosome from this source.

It can be accepted that the X-chromosome (chromosome I) bears the genes of the sex-linked group of characters. It can be shown that the small, round, centrally placed chromosome (chromosome IV) carries the genes for another group of linked characters. Individuals with but a single IVth chromosome (Haplo-IVs) and others with three instead of two (Triplo-IVs) have been identified, and these abnormalities in chromosome number are associated with definite abnormalities in general characterization. On chromosome II, one of the larger boomerang-shaped chromosomes, are placed the genes of the characters linked with black; on the other large curved chromosome, chromosome III, those linked with Star.

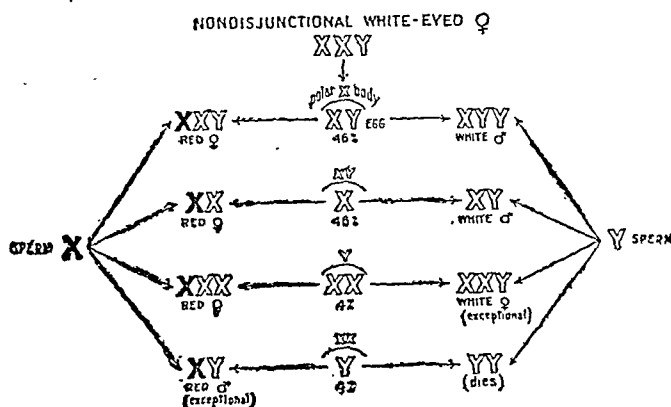

FIG. 10.—Non-disjunction. Chromosome interpretation of exceptional sex-linked results. (After Morgan.)

The story that I have endeavoured to tell is but a brief outline. I have told it because I know of its interest and am convinced of its usefulness. It is desirable, in my opinion, that the medical man should be well acquainted with the principles of the science of genetics, which will give to him a better understanding of his many and varied problems. If I have aroused your interest, I may hope that you will seek further information from the masters at whose feet I am so proud to sit.

## British Medical Association.

PROCEEDINGS OF SECTIONS AT THE ANNUAL  
MEETING, NOTTINGHAM, 1926.SECTIONS OF ANAESTHETICS AND  
SURGERY.

SAMUEL JOHNSTON, M.D., C.M., F.A.C.P., in the chair.

At the invitation of Sir James Berry, President of the Section of Surgery, Dr. Samuel Johnston, President of the Section of Anaesthetics, took the chair, and, expressing his appreciation, said that for once there could be an association of surgery with anaesthesia without the question of sufficient relaxation arising.

DISCUSSION ON  
ANAESTHESIA IN ABDOMINAL SURGERY.

## OPENING PAPERS.

I.—PROFESSOR H. FINSTERER,  
Vienna.

WHEN I received the invitation to read the opening paper on anaesthesia in abdominal surgery at the combined meeting of the Sections of Anaesthetics and Surgery of the British Medical Association I felt highly honoured, but at the same time I had great doubts as to being able to carry out the task, on account of my inadequate knowledge of the English language, and for this I must ask your consideration. In the first place, I beg to tender my warmest thanks to the President, Mr. Hogarth, for the invitation, which I regard as a great honour and distinction, and I beg to thank the secretaries of the Surgical Section for the interest they showed in operations under splanchnic anaesthesia on their visits to Vienna. I think it is due to their influence that this important theme was suggested for this combined session.

In abdominal surgery anaesthesia is of greater importance than in operations on the extremities, for through diseases of the abdominal organs, such as acute appendicitis or cholelithiasis, serious changes in the liver are caused, so that a complete anaesthesia with chloroform or ether, by which the liver is affected, may cause fatal hepatic insufficiency, which in cases of operations on the extremities is not to be feared. If the power of resistance of the peritoneum is weakened by a prolonged deep narcosis, the infection of the abdominal cavity, possible in every abdominal operation, can more easily lead to fatal peritonitis. Finally, many abdominal operations, such as radical operations for gastro-jejunal ulcer, belong to the greatest and most difficult operations, in which death from shock is to be feared. In view of this, every endeavour to improve anaesthesia in abdominal surgery is justified. Since it is impossible in this small paper to discuss the development of all the methods of anaesthesia, I will devote myself more particularly to the most important.

Naturally during my experience I have used all methods of anaesthesia for abdominal surgery, but for many years I have practically employed only the regional and the combined methods. I am so convinced of the advantages of combined and regional anaesthesia over general anaesthesia that I do not now operate on patients who insist upon a general anaesthetic. The methods of anaesthesia can be classified into three groups:

**A. General Anaesthesia.**—The whole operation is completed while the patient is unconscious and the anaesthesia occurs *exclusively* in the cerebrum.

**B. Combined Anaesthesia.**—Pain is eliminated partly as a result of interruption of the sensory nerves and partly through unconsciousness during part of the operation as a result of temporary exclusion of the cerebrum, through general narcosis.

**C. Regional Anaesthesia.**—The conduction of pain is interrupted by injecting effective drugs near the sensory

nerves, but consciousness is unaffected. This interruption may be effected (1) in the spinal canal (spinal anaesthesia); (2) near the spinal column (paravertebral, parasacral anaesthesia); or (3) the splanchnic nerves themselves (splanchnic anaesthesia) or their branches in the mesenteries (mesenteric anaesthesia) can be blocked.

## A. GENERAL ANAESTHESIA.

Ether and chloroform, alone or mixed, are commonly used to-day. Chloroform is gradually being used less frequently because of its injurious effect upon the parenchymatous organs (liver, heart, kidney).

The advantages of general narcosis are: complete loss of consciousness, which is of great importance in nervous patients; complete muscular relaxation with the associated greater ease in laparotomies; and the ability to examine the entire peritoneal cavity for diagnostic purposes.

The unfavourable features of general anaesthesia are:

1. *Primary danger of the anaesthetic*—death during the narcosis; but in the hands of a trained anaesthetist and with the use of ether this is no longer to be feared.

2. *The drop in blood pressure* which results both from the action of the anaesthetic upon the vasomotor centre and from the injuries to the heart musculature. This fall in blood pressure is of extreme danger inasmuch as the blood pressure, which may be already low as a result of disease (peritonitis or intestinal obstruction), is further decreased as the result of the loss of the intra-abdominal pressure secondary to eventration of some of the intestinal loops.

3. As already shown by Crile, in general narcosis the conduction of pain to the cerebrum is not interrupted, and this fact leads to marked changes in the higher brain centres. These changes (confirmed by Crile) and the increased hydrogen-ion content of the blood (acidosis) are the causes of the so-called "operative shock."

4. *Injuries of the parenchymatous organs.* The narcotizing agent which is absorbed in the blood not only injures the brain, but also the liver, heart, kidney, adrenal, etc. This injury rapidly disappears in healthy organs after the cessation of the narcosis, but in diseased organs this damage may lead to an insufficiency, especially in the heart and liver, which often terminates fatally. This injury of the liver occurs not only with chloroform but also with protracted ether narcosis; similar changes of the heart are shown by König, of the adrenals by Schur and Wiesel. These injuries are proportionate to the depth and duration of the narcosis, which in turn vary with the extent and duration of the operation. Of course, they can be diminished by sparing use of the anaesthetic by a very competent anaesthetist, but not completely eliminated.

5. *Lung complications* are increased with general narcosis. The experimental work of Snel has shown that the normal resistance of the lungs is diminished by protracted narcosis, so that pneumonia more readily occurs either from bacteria already in the alveoli of the lungs or from aspirated sputum. The ultimate outcome depends directly upon the heart, which is itself damaged by the general narcosis.

The injury to these parenchymatous organs can be diminished if less of the anaesthetic be used. This is achieved through the use of morphine or pantopon, which affect the cerebrum. Scopolamine acts as an excellent synergist, but is dangerous. Atropine decreases the secretion of the mucous membranes, and both morphine and atropine should be used together prior to every ether narcosis. The quantity should be proportioned to the strength of the patient.

To eliminate the disadvantages of general narcosis chloroform or ether is substituted by the gas anaesthetics, primarily nitrous oxide, which favourably impressed me in America. When properly used, it is practically without danger (Crile told me personally that he had no fatalities in over 50,000 cases). It does not cause a drop in blood pressure or damage to the brain, liver, etc. (as shown experimentally by Crile), and on this account it has been a marked advancement in the question of general narcosis. Its disadvantages are, that frequently there is not enough relaxation of the abdominal musculature, necessitating the associated use of ether to obtain complete relaxation. This, however, can be obtained more simply and more effectively by the injection of novocain

into the muscoli recti, through which measure nitrous oxide becomes an important agent in the so-called "combined anaesthesia."

In a similar fashion we may use ethylene, which was developed by Luckhardt. Mixed with 10 to 20 per cent. oxygen it has given a deep narcosis with marked relaxation in 100,000 cases without any bad effects on the patients. Its only disadvantages are its inflammability and explosive character. Acetylene (narcylene), whose anaesthetic qualifications were discovered by Wieland and made practical by Gauss, is equally as efficacious as ethylene. It is now used in many German clinics, as seen from papers written by Eggers, Hurler, Kurtzahn and Teichert, Philipp, Reis, Schmidt, Solbach, etc. Its greatest disadvantages—namely, its inflammability and explosiveness—can be practically eliminated by caution and use of Gauss's "rebreather." The failure to get complete muscular relaxation can be overcome by local novocain injection.

#### B. COMBINED ANAESTHESIA.

Crile's method of anoci-association is a type of combined anaesthesia in which in every laparotomy the sensory nerves are blocked central to the operative field by injection of novocain and unconsciousness is effected by using nitrous oxide. Combined anaesthesia is recommended as the method of choice by Lennander in 1901, and since then has been adopted by many surgeons (Bakes, Eiselsberg, Goullioud, Hillman and Apperly, Laewen, Wheeler, etc.). Through careful anaesthesia of the peritoneum of the anterior abdominal wall the greater part of the narcotizing agent can be avoided. The theory of Lennander, that manipulation of the mesentery is painless, is no longer accepted. The experimental work of Pannett has proved that the injection of novocain into the mesentery of animals has not only guarded against shock, but also eliminated rigidity of the abdominal musculature. Therefore with combined anaesthesia it is necessary to inject novocain also into the mesentery.

Combined anaesthesia represents a marked progressive step over general, because with its use injury to the parenchymatous organs practically disappears. For this purpose nitrous oxide or narcylene, which are completely satisfactory, may be used. Unfortunately these substances are too expensive to be used in our Austrian hospitals. This necessitates the use of ether as a supplemental agent. Ethyl chloride has also been used as a supplement to local anaesthesia by different surgeons (Braun, Payr). But it is dangerous. Fatalities are reported by Hofmann, Jaeger, Kausch, Renner, etc.

#### C. REGIONAL (LOCAL) ANAESTHESIA.

To make extensive laparotomies really painless it is necessary to anaesthetize the peritoneum of the posterior as well as the anterior abdominal wall. In stomach resections for cancer anaesthesia of the abdominal wall alone was sufficient for the painless performance of the operation in exceptional cases only, and when large doses of morphine were given. In the majority of cases ether was required after opening the peritoneal cavity ("combined anaesthesia"). Real painless resections have been possible through the injection of novocain into the mesenteries, as recommended by me in 1912, only in cases when every pull at the mesentery can be avoided. But an absolutely painless operation in every case can only be obtained when the peritoneum on the posterior abdominal wall is anaesthetized. This can be achieved by paravertebral or spinal anaesthesia.

The dangers of regional anaesthesia increase as the spinal canal is approached. Mesenteric anaesthesia is practically harmless, while with spinal anaesthesia one has to deal with the danger of cerebral anoxia. On this account Braun's advice to use as far as possible from the spinal canal should be followed. The amount and concentration of the agent used should be in proportion not only to the extent of the operation, but also to the vitality of the patient. The agent generally employed is novocain, of which on the average 200 c.cm. of 1/2 per cent. solution is used. In very cachectic and anaemic patients it is better to use 1/4 per cent., which is

also satisfactory. Tutocain has been greatly employed for the last three years in Germany. It is found to be much more effective than novocain, necessitating the use of only 1/5 to 1/8 per cent. solution. As a pre-operative measure the patients receive, one hour before operation, 0.02 gram pantopon, and then, a quarter of an hour before operation, 0.01 to 0.02 gram morphine with 0.00025 to 0.0005 gram atropine. Although scopolamine is used by many surgeons, I have not used it since I saw its use result in a fatality eighteen years ago.

In all cases of regional anaesthesia it is necessary to have a complete anaesthesia of the anterior abdominal wall. In order to obtain this, besides the external injections on the lateral border of the rectus muscle, it is advisable to inject novocain after opening the abdomen from the inside as far laterally as possible into the properitoneal tissue.

#### 1. Mesenteric Anaesthesia.

Mesenteric anaesthesia is the simplest and least dangerous method of regional anaesthesia; it is satisfactory in all cases in which all pulling can be avoided. It is entirely satisfactory in cases of resection for a movable ulcer or cancer in pitotic stomach; but when the ulcer penetrates into the pancreas a supporting narcosis is necessary. Mesenteric anaesthesia should be used in every operation begun under general narcosis in order to decrease the operative shock (Pannett).

#### 2. Paravertebral Anaesthesia.

Paravertebral anaesthesia is of advantage only in operations in which injection on one side suffices—for example, in colon resection, cholecystectomy, etc. Therefore in 1912 I advised the employment of this method in these cases only. In cases of doubtful diagnosis it is far better to infiltrate the anterior abdominal wall prior to incision, examine the abdomen under short ether or nitrous oxide narcosis, and continue the operation with mesenteric or splanchnic anaesthesia. Up to the present I have used paravertebral anaesthesia in 151 cases, and ether was necessary fourteen times. There were 49 colon resections in this series, and in 45 of these paravertebral anaesthesia was quite sufficient. Paravertebral anaesthesia cannot be adopted in all laparotomies, but will be found of great advantage in exceptional cases, such as resection of the colon, cholecystectomies, etc.

#### 3. Splanchnic Anaesthesia.

In upper abdominal surgery, instead of blocking each ramus communicans by paravertebral injection, the united nerve trunks of the splanchnic can be anaesthetized. This can be done posteriorly according to Kappis's method, or anteriorly after opening the peritoneal cavity according to Braun's method. Less commonly used are Farr's and Roussié's methods, where the splanchnics are blocked by injection of novocain into the hepatico-duodenal fossa and thus into the retroperitoneal space. The technique recommended by Roussié, in which novocain is injected into the retroperitoneal space near the superior mesenteric artery, is said to anaesthetize not only the small bowel, but also the organs innervated by the splanchnic nerves. This method is not used very much, and only 30 cases are reported by Guttierrez. Kappis's method is used in France by Billet and Laborde and by Pauchet, in England by Cade, and Hillman and Apperly. In America Labat introduced Kappis's method, and during my sojourn there in 1923 I saw that it was used almost exclusively. Only Skillern reported in 1922 that he used both the Kappis and Braun technique; and in 1923 Bland published the fact that he used Braun's method instead of that of Kappis. Since I demonstrated Braun's method it has been adopted by Beck, Burke, and Meyer. In Germany Braun's method is used, and it has recently been adopted by the clinics of Haberer and of Payr.

The Kappis method is a little more risky than Braun's technique because of the danger of intravenous and intraspinal injection. In my book on local anaesthesia in abdominal surgery (translated into English by Burke) I pointed out the possibility of lateral spinal anaesthesia. As a matter of fact, several fatalities caused by the use of Kappis's method are reported in the literature, which

are only to be explained by intravenous or intraspinal injection. With greater experience intravenous or intraspinal injection can be avoided; then this method is certainly not as dangerous as maintained by many. Kappis has personal experience with over 1,000 cases of splanchnic anaesthesia without any accident.

There is little reported in the literature about Braun's method. My personal inquiry as to the experience gained in the clinics of Braun, of Haberer, and of Payr, and the hospitals of Kirchmayr (Vienna) and Linhard (Graz) resulted in the following statistics. There is a total of 1,566 cases of splanchnic anaesthesia, of which 875 were performed by Braun, 209 by Haberer, 210 by Payr, 91 by Kirchmayr, and 181 by Linhard. In about 5 to 9 per cent. of the cases a short general narcosis with ether or ethyl chloride was necessary, but no accidents happened except in Haberer's clinic, where by mistake 1/2 per cent. instead of 1/5 per cent. tutocain solution was used; but in all these cases there was no fatality (Tschebul). In 807 cases I myself have had only one of poisoning, which was characterized by cramps, coma, and paralysis of the respiratory centres, this being the result of intravenous injection. This accident was caused by the vomiting of the patient, which moved the needle so that a part of the last 10 c.cm. was injected intravenously. This patient was revived by artificial respiration and intravenous use of lobelin. The fall in blood pressure which is reported by many authors with Kappis's method (Hillman and Apperly, Metge) is said in Braun's method not to occur in a higher degree, as shown by Buhre and Bachlechner.

As novocain is a poison, the amount and concentration must be measured according to the patient's strength. Braun uses for his splanchnic anaesthesia 100 c.cm. of 1/2 per cent. novocain or 1/4 per cent. tutocain solution, while I use on an average 70 c.cm. In cases of severe anaemia secondary to acute or chronic gastric haemorrhage, or in cases of advanced cachexia, I have used 1/4 per cent. instead of 1/2 per cent. novocain solution, and have found that 50 c.cm. will give a very satisfactory anaesthesia in most cases. In my opinion it is better in these grave cases to use a weaker solution and add ether when necessary. The ether in small amounts serves as a stimulant. Naturally, as a result of this weaker solution there is an increase in the number of cases in which ether as a supporting anaesthetic is needed.

Occasionally when it is impossible to separate the aorta from the vena cava because of firm adhesions, as in penetrating gastric ulcers, the introduction of the needle becomes either impossible or may puncture the vena cava. Then mesenteric anaesthesia must be used instead of splanchnic, and if necessary a little ether given to mobilize the stomach (combined anaesthesia). Puncture of the vena cava with a thin needle is of no significance except that, once it occurs, further attempts at splanchnic anaesthesia must be forgone, and mesenteric employed. It is very important to avoid intravenous injection and be sure of this prior to the injection of every syringe. By aspiration I assure myself that the needle point has not penetrated the vein.

My experience consists of 879 cases of splanchnic anaesthesia, of which 72 were done with Kappis's method and 807 after Braun's method. In the latter ether was used 71 times, or in 8.8 per cent., either at the beginning of the operation owing to unusual insistence of the patient, or during the operation because the anaesthesia did not last till the operation was finished. Ether is most frequently needed in cases of gastro-jejunal ulcer where strong adhesions must be separated before the splanchnic anaesthesia can be completed. The amount of ether used for the entire operation is usually very small, being as a rule 20 to 50 c.cm.; only in one case was 150 c.cm. used. These 807 cases of splanchnic anaesthesia can be subdivided as follows:

1. 112 cases of resection of the stomach for cancer, in which ether was needed 5 times.

2. 468 resections of the stomach for ulcer, ether being used 33 times.

3. 63 cases in which the stomach and gastro-intestinal anastomosis loop were resected either for an unhealed ulcer or gastro-jejunal ulcer, ether being used 25 times.

4. 89 cases of cholecystectomy or choledochotomy, ether being used 8 times.

5. 75 cases of gastro-enterostomy, exploratory laparotomy, etc., in which ether was not used.

If the amount of novocain is adjusted exactly to the patient's strength, pallor, restlessness, and air hunger, which are undesirable by-effects, can be avoided. With the use of tutocain vomiting during the operation is seen much less frequently.

Splanchnic anaesthesia is a progressive step over mesenteric anaesthesia, because through its use there is a complete anaesthesia of the peritoneum of the posterior abdominal wall. For this reason I cannot agree with Drüner that splanchnic anaesthesia is superfluous and dangerous and therefore mesenteric anaesthesia alone should be used. It is self-evident that with splanchnic anaesthesia it is impossible to explore the entire abdomen or operate in the lower abdomen, because the lumbar segment is not anaesthetized. For these purposes a short narcosis must be instituted. Meeker of the Mayo Clinic abandoned splanchnic anaesthesia after an experience of 42 cases of splanchnic anaesthesia with Kappis's technique, in which he had 38 per cent. failures, and because of its dangers. This experience is in contradistinction to the favourable results of Kappis in over 1,000 personal cases and to the good results with Braun's method in more than 2,300 cases. Even when a little ether is given in every case of splanchnic anaesthesia, as is done by Hillman and Apperly, sufficient is gained to make this "combined anaesthesia" the method of choice over general narcosis in cases of resection of the stomach.

#### 4. Parasacral Anaesthesia.

Braun's parasacral anaesthesia does not suffice for removal of the rectum, because the nerves supplying the mesosigmoid are not blocked off. This can be achieved by injecting the novocain at the base of the mesosigmoid from behind, as I described in 1922. Or it may be done during laparotomy, after opening the peritoneal cavity, through injection on the anterior surface of the fifth lumbar vertebra. Through this procedure it is possible to remove the pelvic colon by the abdomino-sacral operation without narcosis, by which the results of the operation can be considerably improved. I have used this type of parasacral anaesthesia in 38 cases of abdomino-sacral resection and needed the support of a general narcosis in 27 cases. The mortality of the abdomino-sacral operation for cancer, which in many clinics, in consequence of the numerous deaths from so-called operative shock, amounted to 60 per cent., could be considerably decreased by parasacral anaesthesia. Up to 1922 I had a relatively high mortality (19 cases, with 6 fatalities=31 per cent.), but since then I have had 20 cases with only 2 fatalities, or 10 per cent.

Although not within my field of work, I should like here to remark that, in my opinion, parasacral anaesthesia combined with injection of novocain on the front of the fifth lumbar vertebra and into the ligamentum suspensorium ovarii would be sufficient for every hysterectomy and for other gynaecological operations.

#### 5. Epidural (Sacral) Anaesthesia.

Sacral anaesthesia, which was suggested by Læwen, may be applied in operations in the true pelvis, but for laparotomies high epidural anaesthesia is necessary. This is done with the patient in the exaggerated Trendelenburg position and through the use of large doses (50 to 70 c.cm.) of 1½ per cent. solution of novocain. With this technique the anaesthesia will include the lower thoracic segments. High sacral anaesthesia, which has been used largely in gynaecology (König, Schlimpert, Schneider, Kehrer, etc.), is not reliable, and is also dangerous; Schweitzer has collected 10 fatalities in 3,450 cases. On this account it will hardly be accepted as the method of choice. Fidel uses epidural anaesthesia even in stomach resections. He injects 25 c.cm. of 2 per cent. novocain solution below the eighth spinal process, just beneath the ligamentum flavum, which is just punctured by the needle. A complete anaesthesia results in fifteen minutes, and lasts for from one to one

and a half hours. Although surgery in the true pelvis can be satisfactorily done with deep epidural anaesthesia, it is far better to use the less dangerous parasacral method.

#### 6. Spinal Anaesthesia.

With spinal anaesthesia both the rami communicantes and the spinal nerves are blocked. It results in a complete anaesthesia, which includes the abdominal wall. With the patient in the proper position, the anaesthetized field can be made to include the sixth dorsal segment, so that surgery in the upper abdomen is painless. This method is recommended by many surgeons, who emphasize its safety (v. Bloch, Ceccarelli, Chalié, Chaurin, and Moya, Labe, Lane, Morrison, Vaquié, etc.). Morrison states that he uses spinal anaesthesia in 97 per cent. of all his surgery, and always for laparotomies. In the last ten years he has a total of 11,000 cases without fatality. On the other hand, many authors caution against the use of spinal anaesthesia in surgery of the upper abdomen. Fatalities are reported by Chevassu, Featherstone, Hewer, and others. In the last ten years I have not used spinal anaesthesia because of its dangers and disadvantages, but before 1914 I used it only in very exceptional cases. Spinal anaesthesia is recommended by Farr, Skillern, and Southam for emergency surgery—for example, intestinal obstruction and peritonitis—but it is dangerous, because it tends to decrease an already low blood pressure. This further decrease can lead to collapse. In such cases at least pituitrin, which is recommended by Hagedorn for every spinal anaesthesia to diminish the drop in blood pressure, should be given. I consider local anaesthesia of the abdominal wall and mesenteric anaesthesia combined with a little ether, or in cases of stomach resection splanchnic anaesthesia, preferable to spinal anaesthesia.

#### INDICATIONS.

Crile's teachings of anoci-association should be followed in all abdominal surgery; even when operating with general narcosis the sensory nerves should be blocked to decrease the amount of narcotic used and also the shock. With simple operations such as appendectomy an equally good result can be obtained with local anaesthesia as with nitrous oxide or narcylen. But in major operations, particularly in gastrectomy, intestinal resections, or cholecystectomy, the advantages of combined anaesthesia are so marked that it should be used in every case. It may be advisable to use general narcosis at first with extremely nervous young patients to produce temporary unconsciousness while anaesthetizing the abdominal wall and splanchnics. In many cases with complete painlessness a further narcosis is unnecessary, and in all cases the greatest amount of the narcotizing agent is spared. Despite the fact that local anaesthesia is not only difficult but unsatisfactory in very stout patients, it should be used as much as possible, because with combined anaesthesia the amount of narcotic used is diminished, which is of great importance as these patients have fatty hearts.

With old people it is a great advantage to avoid every ether narcosis, as these patients almost always have some chronic respiratory disorder. A combined anaesthesia of nitrous oxide or narcylen may be used with these older patients. Where a deep or long narcosis is contraindicated because of heart trouble, lung disorders, or advanced cachexia, the operation can be done with success under local anaesthesia, thus eliminating operative contraindications. In no case have I as yet refused to operate, and despite the liberal indications have not impaired my total results. I have successfully done large resections under regional anaesthesia on patients who, because of their poor general condition, were refused the smallest operation by surgeons who always use general narcosis. It is significant that my abdominal surgery in very old patients has given almost as good results as in the young. There are 455 patients between 60 and 88 years of age in 3,315 laparotomies. Of these there were 55 post-operative deaths; but as a rule these were hopeless cases from the start, being moribund from gangrene of the entire small intestine, or advanced peritonitis from perforated gall bladder or colon, etc. Beyond this the mortality of the old is not much greater than that of the young. But in these cases it is

specially important to prevent as far as possible pneumonia by very careful after-treatment (regular deep breathing, free expectoration, helped by the use of camphor, etc.).

#### OPERATIVE RESULTS.

The fact that patients can be successfully operated on under local anaesthesia in cases in which surgeons have declared it impossible under general narcosis was stated by Gottstein, a pupil of Mikulicz, thirty years ago. The fatalities due to the so-called operative shock which, thirteen years ago, I asserted should be regarded as late anaesthetic deaths, can be decreased either by local or combined anaesthesia, providing haemostasis is exact and little blood is lost during the operation.

Fatalities from lung complications following operations under regional anaesthesia are seldom seen. Pneumonia does occasionally occur in patients with chronic bronchitis who have had operations in the upper abdomen. But the prognosis depends upon the functional capacity of the heart, which is not injured as would be the case with general narcosis. In addition, the diagnosis of pneumonia is made too frequently after laparotomy because the mere presence of râles is used as a basis for this diagnosis. Wheeler has shown that the râles are secondary to acute oedema of the lungs resulting from fixation of the diaphragm, which is a protective measure against pain. I have not had a single fatality from pneumonia in 841 stomach resections for ulcer, 185 intestinal resections, and 259 cholecystectomies. There were 7 pneumonia fatalities in 264 stomach resections for cancer, 4 of which were secondary to combined anaesthesia and 3 occurred after local anaesthesia. It is of significance that in my material there is practically a complete absence of fatalities secondary to acute stomach or intestinal paralysis. Thus there remain those fatalities which result from insufficient asepsis before or during the operation and which naturally terminate fatally both in old and young patients.

Some examples of how the results of the operation may be improved by systematic use of regional anaesthesia may be introduced here. As my work is confined exclusively to private hospitals, in the last ten years I have performed almost every operation under local or combined anaesthesia, as patients objecting to local anaesthesia are not admitted.

The results in gastric resection for ulcer are markedly improved, as no fatalities due to pneumonia and stomach or intestinal paralysis occurred, although in the last ten years I have practically always done a resection even with old people and patients in a risky state for operation. In 841 resections there were 45 fatalities = 5.3 per cent. mortality. Moreover, the rate of mortality in operations for acute gastric haemorrhage was very high (54 resections with 8 deaths), the highest being in cases where the operation was performed several days after the commencement of the acute bleeding (23 resections with 7 deaths), whilst in early operation—that is, twenty-four to forty-eight hours after the onset of acute haemorrhage—the results are much better (26 resections with 1 death). In all other resections for ulcer I have had a mortality of 4.7 per cent. During the war the mortality was unusually high (81 resections with 11 fatalities = 13.5 per cent. mortality), this being due to poor asepsis. Since 1919 it has gone back to 2.7 per cent. in resections for gastric ulcer, and in resections for duodenal ulcer from 8.1 to 2 per cent. The results are also good in radical operations for gastro-jejunal ulcer, in which not only the greater part of the stomach but also the anastomosing loop of the bowel is resected, there being 4 deaths in 68 cases, or a mortality of 5.9 per cent. I wish to emphasize that in my 841 resections for ulcer there were no fatalities from pneumonia although 87 patients were 60 to 78 years of age. This refutes the teachings of Gottstein, who asserted that the danger of lung complications is not diminished with local anaesthesia in comparison with general narcosis.

In radical operations for cancer of the stomach the mortality depends upon the extent of the resection. It is greatest in cases where the cancer has invaded the neighbouring organs, necessitating the resection of part of the pancreas, liver, transverse colon, etc., there being 44 fatalities in 109 resections (41.7 per cent.); whereas in 155 resections of the stomach alone there were 11 fatalities

(7.1 per cent.). The importance of the anaesthesia is seen by the fact that in cases of advanced cachexia the resection can still be successfully performed; even in 13 cases where the patients weighed less than 80 lb. before the operation, they all recovered. On this account a two-stage resection of cancer is unnecessary.

Fatalities within forty-eight hours after the operation are very rare. Even with my extended indication for resection (435 cancer operations, 264 resections, 7 complete gastrectomies, 75 gastro-enterostomies, and 89 exploratory laparotomies) I had only one death within forty-eight hours after the operation—in a man aged 73 years who had undergone subtotal resection of the stomach.

The results of resection in old patients are not really worse than among the younger; for in the 88 patients over 60 years of age there was a mortality of 22.4 per cent., as contrasted with 20.8 per cent. in all the resections. In 52 cases of uncomplicated stomach resections the mortality was 9.6 per cent., while in 36 cases complicated with liver and pancreatic resection it was 41.7 per cent.

My results in a small series of gall-bladder operations also show the satisfactory effect of the anaesthesia, in so far that fatalities from operative shock and liver insufficiency as well as from pneumonia are absent, and also that the results are satisfactory in old patients.

There were 5 fatalities in 216 cholecystectomies, of which 2 were due to lung emboli, 2 to peritonitis, and one to post-operative haemorrhage in a case of Basedow's disease which also had an associated gastro-enterostomy. The mortality is therefore 2.3 per cent. In 43 cases of cholecystectomy and choledochotomy for obstruction due to stone there were 4 fatalities. These were: a woman, aged 65, who died four weeks after operation from a subphrenic abscess; an emaciated patient (poor food after the war), aged 35, who died from a haemorrhagic diathesis (haemothorax and haemo-pericardium); and two deaths from peritonitis. In 20 old patients (aged 60 to 77 years) there was only one death, despite the fact that three had had common duct obstruction for six months.

In 143 cases of resection of the small intestine there were 87 cases of resection of stomach and intestine for unhealed ulcer following gastro-enterostomy or gastro-jejunal ulcer which will not be considered in this series. As in the 56 remaining cases the resections were necessitated by necrosis of the intestinal wall, the prognosis depended first upon the presence of peritonitis at the time of operation. There were 8 post-operative deaths: of these, 5 were due to peritonitis and gangrene, and one to haemorrhage into the adrenal; one was a woman, aged 76, who died one day after resection of 4 metres of strangulated gangrenous bowel; one was a man, aged 62, who died twenty-four hours after resection of 2½ metres of gangrenous jejunum caused by thrombosis of the superior mesenteric vein; death was probably due to thrombosis of the vena porta, which may have been present at the time of operation. Despite the fact that 19 patients were over 60 years of age, there was no fatality from pneumonia. Out of 9 patients who were between 71 and 81 there was only one fatality—that of the 76-year-old woman already mentioned.

In colon resections the results have been markedly improved; this is due to the fact that among my cases not only have there been no deaths from pneumonia, but also that post-operative intestinal atony, which endangers the suture, has not been observed; and again, that with local anaesthesia the operator has ample time to make an exact intestinal suture in three layers, so that with lateral anastomosis no leakage need be feared. It is important that the bowel be empty in one-stage resection. There were 17 fatalities, or 13.1 per cent. mortality, in my 129 cases. In cancer resections the mortality is 23.6 per cent. (55 operations with 13 deaths). In the two-stage resections the mortality was higher (16 operations with 6 deaths), because, in consequence of the invasion of the adjacent organs in 6 cases, beside the colon resection it was necessary to do an extensive resection of the small intestine, in one case nephrectomy, and in one case splenectomy. In the one-stage resection of the caecum and colon ascendens the mortality is high (20 cases with 5 fatalities), because formerly the one-stage operation was done also for

acute obstruction. In the one-stage resection for cancer of the descending and sigmoid colon the mortality is lower (19 cases with 2 deaths). One patient, operated on during the war, died from peritonitis without insufficiency of the suture line, and the other was a patient aged 68, who died two weeks after operation from a recurring heart insufficiency, from an attack of which he had suffered three months previously. It is of further interest that there were 11 patients in this series who were 60 to 75 years of age with only the one above mentioned death.

#### CONCLUSION.

In major abdominal operations general narcosis with ether or chloroform injures the parenchymatous organs on account of its longer duration. This may lead to death through insufficiency of the organ.

These injuries to the organs may be avoided by the use of combined anaesthesia; therefore it should be employed in every greater laparotomy in which it is impossible to perform the whole operation under regional anaesthesia. In combined anaesthesia nitrous oxide or narcoylen is the least injurious.

Mesenteric anaesthesia is almost harmless and may be resorted to in every case. It is the most effective agent in the combined anaesthesia.

Paravertebral anaesthesia should be used only in operations in which the injection on one side is sufficient.

Splanchnic anaesthesia after the method of Braun is almost without danger, and in about 80 per cent. of operations on the upper abdomen sufficient.

Parasacral anaesthesia, combined with blocking of the lumbar segment, is sufficient for radical operation for cancer of the rectum and for all gynaecological operations.

By the use of regional or combined anaesthesia the results of major abdominal operations are improved, because death from so-called operative shock, pneumonia, and atony of the bowel can be almost always avoided.

## II.—CHARLES W. MOOTS, M.D., F.A.S.C., Toledo, Ohio, U.S.A.

### EVALUATION OF RISK, BLOOD PRESSURE PROTECTION, AND NITROUS OXIDE-OXYGEN ANAESTHESIA AS VITAL FACTORS IN SAFER GASTRIC SURGERY.

SAFER gastric surgery with precise methods of risk evaluation to the patient has in forty-six years reduced the operative mortality from 56 to 4.6 per cent. for the year 1925, as reported by several of our leading surgical centres. To appreciate the factors entering into this improvement, and to approach more nearly the Utopian dream of no morbidity and 100 per cent. cures, I beg of you to bear with me in their consideration as follows: (1) The evaluation of the patient's resistive strength, or the potentiality of each individual case. (2) Blood pressure protection. (3) Nitrous oxide-oxygen anaesthesia.

The mensuration of potentiality in gastric surgery offers a nicety that is found in no other field. While this class of patient is coming to surgery considerably earlier in their disease than formerly, yet there exists an astonishingly high percentage that have been treated for years with no more definite diagnosis than "dyspepsia" or "indigestion." This, of course, leads to a great loss in nutrition, which must necessarily affect the physiology of all important organs, particularly the blood chemistry. Whether the pathology present is that of an ulcer or whether it be malignancy, one is apt to be dealing with a patient who has been ill for a very long time, and is therefore far below par in many respects. Unusual care is needed to bring him safely through the operation and assure him of the least further disturbances to his alimentary tract.

In estimating the risk it is customary in most clinics during the last decade to carry out certain routine investigations that are thought by all to be a necessity. Among these might be mentioned a most careful clinical investigation, with stress upon history-taking, to be followed by laboratory aids, such as chemical, bacteriological, physiological, roentgenological, electro-cardiographs, and others. These are all exceedingly important, and are to be encouraged. However, may I here interject the thought that our graduates in medicine may become so accustomed to relying upon laboratory and technical apparatus that they may fail to develop the faculty to draw reasonably proper conclusions from the history and general clinical picture; at least, is it not reasonable to give the clinical picture a bit of thought before writing orders for the use of every appliance in the hospital? Fearing, however, that I may be misunderstood, let me insist that we bring to every case every known aid for determining the exact condition present; for it is certainly possible by so doing to change many cases of extremely bad risks to at least fair risks. Many cases needing gastric surgery will have been vomiting, probably for some time, resulting in a great lack of fluids, and probably a profound acidosis, due to a lack of nourish-

ment. It is also possible to have the opposite condition, alkalosis, and this is especially true if the patient has had persistent emesis with loss of hydrochloric acid, or has been treated by means of large doses of sodium bicarbonate. These conditions are easily determined by finding the carbon dioxide combining power of the blood plasma, and a urinalysis. The determination of chlorides in the blood is highly important, for while we may not know what becomes of them we do know that they are a necessity in combating the toxæmia so often present in the obstructive type of cases. Being aware of such conditions, we are forewarned and forearmed, and the treatment is easy and reasonably certain in its effects. Most certainly the blood must receive much further study, demanding at least the tests for lues, sugar, red and white cell count, and haemoglobin. More and more we feel the grave importance of a full knowledge of the character of the spinal fluid. We believe the liver and kidney functions to be exceedingly important in surgical cases, and no effort to measure these should be neglected. We are rapidly gaining confidence in skilful interpretation of roentgenograms of the chest as useful aids in determining the condition of the lungs, heart, and larger vessels. The psychology of the patient has been too long neglected, and we may do well to seek his co-operation in all our efforts. It is probably true that the function of all important organs is markedly influenced by the psychical attitude of the patient.

Many years ago—twenty to be exact—long before the general and special laboratories were giving the aid that we find to-day, we were confronted by the fact that we had no standardized tests for measuring the risk confronting us. An incomplete urinalysis and hasty examination of the heart and lungs comprised the usual investigations. It was at this time that in America the question of blood pressure was attracting attention among our leaders. True, one heard of only one pressure, the systolic. We soon found that this information fell far short of giving us the necessary guidance for formulating a rule. It probably does represent the total labour that is being expended by the arterial system at a given time. It is affected by many factors, including even psychical disturbances—as anger and fear, for example.

With the inestimable aid of my anaesthetist, Dr. McKesson, we then commenced a systematic study of the whole question of blood pressure, keeping records of our findings previous to, during, and subsequent to operations. We had little aid in this work from the literature, as Janeway's book, which was published in 1907, advocated the observance of only the systolic pressure in guiding surgeons. It was the first formidable treatise on the subject of blood pressure we found. Every case operated on furnished us with interesting data. These results finally gave us the necessary information to enable us to formulate an index for operability. In this work we received valuable aid from Dr. W. J. Stone, who was then medical chief of Flower Hospital, where most of our investigations were made. In order to express this index in percentage we coined the term "pressure ratio." This is obtained by dividing the pulse pressure by the diastolic pressure, thus:

$$\frac{\text{Pulse pressure}}{\text{Diastolic pressure}} = \frac{\text{Pressure ratio per cent., or}}{\text{Index for operability.}}$$

$$\frac{40 \text{ P.P.}}{80 \text{ D.P.}} = 50 \text{ per cent. normal.} \quad \frac{20 \text{ P.P.}}{80 \text{ D.P.}} = 25 \text{ per cent. inoperable.}$$

Rule.—If the pressure ratio is high or low there is reason to apprehend danger. If it lies between 30 and 70 per cent. the case is probably operable; if below 25 per cent. or above 75 per cent. it is probably inoperable.

In applying the rule during the operation it gave us early warning of shock, and enabled us either to apply remedial treatment or to bring the operation to a close. Finally, after eight years of testing this rule, I read our results and conclusions at the twenty-ninth annual meeting of the American Association of Obstetricians and Gynecologists in 1916, in a paper entitled "Observations on blood pressures during operations." The rule has been checked by numerous leading anaesthetists in America on many thousand cases, notably by Dr. Miller of Providence and Drs. Ruth and Tyler of Philadelphia, reporting their conclusions in two papers. As our continued use of this rule

has only added to our then acquired confidence, I take the liberty of repeating the conclusions given in 1916.

1. The systolic pressure alone is of very slight, if any, value.
2. The diastolic pressure alone is of much more value than the systolic alone.
3. The pressure ratio is the essential factor, and offers the earliest danger signal.
4. There are certain elements in technique which have marked and constant effect upon the pressures. These are as follows:
  - (a) The psychical or emotional state of the patient.
  - (b) The position of the patient upon the table, the extreme Trendelenburg being the worst.
  - (c) Overdosing by the anaesthetist.
  - (d) The amount of traumatism inflicted by the actual operation, such as cutting and tearing the tissues with the hands, scissors, or other dull instruments; the packing of large gauze packs instead of rubber tissue into the abdominal cavity.
  - (e) The preservation of the fluids in the body up to the hour of the operation, this being absolutely necessary to maintain the usual pressure.

In an article appearing in the *Canadian Medical Association Journal* during 1925 the author, Dr. F. H. McMechan, very kindly refers to our work, and very properly makes the following additional statement:

"However, what happens during an operation may invalidate any assurance of safety first under Moots's index of operability, and for this reason the Anaesthesia Research Society insists upon five-minute blood pressure guides and protection during the entire period, and has established certain degrees of circulatory depression for the information of the surgical team. These, as first formulated by McKesson and then adopted by the committee of the National Anaesthesia Society, are:

- "(1) *Safe*.—Fifteen per cent. increase in pulse rate without increase in blood pressure; or 10 per cent. decrease in blood pressures without a decrease in pulse rate.
- "(2) *Dangerous*.—Twenty-five per cent. increase in pulse rate, plus 10 to 25 per cent. decrease in blood pressures.
- "(3) *Shock*.—A pulse rate of 100 and rising with progressively falling blood pressures reaching a systolic of 80 mm. or less. If shock continues for thirty minutes or more during operation, without effective remedial measures, death is almost inevitable in twenty-four to seventy-two hours. This guide discloses the onset of shock at least twenty minutes earlier than it is indicated in any other way."

During the past year we have, at the Lucas County Hospital, added another test, known as the "Energy Index." This is the sum of the systolic and diastolic pressures multiplied by the pulse rate. The numerals of thousands only are used. Thus:

$$\begin{array}{rcl} \text{Systolic plus Diastolic times pulse rate} & = & \text{Energy index.} \\ 120 \quad \quad \quad 80 \quad \quad \quad 72 & = & 14,500 \text{ mm.} \end{array}$$

This result would be read as "fourteen." Cases with this index at 12 to 18 would be considered safely operable.

While this test seems to coincide with our own rule, we have used it but a short time, and will require experience with it before making a positive statement as to its utility. May I add at this time that the determination of our own rule and that of the energy index rule, at the completion of the operation renders a most useful guide to post-operative convalescence or for subsequent therapy?

Now as to the question of the relationship of nitrous oxide-oxygen anaesthesia to our general subject, let it be fully understood that I do not urge this agent to the exclusion of all others. Rather, I would advocate *professional anaesthesia* as the most important factor, in that this will ensure continued professional research, which will bring the largest measure of safety to the patient.

There is considerable discussion at this time as to the nature of the action of the different agents used in causing narcosis. Personally, we have held to the idea that the chemical reactions which favour nitrous oxide anaesthesia are, briefly, as follows:

It procures anaesthesia by reason of its interference with the use of oxygen by the brain cells, apparently exerting no other influence except this oxygen interference; furthermore, its total effect on the body continues but a few minutes beyond the termination of its administration. In fact, the dangers and difficulties of nitrous oxide administration are practically all technical and therefore controllable.

Ether, on the other hand, probably produces anaesthesia by dissolving the lipoids of the brain; in addition, it also dissolves the lipoids in many other exceedingly important structures, such as the lecithin in the red corpuscles, the fats in the kidneys, the liver, and even the lipoids in the

phagocytes. Its difficulties, therefore, come from a chemical source, often delayed, and apt to be uncontrollable.

In 1907 Dr. McKesson and I became interested in nitrous oxide-oxygen in a small way. At first our difficulties were many, ignorance of the necessity of joint study and co-operation, poorly devised equipment for administration, and a lack of experience in the signs of this form of anaesthesia being the causes, in the light of our present knowledge.

It is true that for two or three years we had some of the troubles commonly attributed to gas anaesthesia, but we felt that as the apparatus was improved and our experience broadened, these difficulties might be overcome and we could offer our patients some decided advantages. Our great difficulty was due to less relaxation than we had secured under ether, and the necessity of adding ether to the gases too frequently. This problem was not solved in a month, or even a year; but, instead of condemning the principle, we intensified our investigations. Finally, we found that by sympathetic co-operation it was quite possible to perform any major operation under this form of anaesthesia, with very few unpleasant experiences on the part of the patient. There being no unpleasant odours, the period of inception of narcosis being very brief and tranquil, post-operative nausea averaging 4 per cent., all have much to do in removing the dread of surgery, and add much to the brevity of morbidity, and it especially to be sought in gastro surgery where nutrition is greatly needed. To-day we are happy in the conscious enjoyment of a technique which leaves little to be desired.

To obtain the benefits of such a technique, which includes complete muscular relaxation without added danger, requires the combination of skill and hearty co-operation between surgeon and anaesthetist, as well as of all who have to do with the pre-operative preparation of the patient, which preparation should be of the nature to prevent as many adverse stimuli as possible from entering the patient's nervous system. While haste is to be condemned, yet when an operation has been decided upon it should be done without unnecessary delay. This minimizes adverse stimuli coming from well meaning but uninformed friends. Officials and nurses about the hospital must understand the importance of proper psychological suggestions. Complete rest during the night preceding the operation is secured by whatever sedative is considered best for the individual case. We always use some preliminary narcotic, except in the cases at the two extremes of life—the very young and the aged. In the latter, we do not hesitate to use morphine alone, believing that it is the best single agent for preventing shock during and following operative procedures.

For the average sized adult patient our usual dose is morphine sulphate 1/6 grain with scopolamine 1/200 grain, given hypodermically two hours before the operation; this is repeated one hour before operation; the dosage is varied according to the age, size, and psychical state of the patient as well as the type of operation to be done. All visitors, including relatives, are excluded from the patient during these two hours. By these means the patient reaches the operating room practically asleep, at least with absolutely no fear, and therefore with an exceedingly high threshold to external as well as internal stimuli.

The operation started, we believe that it should be completed in the briefest possible space of time compatible with the best work. Our blood pressure records show that time is a factor not to be ignored. They also give us convincing evidence of the depressing effect of rough handling of the abdominal viscera and tight packing with gauze. One of the great blessings of nitrous oxide anaesthesia is that it fosters the same gentle touch by the surgeon that is necessary in the use of local anaesthesia. This is a very distinct gain for the patient. All of these points affect not only the mortality, but the morbidity as well. We are realizing more and more that it should be our aim not only to save life, and to cure the disease, if possible, but to return the patient to his position in society in the briefest possible time, subjecting him in the meanwhile to the least possible danger and discomfort. We feel that expert professional nitrous oxide anaesthesia.

when used in connexion with gentle and skilful surgery offers just those things to the patient.

In closing, I wish to offer these few following conclusions, which Dr. McKesson and myself both feel, have been proved during twenty years of more or less constant team work:

1. Nitrous oxide-oxygen as an anaesthetic, although difficult of administration, is by far the safest anaesthetic in skilled hands.

2. It produces anaesthesia without appreciably injuring any cells in the body, in a pleasant manner, in a brief time, and without, except in rare instances, the much-dreaded debilitating nauseous experiences which are the rule with ether.

3. Notwithstanding many published statements to the contrary, it may be successfully used in all abdominal surgery, and is especially indicated in cases requiring great length of time.

4. It favours the production of the very best psychical condition of the patient, and therefore predisposes to a higher percentage of permanent cures, with shorter periods of morbidity.

5. It favours the growth of more skilful anaesthesia, which is greatly to be desired.

6. While the degree of M.D. carries with it the legal right to administer anaesthetics, there is a moral responsibility which requires special training for this work.

7. The surgeon must realize constantly that he is dealing with a living organism and not a mere mechanical device, and that rough traumatic attack will be followed by depression and shock in many cases.

### III.—Dr. T. BRANDT,

Bergen.

#### ACETYLENE-OXYGEN ANAESTHESIA IN GASTRIC SURGERY.

DURING examinations regarding the effect of nitrous oxide gas, H. Wieland thought of trying a gas which in pharmacological respects acted like nitrous oxide gas, but which at the same time was more soluble in the blood—namely, acetylene. Thereby he hoped to be able to simplify the narcotic apparatus considerably, and also to provide a means that possessed all the advantages of nitrous oxide gas anaesthesia. Together with C. J. Gauss, the Würzburger gynaecologist, he prepared an acetylene narcotic, and this seems now to have triumphed throughout Germany.

Chemically pure acetylene is employed for the narcosis. It possesses a faint smoky smell and a slightly sour taste; thus in no way does it resemble the "acetylene odour" we are acquainted with from carbide lamps. It has been placed on the market under the name of "narcylen," in large (1.6 metres high) steel cylinders; such a cylinder is sufficient for twenty hours' narcosis. The gas is produced from calcium carbide, but is thoroughly cleansed of all impurities, including  $H_2S$  and the extremely poisonous phosphoric hydrogen. Possibility of explosion of the cylinder has been quite eliminated by a patent arrangement. During the narcosis oxygen must also be administered from an ordinary oxygen cylinder. The mixing and dosing of the gases take place through a narcotic apparatus, which has been constructed by the firm of Draeger, and somewhat resembles that firm's apparatus for ether and chloroform anaesthesia.

From the oxygen containers and the "narcylen" cylinder the gases are directed to their respective manometers, which show the quantity of gas in the container. The acetylene passes first through two purifying bottles of ordinary water—in order to remove the acetone—before mixing with the oxygen in the "gas mixer," thence it is led into a large balloon, which serves as a reservoir. The gas mixture is administered to the patient through a strong tube, and a special narcotic mask made of rubber which can be easily adapted to fit the patient's face. The mask has a ventilating apparatus similar to Sudeck's ether mask, and allows the respiratory air to pass in one direction only. One half of the apparatus is arranged like Roth-Draeger's, so that it is also possible to administer an ordinary anaesthetic, or a mixture of ether and acetylene. The whole

mechanism has a somewhat complicated appearance when seen for the first time, but it is easily learnt, and acts well.

The administration of the anaesthetic is very simple. The apparatus is first examined to see that it works properly. The mask is then applied very carefully, as it must fit tightly round the face. The mask covers the nose, mouth, and parts nearest to these, but not the eyes, in order that the corneal and pupillary reflexes may be observed. When employed for long narcosis it is generally fixed round the head with a strap arrangement. When placing the mask in position a little oxygen is given; if all is then in order, the gas mixture is administered—70 per cent. acetylene and 30 per cent. oxygen. It has been proved that such a mixture is the most suitable when introducing the narcotic. The correct proportion of the gases is read in percentages from their respective manometers.

Most people find the smell of "narcylen" almost pleasant, and it is a rare occurrence for patients to be unable to breathe freely on account of the smell, as is often seen with ether or chloroform anaesthesia.

The patient becomes unconscious quickly, in practically all cases after one, or at most two, minutes. If it takes longer than this, it may almost always be attributed to the fact that the mask does not fit properly. In certain cases there is slight excitement, but nothing compared with what is seen in chloroform, ether, or ethyl chloride. As a rule it is quite absent. It is possible to commence operating one or two minutes after administration of the narcotic; but if really perfect relaxation of the muscles is desired it is advisable to wait five minutes.

When the patient is under the anaesthetic the quantity of acetylene is reduced (5 per cent. for every five minutes) in order to find the concentration that produces the most effective relaxation of the muscles and deep narcosis respectively. Then it is desirable to remain at this proportion. As a matter of fact, experience has proved that the patient can be kept under the anaesthetic for hours with 20 to 30 per cent., and that with 40 to 50 per cent. there is generally less tension of the muscles than with a greater concentration.

If the patient has partaken of food immediately before, it may happen that he will vomit, but vomiting or retching scarcely ever takes place if the anaesthetic is given on an empty stomach.

When it is desired to finish, the mask is removed, and if a low percentage of acetylene has been employed the patient awakens practically momentarily. In the case of more concentrated mixtures, perhaps two, but seldom more than five, minutes elapse before the patient regains consciousness. Excitement is even rarer than during induction. In the majority of cases the patient feels quite well afterwards. Headache and sickness are seldom met with, and by no means as frequently as after chloroform or ether narcosis.

When under the anaesthetic the face becomes slightly flushed. Cyanosis is rare, but it may, of course, appear here as in any other anaesthetic when the tongue falls back and the passage to the windpipe is obstructed, or when an insufficiency of oxygen is administered. The cyanosis encountered when in very profound ether or chloroform narcosis, which is attributable to poor ventilation of the blood on account of respiratory paralysis setting in, does not occur during acetylene narcosis. The reason for this is that acetylene is a very weak anaesthetic, which even in the greatest concentrations is not capable of paralysing the respiratory centre. Overdose is therefore an impossibility.

The anaesthetic does not appear to have any effect on the function of the heart, although the blood pressure—as is the case in nitrous oxide gas anaesthesia—rises quite considerably, and can increase up to 20 to 40 or even 50 mm. of mercury. The cause of this is not known. The pulse remains unchanged. Acetylene does not appear to have any effect on the liver or kidneys either. It is possible, therefore, to anaesthetize the same patient several times without fear of symptoms of intoxication, such as occur in the repeated use of ether or chloroform.

Acetylene anaesthesia reminds us very much of nitrous oxide gas anaesthesia, and from the experience gained it

seems to possess all its advantages, but also some of its disadvantages.

Let us look at its advantages. It must first and foremost be mentioned that it is harmless. A decided opinion can, of course, only be arrived at after some years of experience; but no case of death has up to the present been reported. It is undoubtedly a very pleasant form of anaesthetic for the patient. As far as the anaesthetist is concerned, a great advantage is that unconsciousness sets in rapidly and without any excitement, and also that recovery takes place, so to speak, immediately after removal of the mask. Another great advantage is that it is practically free from after-effects in the form of sickness or vomiting. Moreover, it is so simple to administer that it can be entrusted to less experienced anaesthetists, as overdosing with resultant respiratory paralysis is not possible.

But it has its drawbacks also. It requires a complicated and expensive apparatus. "Narcylen" and the oxygen cylinder are not cheap either, so that the anaesthetic, apart from the apparatus, is three or four times as costly as ordinary ether. Merely on account of the expense, therefore, it will be difficult for it to compete with ether or chloroform, if experience should not prove that its advantages—especially its harmless nature—are considerably greater than we are at present aware of.

As we all know, acetylene gas is very inflammable, and the acetylene-oxygen mixture highly explosive. It might therefore be thought that with this anaesthetic it would be impossible to make use of a naked flame in the operating room (boiling of instruments, thermo-cauterization); such is not the case, however. As is also the case with ether, a certain risk is always present, and especially in abdominal and gynaecological operations, where we often have recourse to thermo-cauterization, this proves a disadvantage. To be on the safe side, certain operators never make use of it in operations where they think they may have to cauterize. An accident in Munich showed that this is no exaggerated precautionary measure.

The greatest drawback is, however, that pure acetylene is not always sufficiently powerful, even though it be quite sufficient for most surgical operations. In laparotomy, where, of course, a deep narcosis is often required, the continuance of muscular rigidity may give rise to some anxiety, and it has happened that surgeons have had to resort to ether or chloroform during the operation. If a scopolamine-morphine injection (0.0003/0.015 g.—0.02 g.) has been administered beforehand—as recommended by Wieland and Gauss—then we may certainly depend on satisfactory muscular relaxation; but, on the other hand, we have no longer a purely acetylene narcotic: it becomes now to a great extent a mixed one. As previously mentioned, the apparatus is so arranged that it is possible to administer to the patient an ether-acetylene mixture when the narcosis is not profound enough, but experience seems to show that this mixture is not a particularly good one. Others, again, recommend it.

Some operators assert that acetylene anaesthesia causes increased capillary bleeding; in certain cases it is said to have been very troublesome. Several operators have, however, not noticed this, and personally I am of the opinion that capillary bleeding is no more intense than with ordinary ether anaesthesia. Again, as previously mentioned, the blood pressure rises quite considerably, and the acetylene narcotic ought, therefore (as is the case with nitrous oxide gas), to be contraindicated in patients with hypertonia. This is, so far as is known, the only contraindication. It has, as a matter of fact, been made use of in several instances of haemorrhagic diathesis, in badly compensated defects of the heart, in pulmonary tuberculosis, and chronic bronchitis, without noticing any unpleasantness from its use; but for the present, having regard to the capillary bleeding, we ought also to regard the haemorrhagic diathesis as a contraindication.

If I may—on the basis of the experience obtained up to the present—give my opinion briefly about the anaesthetic, it would be as follows.

"Narcylen" anaesthetic is a clinical anaesthetic, excellent for all surgical work where a very profound narcosis is not required. It is also well suited for laparotomies, but only in conjunction with a previous scopolamine-

morphine injection. On account of its simple administration, the rapidity of the narcosis, the rapid coming to, and the inconsiderable after-effects, it seems to be most suited for use in surgical polyclinics. It is also a form of narcotic that deserves the physician's full attention, and quite surely has a future before it, even if it will never quite take the place of ether or chloroform.

The narcotic apparatus has been improved of late. I have, however, no personal knowledge of the new pattern. In it the expired air is conducted back to the apparatus again, where it is purged of the carbonic acid by passing through sodium hydrate. The acetylene passes through the caustic soda unchanged, and is collected in the gas reservoir; thus it circulates in an enclosed circuit. In this way the anaesthetic has become considerably cheaper; so cheap, in fact, that, as regards price, it can compete with ether; at the same time fear of explosion has been reduced to a minimum, as the acetylene gas no longer escapes into the operating room. Those who make use of the new apparatus state that the anaesthesia is as satisfactory as with the older pattern.

#### IV.—C. LANGTON HEWER, M.B., B.S. LOND.,

Anaesthetist and Demonstrator of Anaesthetics at the Medical College, St. Bartholomew's Hospital.

#### ENDOTRACHEAL NITROUS OXIDE-OXYGEN-ETHER ANAESTHESIA IN GASTRIC SURGERY.

It will be admitted by all that gastric surgery makes large demands upon the anaesthetist. In the first place, the incision is made in that part of the abdomen in which respiratory movement is at its maximum, so that it is essential that anaesthesia should produce as small a respiratory excursion as possible. Secondly, in order to obtain the best exposure, the recti and other abdominal muscles must be completely relaxed. This desirable result may be difficult to attain owing to the fact that severe traction upon the peritoneum and diaphragmatic attachments may result in reflex laryngeal spasm. In the third place, operative trauma in the upper abdomen gives rise to more shock than is the case in the lower abdomen and pelvis. Lastly, gastric operations tend to be followed by more pulmonary complications than do those on other parts of the body.

The problem, then, is to provide an anaesthetic which affords (1) minimal respiratory movement; (2) absolute muscular relaxation with no possibility of laryngeal spasm; (3) protection from operative shock; (4) absence of post-operative pulmonary complications.

It will be seen, therefore, that an ordinary inhalation anaesthesia does not fulfil all these conditions. If ether be used, either alone or in combination with nitrous oxide and oxygen, the respiratory movements will be comparatively large, although, as an offset to this, the blood pressure will be somewhat raised, thus tending to counteract the fall due to operative shock. The same remarks apply to acetylene-oxygen and ethylene-oxygen mixtures. Chloroform, on the other hand, while affording shallow breathing, is inadmissible on account of the low blood pressure induced during a prolonged administration. Furthermore, in all the foregoing cases laryngeal spasm is always liable to occur and thus prevent complete muscular relaxation.

Turning next to regional analgesia, it is possible to perform high abdominal operations under a combination of splanchnic and anterior field blocks, or splanchnic and paravertebral blocks. In either case, however, we have to contend with an abnormally low blood pressure and poor relaxation towards the end of a prolonged operation. Both disadvantages can be partly overcome by using a light general anaesthesia as well, but this method demands the closest co-operation between surgeon and anaesthetist. In addition, the time taken in preparing the patient is long (about half an hour), and the technique requires a good deal of practice. I have used this combined method for 25 cases of upper abdominal operations, nearly all of which were partial gastrectomies, but the results, although fairly good, were below those obtained with the technique described below.

We now come to the method which in my opinion gives

the best results of all in gastric surgery; this consists in administering a mixture of nitrous oxide, oxygen, and ether through a tracheal catheter. I have now employed this method as a routine for five years in about 3,500 cases, of which about 1,100 were for upper abdominal operations.

Although endotracheal anaesthesia has been practised for some years, the war brought it into prominence as affording the only satisfactory technique for plastic facial surgery. The anaesthesia obtained was so uniformly excellent that in 1920 I tried the same method for major abdominal surgery, and the results were so encouraging that I have continued it up to the present time.

The apparatus required is not extensive. Any sight-feed gas and oxygen machine can be employed, although it is better to have either a pressure gauge or mercury manometer connected with the exit tube to give an indication of the endotracheal pressure. If all the 'connexions' are rigid, an adjustable safety-valve is also advisable, but in most types of apparatus the corks will blow out of the bottles long before a dangerous pressure is reached.

The technique is as follows. The patient is given a preliminary atropine injection and is fully anaesthetized by any method which the administrator prefers. When the jaw muscles are completely relaxed a direct-vision laryngoscope is passed along the dorsum of the tongue until the epiglottis is seen. This is gently pushed forwards with the curved end of the laryngoscope, and the glottis will then come into view. The end of a tracheal catheter is then smeared with sterile vaseline and slipped between the vocal cords and pushed onwards for another three to four inches. The laryngoscope is then withdrawn, and the proximal end of the catheter connected up to the exit tube of the gas and oxygen machine. Difficulties in passing the catheter are nearly always due to the patient being insufficiently anaesthetized. In this case it may be almost impossible to see the glottis, and even if this is accomplished the cords will probably be in a state of adductor spasm. If a catheter is then forced between them some post-operative laryngitis will almost certainly ensue. Opinions differ as to the best position for the patient's head. I have found that if it be placed just flat and exactly in the middle line little difficulty is usually experienced in finding the glottis. Hyperextension of the head, on the other hand, although favoured by laryngologists, stretches the soft parts and should be avoided. When the catheter is in position, a mixture of 50 per cent. nitrous oxide and 50 per cent. oxygen passing through ether is first employed. This may cause a certain amount of coughing, which soon passes off as the anaesthesia becomes more profound. The amount and proportions of the gases are then regulated until the colour of the mucous membranes is just pink and the manometer shows a pressure of about + 5 mm. Hg on inspiration. In an average case the breathing becomes shallow and regular as in a sleeping patient, but occasionally there is a certain amount of obstruction to the return airway due to a large tongue, in which case an artificial airway should be inserted. Two catheters are, as a rule, quite unnecessary in gastric cases. By increasing the proportion and pressure of oxygen the respiratory movements can be brought down to practically zero, and, indeed, complete apnoea may occur for a considerable time, the oxygen diffusing through the bronchioles and alveoli sufficiently rapidly to oxygenate the blood. This, of course, is of great assistance to the surgeon when performing anastomoses, as the suture line is perfectly still.

In long gastric operations it is always advisable to take blood pressure and pulse records at least every five minutes. This can easily be done by strapping a stethoscope end over the brachial artery in the antecubital fossa just below the cuff of the sphygmomanometer. Systolic and diastolic pressures should both be taken, and, if possible, recorded as a graph. In my opinion the best indication of the patient's general condition is given by observing the tendency of the pulse pressure and pulse rate. By this means ample time is given for antishock methods to be adopted before severe collapse has occurred.

Post-operative pulmonary complications can be minimized in two ways. First, at the end of the anaesthesia the gas-oxygen-ether mixture should be switched off and a mixture of 90 per cent. oxygen and 10 per cent. carbon dioxide from

a separate cylinder substituted. This will cause immediate forced breathing by the stimulation of the respiratory centre by the carbon dioxide. The ether vapour will consequently be rapidly washed out of the lungs, the blood will be fully oxygenated by the 90 per cent. oxygen, and the bases of the lungs will be expanded by the hyperpnoea. Patients can be brought round very rapidly by this de-etherizing process, but in gastric cases it is better to discontinue it after about five minutes. The patient will then relapse into a state of light anaesthesia and will remain free from pain for a considerable time. The second way to avoid respiratory complications is to give small doses of atropine repeatedly for three days after operation—gr. 1/200 hypodermically three times a day is a useful average dose. The only possible objection to this treatment is the antispasmodic action of the drug, which might possibly predispose to paresis of the bowel, but I have never seen any trouble follow from this cause.

Let us now consider how the four requirements mentioned at the beginning of this paper are met by the endotracheal nitrous oxide-oxygen-ether technique.

1. Minimal respiratory movement. It will be admitted by most that this method affords less respiratory excursion than any other form of general anaesthesia. It is, in fact, the only way in which we can produce prolonged apnoea with safety.

2. Muscular relaxation. This should be complete. It is obvious that if a catheter is lying between the vocal cords, laryngeal spasm from peritoneal traction cannot occur, and so relaxation should be continuous throughout all stages of the operation.

3. Protection from operative shock. If the suggested practice of recording graphically the systolic and diastolic blood pressures and pulse rate is adopted, the first signs of shock can be detected and treatment instituted without delay. The endotracheal method does not, of course, protect the central nervous system from traumatic stimuli transmitted by the sympathetic system in the same way as does splanchnic block, but I am doubtful whether this is not more than counterbalanced by the continuously low blood pressure involved by the latter method.

4. Absence of pulmonary complications. I have found that if the two suggestions mentioned above are carried out the endotracheal method compares favourably in this respect with any other general, local, or combined technique. It is impossible to eliminate respiratory complications entirely from upper abdominal surgery, as a certain proportion are undoubtedly due more to the operation than to the anaesthetic.

Finally, the best argument in favour of the method which I have endeavoured to describe is that when a surgeon has once operated with it he almost invariably prefers it in future cases.

#### GENERAL DISCUSSION.

Mr. K. W. MONSARRAT (Liverpool) said that in abdominal surgery the surgeon required an anaesthesia which was rapid in induction, gave complete muscular relaxation, did not add to the influences producing shock, and was not followed by pulmonary complications, vomiting, and meteorism. None of the toxic substances by the administration of which general anaesthesia was produced could singly fulfil all these desiderata. No method and no anaesthetic should be considered as routine. Thus, in the case of a powerful, somewhat stout man on whom a gastro-enterostomy was to be performed, gas and oxygen with ether anaesthesia, though valuable in many other cases, was not a good method. In order to get adequate relaxation a proportionately large amount of ether had to be used, and gas, ether, and oxygen anaesthesia, when a considerable quantity of ether had to be used, was very liable to be followed by pulmonary complications. Such a patient had a smoother time if anaesthetized with warmed ether vapour by the Shipway plan. Mr. Monsarrat next remarked on the value of combining the general with a regional anaesthesia; in his own practice a local or regional anaesthesia was always employed. He infiltrated two planes with 0.5 per cent. novocain—the skin and the subperitoneal; this local anaesthesia was the general rule, but in a minority of cases he injected intercostal nerves,

in the subcostal grooves in particular, in operations on the upper abdomen. This local or regional anaesthesia had two advantages—it gave a satisfactory relaxation under a comparatively light general anaesthesia, and it obviated a very definite risk. If a skin incision was made when the patient was but lightly anaesthetized (and unless the surgeon invariably operated in association with one anaesthetist this must occur from time to time) the shock was sometimes definite and a fatal syncope might supervene, particularly in children. He wished to emphasize this risk, and he had had experience of two fatalities. In an operation several years ago, for inguinal hernia on a girl aged 8, ether anaesthesia was used and the patient was reported anaesthetized. When the skin incision was made a movement of the legs occurred, followed by blanching of the face, dilatation of the pupils, and a syncope from which she failed to recover. In the second case the syncope occurred at the end of an operation for acute appendicitis in a girl aged 13; no local anaesthetic was used. When completing the operation Mr. Monsarrat remarked that the anaesthesia was light. As the first stitch was put through the skin there was a kick of the right leg and syncope occurred, the respiration gradually failing. It might be said that such accidents should not happen, but even the experienced anaesthetist would admit that under ether anaesthesia the depth of the anaesthesia was not always easy to estimate. Such accidents were, he believed, eliminated by the use of the local in combination with the general anaesthetic. In gastric and bowel resections he infiltrated the mesenteries, using 0.5 per cent. novocain solution.

Professor Finsterer had referred to the damaging effect of chloroform and ether on the viscera, instancing in particular the liver and kidneys; the influence of ether on pancreatic function appeared to be of still more importance. Dr. R. J. Minnitt, who gave the majority of the anaesthetics in Mr. Monsarrat's operative work, had studied and reported on the incidence of ketosis and acidosis following ether anaesthesia, and had also investigated the effect of ether on sugar tolerance. There appeared to be no doubt at all that ether interfered with pancreatic function. This interference was sometimes transient and sometimes prolonged, and its degree had a direct association with post-anaesthetic vomiting. In insulin they had a specific remedy for this complication. It should be given prophylactically; in ether anaesthesia 10 units were administered immediately the operation was completed, and if vomiting occurred the dose was repeated as often as might be necessary. Mr. Monsarrat did not think it was possible to foresee an unusual degree of susceptibility to ketosis and acidosis. This complication was serious when it occurred in the course of convalescence from an abdominal operation. Happily it appeared to be capable of elimination or control by insulin. Dr. Minnitt's investigations had also shown a parallel relation between blood pressure curves and pancreatic disorganization. Gas and oxygen was generally preferable for the majority of abdominal operation cases, but warmed ether vapour was almost its equal, and, in the robust, was on the whole preferable. In critical cases the surgeon and the anaesthetist should meet before the operation and discuss the method of anaesthesia to be used.

Mr. G. GORDON-TAYLOR (London) said that Professor Finsterer had advanced strong and convincing claims for the use of splanchnic anaesthesia in abdominal surgery. He personally had tried local and splanchnic anaesthesia with light ether anaesthesia throughout, as less scopolamine and morphine could thus be used. Splanchnic block was much more easily performed with the patient under general anaesthesia, as psychic shock was thus abolished. In long operations he found that local and splanchnic anaesthesia were satisfactory only for a time, and less so towards the end, so that in this way it was a simple matter to increase the depth of general anaesthesia if necessary. Moreover, with a general anaesthetic there was less strain upon the surgeon and his assistants. There were certain disadvantages in local and splanchnic anaesthetics: they took time to inject, and the blood pressure tended to fall considerably. In one of his cases the fall was sufficient to be very

alarming, but the pulse rate was not diminished and the patient recovered. There was no doubt that splanchnic anaesthesia and regional block were great helps to the abdominal surgeon, both during the actual operation and afterwards, as the incidence of chest complications was greatly lessened, indeed almost to vanishing point, and shock and pneumonia had almost disappeared. In lower abdominal cases caudal block was also of use.

Mr. STANFORD CADE (London) stated that he had performed some 200 operations under splanchnic anaesthesia induced by Kappis's method, in which there were three types of danger. In the first, which was accidental and so avoidable, the drug might be injected directly into the blood stream unless repeated aspiration were performed before the fluid was injected. The second was physiological and consisted of the unavoidable fall of blood pressure after the injection of novocain. This could be combated by the prophylactic use of 1.5 c.cm. of pituitrin by hypodermic injection prior to the injection of novocain. The third danger was surgical and consisted in a delayed reaction—namely, a fall of blood pressure with a rise in the rate of the pulse; in his experience this danger was commoner when combined anaesthesia was used. On the whole he was opposed to ether or chloroform being given in combination with regional anaesthesia. The psychic effect could be dealt with by the rectal administration of paraldehyde or by the injection of trional with hyoscine, which caused a condition he found the nearest approach to natural sleep. Splanchnic anaesthesia diminished the mortality in cases of intestinal obstruction.

Mr. LOCKHART-MUMFERY (London) said that this meeting marked a definite event in the history of the surgery of the abdomen. Chloroform and ether were certainly not satisfactory in the case of long operations, while regional and local anaesthesia were handicapped by the fact that a really satisfactory local anaesthetic had not as yet been evolved. Regional anaesthesia was still in its infancy. He preferred combined anaesthesia with twilight sleep. He could see no advantage in parasacral over spinal anaesthesia, and the former was very much more difficult of application. The most satisfactory form of general anaesthesia was probably that advocated by Dr. Moots, but he was curious to know how a difficult case of intestinal obstruction could be dealt with under nitrous oxide and oxygen anaesthesia alone.

Dr. S. R. WILSON (Manchester) was anxious to know which was the best method to employ when so many had been described; personally he preferred to judge each case on its merits. The psychic condition of the patient was of the greatest importance, though apt to be entirely neglected. Even the routine administration of atropine was not without danger; he had had a case which showed most alarming symptoms after such an injection, probably due to adrenal exhaustion following the injection of atropine. It was quite conceivable that symptoms might follow when this drug was used in cases of thyroid disease as there seemed to be some connexion between thyroid disease and the condition of the adrenals. Nitrous oxide and oxygen would do all that a subcutaneous injection would do in cases where regional anaesthesia was employed. Only from the English-speaking races had there evolved a body of men who were specialists in the administration of anaesthetics; many of Professor Finsterer's difficulties were probably the result of the inexperienced being in charge of the anaesthetic. A drawback of complicated technique was that it consumed a considerable time in its application and a busy surgeon operating as he did in this country, in scattered homes and hospitals, would be seriously hampered by methods which involved great increase in the time necessary for each individual case. Interest was mostly confined to post-operative results, which were undoubtedly much better of recent years than formerly, no matter what type of anaesthesia was used.

Mr. M. MAMOURIAN (Ashton-under-Lyne) emphasized the necessity of progress, but thought that the emphasis laid on the necessity of team work was becoming grossly

exaggerated. The surgeon was not only the first violin but the conductor of the surgical orchestra, and consequently the work to be played should be decided by him and not by the anaesthetist, whose role was supplementary. He thought that much could be done in the schools by determining who was and who was not a good anaesthetist before letting a man take up a specialty regularly or occasionally for which he was temperamentally quite unfitted. Teachers should have clear ideas of the capacities of the men they were teaching, and should as far as possible prevent the round peg getting into the square hole.

Dr. F. H. McMECHAN (Avon Lake, Ohio) desired to record his appreciation of the debt overseas visitors owed to the British Medical Association for the chance of taking part in an international reunion. He reaffirmed his belief in the necessity of co-operation between the surgeon and the anaesthetist in the matter of operations, mainly for the benefit of the patient. Everything should be done to make operations as safe, as little unpleasant, and as satisfactory in their results, both immediate and remote, as was humanly possible; to that end co-operation was essential, so that surgeon and anaesthetist should have an intimate knowledge of each other's work and requirements.

Professor FINSTERER, replying, said that the discussion showed that the speakers were of the opinion that in major operations general narcosis with ether or chloroform should be replaced by nitrous oxide or combined anaesthesia. He referred to several papers that had been read, and commented on their main conclusions. The discovery that with endotracheal nitrous oxide-oxygen-ether anaesthesia the muscular relaxation, which was absent in the ordinary administration, could be obtained was very interesting. This relaxation could be more easily obtained by the injection of novocain into the anterior abdominal wall. A deep general anaesthesia was also necessary before introducing the catheter, and he would therefore prefer combined anaesthesia (injection of novocain into the abdominal wall and mesenteries and nitrous oxide) to Hower's method. He did not insist on regional anaesthesia, as his patients were given ether at once if they felt pain. In all major operations, even when starting with general narcosis, he produced complete local anaesthesia of the abdominal wall and mesenteries, so as to diminish the amount of general narcosis necessary and to prevent shock. This was absolutely necessary if nitrous oxide or narcylen could not be used for the general anaesthetic. In very old or cachectic patients he tried to avoid any ether, as it was in these cases that death from pneumonia was most to be feared.

# INTRAVENOUS SOMNIFENE ANAESTHESIA IN GASTRO-INTESTINAL SURGERY.

BY

IAN MACDONALD, M.D., C.M.,  
Huelva, Spain.

In abdominal and gastro-intestinal surgery anaesthesia has advanced with technique, and inhalation anaesthesia by modern methods in the hands of an expert anaesthetist, combined with Crile's method in the abdominal wall, gives most satisfactory results. In the ordinary case the surgeon obtains ease in operating and the patient awakes to an almost painless convalescence. But conditions arise when the surgeon must rely on ordinary, not expert, assistance, and in some countries the qualified specialized anaesthetist does not yet exist. Therefore, especially abroad, efforts are made continuously to eliminate the general anaesthetic or to reduce it to a minimum.

Before, however, adopting new methods surgeons will, I think, exact certain conditions of anaesthesia. The patient must be quite unconscious, the method must be simple, available anywhere without the need of specially trained assistants, the return to consciousness must take place in a reasonable time, and there should be no late toxic effects. These postulates place local anaesthesia alone, or the splanchnic block outside practical anaesthesia. The results of the latter in certain clinics are

excellent, in others patients complain most bitterly during the progress of the operation. Splanchnic anaesthesia also usually requires an extra and specially trained assistant. Besides, the objection that the deep bilateral insertion of the long needle constitutes an "anaesthetic operation" seems justified, as some anaesthetists give a general anaesthetic before beginning the splanchnic block. Recently in France the experimental and clinical researches of Fredet and his associates on the use of somnifene in intravenous injection for surgical anaesthesia prove that by the use of this preparation general anaesthesia may be reduced to a minimum—in some cases it may be eliminated. Fredet's interesting researches demonstrate that the seat of action of somnifene is chiefly in the nerve centres; its effect on the liver and kidney is extremely small. He further found that in the commercial product of this name there are two constituents, one with a slow and needlessly prolonged anaesthetic effect. He has eliminated this body, and now employs only the other—namely, allylisopropylmalonylurea, the action of which is rapid and more transient. To obtain surgical anaesthesia with this product it must be combined with morphine, or with morphine and scopolamine. In some cases nothing more is needed, but as a rule a small amount of a general anaesthetic is used to make and to close the incision. The technique of Fredet's method is as follows:

1. A hypodermic injection of morphine is given, varying from a minimum of 1 cg. up to 2 cg. as a maximum. It is advantageous to associate scopolamine with the morphine in doses varying from 2/3 mg. as a minimum up to 3/4 mg. as a maximum, according to the weight of the patient, and whether his general state is cachectic or satisfactory.
2. Twenty minutes later as a minimum interval, or forty-five minutes as a maximum, after the morphine-scopolamine injection, the intravenous injection of allylisopropylmalonylurea is made in a vein at the bend of the elbow with a fine needle and very slowly; three minutes at least should be spent in the injection. The dose is calculated according to weight, age, and the general state of the patient. Generally in fairly robust adults 1 cg. per kg. of body-weight is used, never passing 0.07 gram; personally, we have never passed 0.06 gram. In aged or cachectic patients 0.04 or 0.03 gram should be enough. Ampoules of the drug may be obtained containing 0.01 gram in each cubic centimetre of water.
3. Five minutes after the intravenous injection a small amount of chloroform or ether may be given to permit the incision being made about ten minutes after the intravenous injection. During the operation the general anaesthetic can often be dispensed with, to be resumed should the patient move and at the end to facilitate the suture of the wound.

This technique in practice is extremely simple, the anaesthesia is excellent, post-operative vomiting very rare. Patients awake four or five hours after operation to fall asleep quietly again. Excitement, which was frequently observed after somnifene anaesthesia when first used, is often quite absent with the latest preparation. I have used this anaesthesia in 33 cases during a period of two years, and, though it has not replaced routine methods, it is my choice in two types of cases—when the patient is a bad risk from pulmonary complications or from probable hepatic and renal insufficiency, and again when we are certain the operation must be prolonged. Thus I have used it in most types of gastric operations—gastro-enterostomy, gastrectomy, Balfour's operation combined with pyloroplasty and duodeno-jejunostomy, colectomy, and the prolonged operations needed for the cure of gastro-colic fistulae. In the tedious operation for large ventral hernia in a bronchitic patient and in exploratory operations when cancer is inoperable it has served me well. In several cases of gastro-enterostomy in most debilitated patients, by the addition of some local anaesthesia of the wall, no general anaesthetic was required. In a case of colectomy of the sigmoid for a ring carcinoma neither local nor general anaesthesia was employed; the patient slept deeply, never resenting the inevitable drag of the mesentery during mobilization of the descending colon, which was anastomosed to the rectum by Mayo's tube method. He never vomited afterwards; the pulse never passed 100. One death occurred in this series of cases in a case of intestinal obstruction, the fatal result being in no way connected with the type of anaesthesia. In 9 cases no general anaesthetic was required. In the others, when chloroform or ether was required to make or close the incision or during the progress of the operation, the

quantities used varied from 8 grams (3 drachms) of chloroform to 50 grams (1½ oz.) of ether. Only in two cases were these amounts exceeded. These anaesthetics were always given by the open method, so that in a hot country where evaporation is rapid patients did not actually inhale these amounts in full. Novocain was generally injected into the recti muscles, 6 oz. of a 1/2 per cent. solution being rapidly administered with a Babcock's self-filling syringe.

Of the 33 cases the results of the anaesthesia and the after-state of the patients were excellent in 29. In 4 cases some post-operative excitement occurred, which was very marked in one alcoholic patient in whom 6 oz. of ether had to be used. In the 3 other cases the agitation was slight and very soon over. With the most recent preparation patients usually awake five or six hours after operation to fall asleep quietly again, and excitement is absent. In my experience, the more cachectic the patient the better the result with this anaesthesia. Though not replacing routine methods, it is at present my method of choice in the type of case I have described. I believe it to be of incontestable value, especially for the isolated surgeon far from the large centre who cannot have the aid of expert anaesthetists.

## Memoranda;

### MEDICAL, SURGICAL, OBSTETRICAL.

#### POTASSIUM CHLORATE AND CONGENITAL GOITRE.

CONGENITAL goitre was first recorded in 1796; since then several hundred cases have been reported, the vast majority from goitrous districts on the Continent and America. H. H. Skinner in 1924, in the *Journal of the American Medical Association*, reported 12 cases—all, however, from goitrous mothers; he mentions 96 cases from sixty goitrous parents reported by Denne and Richard, and 130 cases collected from the literature by Thévenot in 1909.

In England, however, very few cases have been reported; in fact, I have been able to find records of only 6; of these, 4 occurred in Derbyshire and Cumberland, where goitre is not uncommon. The remaining 2 were reported by Sir J. Y. Simpson and A. R. Simpson, in 1855 and 1866 respectively. The mothers of these two cases had been taking potassium chlorate throughout their pregnancies on account of previous abortions or stillbirths. The parents were healthy and apparently did not reside in a recognized goitrous area.

Other cases must have occurred, but of those cases I have found recorded the mother in 33 per cent. had been taking potassium chlorate; if the cases from Derbyshire and Cumberland are excluded the percentage is 100. These numbers are too small, and even with the two cases I now record may merely be examples of coincidence.

Mrs. S., pregnant for the sixth time, stated that there was a family tendency to miscarriage, stillbirth, and neo-natal death. Her mother's first three children were either stillborn (two) or died in early infancy (one); these were followed by three boys and three girls. The girls all married.

K., the eldest, had first a stillborn boy, and secondly a boy who lived three days. She then took potassium chlorate and had four healthy children.

M., another sister, had a miscarriage at six months and an abortion at three months. She then took potassium chlorate throughout her next pregnancy until the thirty-eighth week, when labour was induced, a female child with a goitre, but otherwise healthy, being born; a subsequent pregnancy, during which she again took potassium chlorate, resulted in a healthy non-goitrous boy.

Mrs. S., the remaining sister, suffered from albuminuria in her first two pregnancies; in the first a macerated foetus was born at term; in the second the foetus (drowsical) was born at the eighth month. In the third pregnancy there was no albuminuria, but the child was stillborn at term. In her fourth and fifth pregnancies she took potassium chlorate. Premature labour was induced at the thirty-eighth week, and living healthy children were born. Throughout her sixth pregnancy she took potassium chlorate (gr. x thrice a day). She did not weigh it, but helped herself with a spoon to what she thought was enough. There was no albuminuria. Labour, in spite of deficient flexion, was easy. The child, a girl, was normal except for a large bronchocoele, filling up the whole neck; the swelling was soft and at first ill defined. For the first twenty-four hours the baby's colour was not good;

beyond this there was no difficulty in deglutition or in respiration. By the third day the swelling was smaller; the lobes of the thyroid gland extending on either side up under the ears were well defined. The enlargement steadily diminished in size and by the eighth week all obvious enlargement had disappeared.

The goitre in M.'s child was also transient.

There was no previous history of any goitre in the family. No Wassermann test was performed, but neither the mother nor her children showed any stigmata of syphilis.

Potassium chlorate reacts with iodine to form the iodate, and I suggest, as a possible explanation, that the prolonged administration of the salt may result in some of the maternal iodine becoming "fixed" and not available for utilization by the foetus, and that the enlargement of the foetal thyroid is an endeavour on its part to obtain and utilize the necessary iodine for its internal secretion. Such an explanation seems capable of being tested, and the results, if confirmatory, would throw some very interesting light on the causation of goitre in general.

Southsea.

R. K. WHITE, M.R.C.S.

#### HERPES AND VARICELLA.

In view of the relationship supposed to exist between herpes zoster and varicella, it may be of interest to report three cases, supporting this view, which I have seen during the past three years.

*Case 1.*—On September 19th, 1923, a married woman, aged 26, developed intercostal herpes. On October 4th (that is, fifteen days later) her child, aged 5 months, was seen with a typical attack of varicella.

*Case 2.*—On March 17th, 1926, a man, aged 79, developed supra-orbital herpes, which ran a rather severe course, and which left considerable scarring. On April 1st (that is, fifteen days later) his grandson, aged 2, who was living in the same house, developed varicella. The next day his granddaughter, aged 7, also showed signs of a mild, though typical, attack of chicken-pox.

*Case 3.*—On March 24th, 1926, a child, aged 13, was seen with intercostal herpes, and on April 11th (that is, eighteen days later) her sister, aged 11 months, fell ill with chicken-pox, exhibiting a profuse rash, with the typical distribution of the latter disease.

Apart from the herpes, no other source of infection could be traced in any of these cases. Conclusions cannot be drawn from a few cases, but it certainly seems a very remarkable coincidence when, in one practice, in a short time, three cases of this nature are seen.

Ibstock, Leicester.

W. J. MELDRUM, M.B.

#### CEREBRAL SYPHILIS: CONVULSIONS: DEATH.

The following case seems of sufficient interest to warrant recording.

W. J. V., a farm hand aged 45 years, was seen by me at 6 a.m. suffering from "fits." The history given by his wife was that he had been quite well until a week previously, and had since been "queer"; he had complained of headache, had "looked ghastly" at times, and threatened to throw himself out of the window. He had continued at work, however, until that morning, when on getting up he "had a fit." He had had no previous illnesses except malaria. He had served twelve years in the marines, and had seven healthy children. His wife gave no history of miscarriage or stillbirth.

He was found to be a muscular man, extensively tattooed. Every two or three minutes he had a convulsion, at first tonic, then clonic. There was no opisthotonos or rigidity of the neck or jaw; between the convulsions he was stuporose and could not recognize persons or obey orders. There was no paralysis or weakness of the face or limbs; the knee-jerks were brisk and equal and both plantar reflexes were normal. The cranial nerves appeared normal; the pupils were equal, moderately dilated, and reacted well to light; the fundi were normal. The heart, lungs, and abdomen were clear and the bladder was empty. There was no penile scar.

An injection of 1/4 grain of morphine and 1/200 grain of hyoscyne had no apparent effect on the convulsions. He could not be moved to hospital owing to the inaccessibility of his cottage. At 10 a.m. his condition was unchanged, but he appeared so cyanosed that I removed 20 oz. of blood by venesection and gave him 1 grain of calomel. At 6 p.m. he was obviously moribund; the fits had continued all day and he was then pale, clammy, and with a slow deep respiration and thready pulse. He died at 9 p.m.

A post-mortem examination was refused. The Wassermann reaction of the blood was found by the Hampshire county health authorities to be strongly positive.

The rapidity of the fatal issue and the entire absence of any localizing signs would seem to be the chief points of interest.

Lynton, Hants.

N. M. GOODMAN, M.B.

## A MEDICAL REVIEW OF SOVIET RUSSIA.\*

## IV.—CHANGE IN TYPE AND INCIDENCE OF DISEASE.

BY

W. HORSLEY GANTT, B.Sc., M.D.

(Formerly Chief of the Medical Division of the American Relief Administration, Leningrad Unit.)

## PART I.

MODIFICATIONS in disease have taken place all over the civilized world as a result of the war, influenza pandemic, and social changes, but not on the same great scale as in the Union of Soviet Socialist Republics (Russia). In no other country were the conditions so bad, and in no other country were the changes in morbidity so enormous. Some diseases became epidemic, others remained unchanged, and a few disappeared altogether.

We have been able to see in Russia the effects of war and famine on all kinds of diseases—surgical, internal, nervous, etc. Some of these changes have been so remarkable, so little has been written about them (even in Russian, almost nothing in English), that I have, during my two and a half years in Russia, collected these facts with a great deal of pains. An enormous number of original MSS., official statistics, and Russian medical articles have been gone over for this purpose, and a certain amount of unpublished detail is included.

The sources of information have been: a large number of original articles written by eminent Russian specialists in the various branches of medicine during the famine, and handed to the author in 1922; the records of the American Relief Administration; inspection trips and observations in the various parts of Russia; statistics of the Soviet Department of Public Health.†

In past wars the greatest destructive element has been disease. Only in the great war and in the Franco-Prussian war of 1870 have the deaths from wounds and from disease been nearly equal. Russia was the exception, if we consider the civil war also; for in 1918-20 there were more deaths from disease than from both the world war and civil war. Dr. Semashko states that, of the 14,000,000 men mobilized, 11,000,000 were lost through wounds and disease together. In 1828 Russia lost in the Russo-Turkish war 80,000 from disease and 20,000 in battle; in 1878 she lost 86,000 from disease and 16,000 in battle (Viry); and in 1917-20, although accurate figures are not available, it is estimated (Karefakorbut) that 20,000,000 Russians died, and in 1917-24 40,000,000 died, only a small percentage of which could have been due to the casualties of battle.‡

## FACTORS.

The limits of this paper make it possible merely to enumerate the factors underlying the morbid changes. The war in Russia brought with it the usual disease-producing concomitants of war—restriction of food, disorder, physical and mental suffering. These factors were of much greater magnitude in Russia than in any of the other nations. They combined to produce a tremendous effect on the health of the people, probably involving larger numbers and causing more disease than any other war or calamity in the medical history of Europe.‡

From 1914 to 1917 the decline in living conditions in Russia was similar to that in the other combatant nations; from 1917 through 1919 there was civil war of greater magnitude and destruction than the previous world war, involving nearly every person in Russia; and from 1919 into the summer of 1923 there was famine and starvation

affecting three-fourths of the people, and accompanied by epidemics of typhus and relapsing fever afflicting one out of every four adults, and of smaller epidemics of cholera and small-pox. These events completely smashed Russia, to say nothing of the other changes consequent upon two social revolutions. During part of this period everyone led the most primitive life and suffered from indescribable physical, mental, and moral hardships. Since 1922 there has been a gradual return toward normal life for the great mass of the Russian people.

**National Resistance.**—While the disease-producing factors were greater in Russia, the national resistance was less than in the other European countries. (Under this term are included those forces at the disposal of a nation for fighting disease, such as medical personnel, hospitals, field equipment, public health education, national finances.)

**Shortage of Doctors.**—Although the individual Russian doctor was well educated, the relative number of doctors in pre-war Russia was smaller than in any other civilized country.\* The mobilization of doctors and the large number of deaths among them left many districts entirely without medical assistance. For example, in 1921, when the epidemics were raging, in the Penza Government on the Volga, where one of every twelve people was down with fever, there was only one doctor for the 180,000 people.‡

A discussion of the hospitals has already been given.‡ The public health organization which the Soviets inherited from the Tsarist regime was almost nil, and there was thus a strong contrast between Russia and such countries as Germany and Finland. These two countries also were devastated by war, revolution, famine, and disorder, and epidemics appeared in them at the same time as in Russia, but thanks to their highly organized public health systems, and the general education and cleanliness of the people, typhus was soon checked.

## VITAL STATISTICS.

The following table shows the high death rate and low birth rate which resulted during the bad years in Russia, as compared with other European countries. The death rate for 1920-22 was, according to Professor C. A. Novosilsky and other Russian authorities, much higher than the recorded figure of 33.2; in many parts of Russia it reached 85 during the worst period.

TABLE I.—Birth and Death Rates, 1913 and 1920-24.

The figures are taken from the Annual Reports of the Registrar-General of England and Wales; from the *Statistisches Jahrbuch für das Deutsche Reich*, 1925; and from the records of the "Statbure," Leningrad. The figures for 1913 are for European Russia, exclusive of Poland and Finland.

\* Average for 1922-23 for R.S.F.S.R.

† Figures for U.S.A. include only the States in the registration area.

The populations of the chief European countries have doubled or trebled during the past century, as a result of the reduction of death rate.‡ This has been brought about mainly by the control of infectious epidemics and the lowering of infantile mortality.

\* The proportion of doctors in Russia was 1 to 6,000; in Germany, 1 to 1,500; in Great Britain, 1 to 1,400; in United States of America, 1 to 800. Many young doctors have been graduated since the revolution, so that the number of physicians in 1923 in Soviet Russia was 29,000, as compared with 14,000 before the war.

\* Previous papers on medical and scientific work in Soviet Russia by Dr. Horsley Gantt were published in the *BRITISH MEDICAL JOURNAL* in 1924: I. A Review of Medical Education in Soviet Russia, vol. i, p. 1055; II. Hospitals and Health Conditions, vol. ii, p. 336; III. Scientific Work, vol. iii, p. 633.

† I am indebted to Doctor Semashko and other officials of the Public Health Department for the unrestrained use of their figures. See also N. Semashko: *Health in Russia*, *Dokl. med. Nauch.*, 1924, Nos. 4, 7, 8, 11, 17, 18, 22, 27, 32, 37, 46, 51.

‡ Sir Humphry Rolleston called attention in 1916 to some of the factors of war in producing disease (*Practitioner*, January, 1916), and in 1920 to some theories as to the change in type of disease. The reader is referred to these for a fuller discussion and bibliography.

TABLE II.—Population.

|                   | 1800.      | 1910.      |
|-------------------|------------|------------|
| Great Britain ... | 16,000,000 | 44,000,000 |
| France ...        | 27,000,000 | 39,000,000 |
| Italy ...         | 17,000,000 | 34,000,000 |
| Sweden ...        | 2,000,000  | 5,000,000  |

A decline in death rate has taken place also in the decade 1914-24, except in Russia. However, in 1918-19, in practically every country for which we have any record the death rate equalled or exceeded the birth rate, owing to the pandemic of influenza. Although racial and other conditions affect the birth rate, it has been also influenced in Europe by the disastrous circumstances following the war, and in America by increased standard of living and of economic pretensions.

#### FAMINE AND DEFICIENCY DISEASES.

In addition to the underfeeding of the poor and the general lack of vitamins always present in civilized nations, there was during the world war, in nearly all the combating countries, a widespread caloric deficiency, especially marked in proteins, fats, and milk. In Berlin, in 1917, the rations fell to 1,400 calories.\* In America this shortage lasted only one or two years, and to a very limited extent, but in Europe for a much longer time, and in Russia—the Capital of Famine—until 1924, and affected nearly everyone; at one time about 20,000,000 were starving, and in 1920-22 about 10,000,000 died from starvation.

#### Food Shortage in Russia.

In order to explain the nutritional and other diseases which arose during the famine period I shall give a few details concerning the food shortage. This deficiency began in 1915. After the Soviet revolution in 1917 people in the cities were rationed, and there was little possibility of buying more food as money was abolished and barter prohibited until September, 1921. After this famine reigned. The official ration for the civil population of Leningrad in 1918, 1919, and 1920 is given by a professor of medicine as follows: from 272 to 611 calories, depending upon the employment. The Red soldier who was not in active service was then receiving 1,467.6 calories instead of the normal 4,300. In 1921 the civil ration was raised to 1,500 calories, with a proportion of 75 per cent. carbohydrates, 17 per cent. proteins, and 8 per cent. fats. The quality was poor, consisting mainly of coarse black bread, salt herring, and potatoes, and later of grits made of millet. Salt as an article of diet was absent.

#### Results of the Famine.

A leading internist of Leningrad gives the following as results of the famine: (1) General loss of weight of 20 to 40 per cent., and the entire disappearance of fat people. (2) Decrease in the capacity for mental work and a decrease in mental activity manifested by apathy, inability to concentrate, impairment of memory, weakness of will, a dulling of the feelings, especially of compassion, love, and the desire to be clean. (3) The development of the famine diseases, "hunger oedema" and "hunger cachexia." These showed a mortality of 50 per cent. (4) The increase in deficiency diseases such as scurvy, noma, and rickets. (5) The increase in some gastro-intestinal diseases—as meteorism, peptic ulcer, acute colitis, and occlusions caused by the indigestible food. These will be discussed under Internal Diseases. (6) Anthropological changes (to be discussed later).

The following is another description of famine disease which I have abstracted from an unpublished account given me by Professor Chernoroussky of the Leningrad Medical Institute:

Marked insufficiency of food lasting for a long time caused rapid loss of weight and splanchnoptosis. When this loss reached a certain degree it resulted in a definite disease—"famine inanition." Typical early symptoms were decrease of sexual activity; in men decrease of libido and impotencia, and in women amenorrhoea; a relaxation of sphincters, particularly of the bladder, causing a frequent desire to micturate.

Further decrease of nutrition led to a non-albuminous oedema, characterized by weakness, apathy, subnormal temperature, bradycardia, anaemia, and polyuria. There was

disturbance of metabolism and an alteration of the capacity of the tissues to retain water.

Famine disease which was not accompanied by oedema ("famine cachexia") showed more pronounced nervous symptoms, and its course was more acute and serious. Professor Chernoroussky concludes that the oedema has a compensatory value.

#### Gastro-intestinal Disorders.

The change in the nutritional conditions (decrease in proteins and fats, relative increase in carbohydrates, and great increase of indigestible residue) resulted in traumata of the gastro-intestinal tract, and a marked increase in hyperacidity and hypersecretion and gastric and duodenal ulcers; on the other hand, there was a decrease in gastritis, appendicitis, and constipation.

#### Scurvy.

Scurvy was one of the deficiency diseases least affected by the famine. It was more often seen in hospitals and kitchens where the inmates received a fairly ample caloric ration than in those in whom starvation was more marked but who were not confined to an institution. This was probably because they satisfied their appetite by eating berries, bark, leaves, etc. Scurvy was sometimes seen in the American kitchens where the children received cocoa, sugar, white bread, and evaporated milk.

#### Noma: Rickets: Pyorrhoea.

Noma increased enormously during the famine, and this was thought to be due to an abrasion resulting from coarse food (as wheat chaff) in a debilitated person. In a hospital at Syzran on the Volga which I inspected in 1922, 20 per cent. of the children had noma. It was always fatal. During the famine period 80 per cent. of the children were said to have rickets. In 1926 it is less prevalent, though still above the pre-war rate. This disease had also increased eightfold in Germany between 1916 and 1923. In Russia I did not see or hear of the keratomalacia and blindness which were present in Germany, owing to the food deficiency, in 1923. Pyorrhoea, which is so common in America, is rarer in Russia, although it has increased markedly in the past few years.

At the present time all these deficiency diseases have practically disappeared, and the feeding conditions are back to what is normal for Russia.

#### ACUTE INFECTIOUS DISEASES.

##### Typhus and Relapsing Fever.

The lice- and insect-borne diseases, such as typhus and relapsing fever, and plague had practically disappeared from the earth except as epidemics until the world war. With the squalor and malnutrition following the war the first two of these diseases assumed epidemic proportions in Eastern and Central Europe. Even in such ordinarily well ordered countries as Germany and Finland there were epidemics of significant size in 1917-19—for example, there were over 3,000 cases of typhus in Germany in 1919.<sup>5</sup> In Poland these epidemics were of enormous size, and in Russia, where lice were universal, practically everyone who was not immune was attacked (35,000,000 cases of typhus and relapsing fever together in Russia followed the world war).

Wherever there is constant dirt, lice, and overcrowding, typhus is likely to be present (for example, New York, Ireland, China, India). When these conditions become universal the disease spreads from an endemic into an epidemic. War furnishes ideal conditions for its spread. Sir Humphry Rolleston, former Surgeon Rear-Admiral in the British Navy, says:

"War, by massing together in close quarters large numbers of men, and especially of young recruits, facilitates the spread of infection, and thus fevers which in peace are endemic or sporadic become epidemic; this has been the universal experience, as was shown in the case of typhoid fever in the South African war, of typhus in Serbia, and of paratyphoid and, to a lesser extent, of cerebrospinal fever among our own men during the present campaign."

Famine also has some effect on the spread of these epidemics. It has often been noticed in Russia that they coincided with famine years. In the recent famine the incidence of the epidemics was remarkably greater in those

districts where the food shortage was most pronounced. For example, in Tsaritzan and Leningrad districts, where the famine was very acute, the number of infectious diseases was much greater than in the adjacent Don and Kopersky districts, even though the population of the two latter was two or three times as great. The only explanation that could be given was their greater food supply (H. Beeuwkes).

TABLE III.—Correlation of Food, Cleanliness, and Infection for the City of Leningrad.

| Year. | Population. | Official Ration—Calories.* | Amount. | Days. | Population. | Hospitals per 100 Patients. |
|-------|-------------|----------------------------|---------|-------|-------------|-----------------------------|
| 1916  | 2,317,851   | 3,000                      | ?       | 100   | 12.3        | 6.3                         |
| 1918  | 1,434,737   | 1,800                      | 100     | 50    | 21.8        | 9.3                         |
| 1919  | 700,000     | 1,500                      | 25      | 14    | 50.1        | 17.8                        |

\* The actual number of calories received was much lower than the official figures.

The recent epidemic of typhus in Russia was probably the largest on record. The last important epidemic before this was that of 1880-81, when there were 15,000 cases in Leningrad and approximately 3,000,000 in the whole of Russia.

TABLE IV.—Number of Cases of Typhus and Recurrent Fevers, with the Rate per 10,000 Population.

| Year.            | Typhus Exanthematicus. |       | Typhus Recurrens. |       |
|------------------|------------------------|-------|-------------------|-------|
|                  | No. of Cases.          | Rate. | No. of Cases      | Rate. |
| 1913             | 105,637                | 7.2   | 28,773            | 2.0   |
| 1918             | 141,633                |       | 16,662            |       |
| 1919             | 2,240,858              |       | 227,927           |       |
| 1920             | 2,667,500              |       | 1,030,624         |       |
| 1921             | 545,587                |       | 628,199           |       |
| 1922             | 1,556,312              | 158.9 | 1,675,120         | 171.0 |
| 1923             | 245,876                | 18.4  | 253,130           | 18.9  |
| 1924             | 126,946                | 9.5   | 49,586            | 3.7   |
| 1925 (Jan.—June) | 50,000                 | 3.9   | 10,000            | 0.7   |

These official figures are far too low for the years 1918-22; in 1923, when statistics had improved, we found that they should be multiplied by a factor of 2 to 4 to obtain the correct number.\*

These epidemics spread from the south northward, affecting the towns more than the country, and reaching their peak during the famine years. The subsidence may be attributed not only to improved living conditions but to the fact that practically everyone who was not immune had been attacked, and perhaps also, as Sir Humphry Rolleston points out, to the attenuation of the infecting organism. The mortality of typhus was 8 to 9 per cent., and of relapsing fever 4 to 5 per cent., but 14 to 17 per cent. if complicated by paratyphoid.

In 1919 compulsory vaccination of some of the medical personnel (1,000 in Leningrad) was carried out by Handi's method (citrate blood, or vaccine of heated defibrinated blood), and it was alleged that among the vaccinated the morbidity was only one-fifth as great as in those who were not vaccinated, and that no deaths occurred among them.

#### Typhoid Fever.

In the history of wars, only in the last great war has typhoid fever been an insignificant factor as compared with the casualties from wounds. During the past decade this disease has not increased in Russia. Russian authorities state that there is an antagonism between typhus and

typhoid (Jakoleff). The absolute number of cases for the whole of Russia was:

|              |         |              |         |
|--------------|---------|--------------|---------|
| For 1913 ... | 374,862 | For 1921 ... | 308,000 |
| " 1914 ...   | 355,000 | " 1922 ...   | 391,815 |
| " 1918 ...   | 109,000 | " 1923 ...   | 142,012 |
| " 1919 ...   | 252,000 | " 1924 ...   | 166,399 |
| " 1920 ...   | 424,000 |              |         |

The mortality rate per 100,000 population was:

|                              |      |
|------------------------------|------|
| For 1913 ...                 | 25.7 |
| " 1922 ...                   | 31.7 |
| " 1923 ...                   | 10.0 |
| " 1924 ...                   | 12.4 |
| " 1925 (January to June) ... | 4.4  |

The mortality during the famine was low—only 4.5 per cent. Leningrad was formerly one of the worst of the large cities of the world for typhoid fever owing to its poor filtration system. Its rate in 1910 was 33.7, while that of the largest cities in America was 23.5, and in thirty-three large European cities it was only 6.5. Since the advent of the Soviet Government the chlorination system of some of the cities has been greatly improved, and the rate reduced in spite of the inefficient and worn-out sewage and filtration systems. For example, in Leningrad the rate decreased from 45.2 for the ten years preceding 1916 to approximately 20 since 1916, and for 1924 the rate was 14.6. The vaccination of two million people by the American Relief Administration and subsequent vaccinations by the Soviet Government may have helped.\*

#### Cholera.

Cholera reached its maximum in 1921, when 205,000 cases were reported, and the actual number was many times this. There were 93,232 in 1922, 159 in 1923, only 10 in 1924, and 9 in the first six months of 1925 (Dobreitser). Beeuwkes says: "The recurrence of cholera has increased in the past years, the intervals have become shorter, and the virulence has augmented." Altogether there have been eight epidemics in Russia since 1823. That of 1908 was much smaller than the recent one, although there were 200,000 cases. The mortality in 1908 was 59 per cent., in 1911 and 1915, when there were only a few cases, 48 and 27 per cent. respectively, and for the first three and a half months of 1921, according to Dr. Beeuwkes, 50 per cent. (A.R.A. Reports.) Transportation formerly was from India and Persia, but it is not known how the present epidemic arrived. Professor Jakoleff says (personal communication) that the organisms probably lie dormant in healthy carriers between epidemics, as they have been found in man in the South of Russia, and also in fish of the Caspian Sea. During the epidemic which coincided with the famine of 1892 the number of people who died of cholera (Hiss and Zinsser) was 800,000.

It is difficult to form an opinion as to how far the present epidemic was influenced by the six million vaccinations done in two million people (by the American Relief Administration) in 1922-23 with the Pasteur "tetra-vaccine" against typhoid, paratyphoid (A and B), and cholera. It is interesting to know that in this large number of cases not a single death was reported from the use of the vaccine, although there were some extremely severe reactions.<sup>†</sup> Castellani and Mendelson also had no untoward results in 170,000 Serbians who were similarly inoculated.<sup>‡</sup>

#### Small-pox.

Small-pox has always been serious in Russia, as there was no compulsory vaccination before the revolution. Only in 1919 was there a marked increase in the disease. The official figures given below should be multiplied by two or more during the famine years.

|          |         |          |        |
|----------|---------|----------|--------|
| 1914 ... | 94,000  | 1921 ... | 83,000 |
| 1918 ... | 57,000  | 1923 ... | 40,000 |
| 1919 ... | 166,000 | 1924 ... | 28,553 |
| 1920 ... | 98,000  |          |        |

The rates (per 10,000 population) were: 4.1 for 1913, 3.6 for 1923, and 2.1 for 1924. Since 1918 the mortality has been 10 to 20 per cent. The Soviet Government has made vaccination compulsory (decree of 1919), and now

\* In the city of Petrograd alone, in the three years 1918-20, there were registered in the hospitals 75,000 cases of typhus fever, and 25,000 cases of recurrent fever, or one-sixth to one-eighth of the population.

† In the above discussion ... included with typhoid as there were no accurate ... the two. Statistics for Russia are from J. Chernourouky, and "Statbura."

that it is manufacturing its own vaccines (in 1922 two million children were vaccinated by the A.R.A.) we may look forward to this disease being reduced to the limits of other civilized countries.

#### Dysentery.

With dysentery, as with typhoid and small-pox, there was no great increase during the famine and war years. The figures for the morbidity of this disease were:

|          |         |          |         |
|----------|---------|----------|---------|
| 1913 ... | 445,955 | 1921 ... | 197,000 |
| 1918 ... | 59,000  | 1922 ... | 365,691 |
| 1919 ... | 137,000 | 1923 ... | 239,231 |
| 1920 ... | 324,000 | 1924 ... | 338,567 |

The rates (per 10,000) were: 30.5 for 1913, 29.7 for 1922, 17.9 for 1923, 25.2 for 1924.\* In spite of there having been no marked change in morbidity, the mortality increased sharply after 1918, which was attributed to the famine and the quality of the food. In 1919 the mortality was 20 per cent., and in 1920-21 it was 63 to 70 per cent. The prognosis of patients with typhus was especially poor (Chernoroussky). The usual type was the Flexner; the Shiga type was rarer, and the amoebic was found only in the South of Russia, where there were many cases of hepatic abscess. In the treatment of the bacillary form excellent results were obtained with Lister Institute serum; but the Pasteur serum was of little value. Even better results were obtained from the vaccine treatment than from serum.

#### Summary.

To sum up the situation in regard to infectious epidemics, we can say that the epidemics of typhus and relapsing fever which coincided with the famine were probably the largest ever seen in Russia, that the cholera epidemic was exceeded only by that of 1892, and that the malaria epidemic which followed the famine was decidedly the largest of its kind on record in Russia. Small-pox was slightly increased during the first year of the famine, but typhoid decreased. There was a small epidemic of even the plague during the famine. Since 1922 all of these infectious diseases have markedly decreased, except malaria and children's infections, which have increased. In 1924 there were 2,198 cases of epidemic encephalitis as against 958 in 1923.<sup>10</sup>

#### MALARIA.

Epidemics of malaria, syphilis, and tuberculosis have followed on the heels of the deadly typhus, and they remain problems of the present Russia.

Malaria had always been prevalent—for example, in 1914 there were reported 3,170,547 cases; but in 1922 the disease spread over the whole of Russia, even to Archangel and Murmansk on the shores of the Arctic, where it had hardly been known before, and indeed the tropical form was seen so far north. The peak of the epidemic was reached in 1923, when over six million cases were registered, and this probably represents only one-third of the actual number. Whole villages in the south and on the Volga were stricken. The average number of cases per 10,000 was 216 in 1913; 474 in 1923, 421 in 1924, and 175 in the first six months of 1925 (Dobreitser). For thirty-eight years preceding the war the cases in the Moscow district numbered 80.5 per 10,000; the rate was 258 in 1921, and 600 in 1923, according to official reports. In Vologda, between Leningrad and Archangel (latitude 60° N.), 72 per cent. of the workmen of the Water Traffic there suffered from malaria; in Archangel before the war there were 10 cases per 10,000, and in 1923 410 per 10,000. The tropical form was much more common in the south than in the north (Siberia 1.5 per cent., Middle Volga 25 per cent., Caucasus 50 per cent., and along the Caspian 80 per cent. in 1923). The mortality was extremely high where the tropical forms were present; "in the absence of quinine and other methods of treatment it is even said to amount to 40 per cent. in some places."<sup>11</sup>

This unprecedented spread of malaria was probably

\* It is out that of the soldiers landing at Moscow as dysentery, 71 per cent. were either same error may have existed in Russia, has affected the figures as a whole. For connexion with those for typhoid, we see change in either series. (Practitioner,

brought about by the constant movement of enormous masses of people and hordes of refugees during the war, revolution and famine, and the lack of quinine and medical personnel. Several Russian authors mention, as additional factors, the general lack of sanitation, the destruction of drainage systems, and the decrease of cattle and tillage of the soil. Previous epidemics occurred in 1894, 1899, 1903, and 1908, but on a smaller scale. Each epidemic has come in the years immediately following famine, but not during the famine.

#### Characteristics of the Present Epidemic.

Dr. I. A. Dobreitser, in the Pan-Russian Congress of January, 1924, pointed out the following interesting facts. Before the war the highest incidence was in spring, after the war in September; a high autumnal incidence indicates malaria for the ensuing year. Anopheles has been found in the past few years on the shores of the Arctic, and in the Caucasian Mountains, 6,500 feet above sea-level, and it lives during the winter in the houses of the peasants. Sixty per cent. of the cases have occurred between the ages of 18 and 60 years. A large number of infants have recently been seen with malaria (in Samara 30 per cent., and in some institutes of Moscow and of Turkestan 80 per cent. of the total number of infants observed). During 1924 and the first seven months of 1925 malaria had receded somewhat from its peak of 1923, but when I was along the Volga in the autumn of 1925 tropical malaria was again spreading rapidly. In Saratov Professor Kusheff of the Malarial Station told me that malaria had then mounted during three weeks to equal its former highest record (1923), and that 80 per cent. of the cases were tropical—an alarming situation.

Of 5,322 malarial patients examined in the Leningrad district in 1921 the spleen was markedly enlarged in 5.6 per cent. Where the disease is endemic the spleen is said to be enlarged in a greater percentage of children than of adults, but here the reverse was true, for only 1.6 per cent. of the children showed marked enlargement (A. P. Zelheim).

#### Treatment.

In the pernicious forms excellent results were obtained by large intravenous doses of quinine hydrochloride (1 to 2 grams) repeated for two or three doses on successive days. Even advanced cases yielded to this treatment (Dobrotin). The disease was nearly always fatal when treated by the mouth. After intravenous injection the spleen often returned to normal in one or two days. In 1922 Dr. A. N. Dobrotin in Saratov showed me such a case; in a girl aged 12 with the pernicious form the spleen reached to the umbilicus, but three days after the first intravenous dose it was reduced to normal. Professor N. E. Kusheff, however, limits the intravenous method to the comatose forms, as death may rarely occur from its employment. He uses the following as a hypodermic injection:

|                        |  |     |         |
|------------------------|--|-----|---------|
| R. Quinine bichlor.    | ...  | ... | 10 gm.  |
| Methylene blue (Merck) | ...  | ... | 0.6 gm. |
| Aq. dest. q.s.         | ...  | ... | 40 gm.  |
| M. et sig.:            | 2 gm. hypodermically q.d. for twelve days; for following month 1.8 gm. per os. |     |         |

#### TUBERCULOSIS.

Tuberculosis was increased in all the combatant nations of Europe during and after the war. The peak of the curve was reached in England in 1918 (17.3 deaths per 10,000, compared with 13.6 in 1914); in Germany in 1918 (23.0, compared with 14.3 in 1914); in Austria in 1917 (43.2, compared with 25.9 in 1913); in Petrograd in 1920 (55.2, compared with 33.5 in 1913). The fact that such countries as Switzerland and Sweden, have shown a more constant death rate for the past decade puts the blame more on the conditions of war than on the influenza pandemic.

The extreme conditions of life caused a dying off of all chronics. This removal of the most susceptible was naturally followed by a low death rate from tuberculosis in most of the countries where the death rate had been unusually high, notably in Germany and Russia. Thus in Leningrad, which we may take as an index for Russia, the rate has fallen gradually to 26.9 in 1924—lower than in

1913. The following figures for other years have been furnished through the courtesy of Professor S. A. Novosilsky of the "Statburo," Leningrad:

|             |      |          |      |
|-------------|------|----------|------|
| 1881-85 ... | 54.8 | 1920 ... | 55.7 |
| 1909-13 ... | 36.9 | 1921 ... | 38.5 |
| 1917 ...    | 36.8 | 1922 ... | 41.0 |
| 1918 ...    | 38.6 | 1923 ... | 29.8 |
| 1919 ...    | 48.0 |          |      |

Current reports indicate that, although the death rate is lower, the disease is yet very prevalent. For example, in the universities where systematic examinations have been made, we get active tuberculosis in: Odessa, March, 1923, 6.9 per cent. of all university students; Kiev, November, 1923, 12 per cent. of all students; in 1924 another report, testified as to its accuracy by leading physicians there, gives 47 per cent. of the students.\*

#### SYPHILIS.

Not only during the war, but for the years immediately following, syphilis increased all over the civilized world, in neutral as well as in combatant nations—for example, Sweden and Denmark.† In Germany in 1923, according to Möller, syphilis had increased 20 per cent., or 100 per cent. between the ages of 18 and 25 since 1919.

In Russia there was not only every social reason why syphilis should increase, but another important one absent in other countries—the lack of means of treatment: there were no arsenicals and few institutes. Overcrowding and filth contributed their share toward the increase. Under such conditions (the augmented chances of infection and the lack of treatment) syphilis mounted until in 1922 Dr. Semashko said that 80 per cent. of the population was infected in some sections (L. H. Guest). In 1923 doctors from north-western Russia reported to me that 95 per cent. of the population of their districts were syphilitic and the available supply of arsphenamine was far too small. In the same year the disease was so prevalent that I saw many who had been infected other than by sexual means—primary lesions in the nose, etc., whole families infected by ordinary contact under the extreme conditions of filth.

In 1920-22 there were officially registered in Leningrad institutes nearly 12 per cent. of the total population as having venereal disease, one-third of which (that is, 4 per cent. of the total population) were syphilitic. The actual number of cases must have been considerably greater. During these three years arsenicals were given to only 5 per cent. of the cases registered.

Present reports indicate that syphilis has decreased since 1923. In the autumn of 1925 Dr. Semashko, Commissar of Health, told me that although syphilis had greatly decreased throughout Russia there were yet some places where 80 per cent. of the people were infected. Where systematic examinations have been made the figures are very low. Dr. Semashko says:

"An examination of 70,000 Red soldiers gave 0.4 per cent. syphilis and 0.7 per cent. gonorrhoea in Moscow, and 0.9 per cent. syphilis and 2.0 per cent. gonorrhoea in Leningrad, at the moment of examination; of 1,600 university students of Moscow, 1.2 per cent. syphilis; of Moscow workers, 1.5 per cent. syphilis, 20 per cent. gonorrhoea; of some of the worst villages, 12 per cent. syphilis."

The examination of whole student bodies gave: in Odessa in March, 1923, 1.9 per cent. of the total as venereal; in Kiev in November, 1923, 12 per cent. of the total as venereal, one-tenth of which (1.2 per cent.) were syphilitic. The proportion of women to men was 1 to 6. In American universities 5 per cent. of the total are said to be syphilitic, and 20 per cent. of those that enlist in the regular army (M. J. Rosenau). At the Soviet sanatoriums in the Caucasian Mountains the chief of the department (Dr. Kishkin) told me that 1.1 per cent. of the 20,000 patients there in 1925 were found syphilitic. These low Russian figures can probably be explained by the difference in the methods of examination, such as the omission of the Wassermann test, etc.

It is interesting to note in connexion with the treatment of general paralysis by malarial infection that Russian

psychiatrists have reported that there has been no decrease in this disease, although malaria has increased several fold.

An analysis of several thousand cases of syphilis at the Nachinson Hospital, Leningrad (April to September, 1925), gives the following<sup>12</sup>: Most of the cases were between 20 and 30 years; 52 per cent. were married. Only a small number were from the educated classes—6 per cent. had an average education, and 0.3 per cent. a higher education. Twice as many women as men contracted the disease innocently. Many answered that they received the infection from sisters, brothers, daughters, or friends, but 87 per cent. of the men admitted infection from prostitutes; 24 per cent. contracted the ailment while drunk. Most of the men said that they began to go with prostitutes at the age of 16, and that they began to have sexual intercourse when 9 years old.

## Rebichius.

### CHRONIC RHEUMATIC DISEASES.

Lona famous for the treatment of arthritic affections, Bath has been fortunate in its medical authors, such as John Haygarth (nodosities), William Falconer, Caleb Hillier Parry, and J. K. Spender, to mention a few only of those who have enriched medical knowledge by the records of their experience. That the present medical generation of this ancient spa have not rested on their oars is shown by their recent contributions to our pages and to other publications, and now the last year's President of the British Medical Association, Dr. F. G. THOMSON, and his colleague Dr. R. G. GORDON in *Chronic Rheumatic Diseases: Their Diagnosis and Treatment*<sup>1</sup> have brought out a well written and thoroughly practical summary of a subject which has been so much discussed that it is sometimes rather difficult to see the wood for the trees. This compact and clearly expressed handbook is divided into three parts, dealing with the clinical aspects, the common mistakes in diagnosis, and the principles of treatment respectively. In a brief summary of the etiological factors, the authors, while giving full weight to infection, set before the reader the reasons for considering that diathesis and personal idiosyncrasies play a disposing part; they also consider that primary osteo-arthritis is entirely due to strain and malnutrition of the joint.

While not attempting a scientific classification, for which the time has hardly arrived, the authors present a series of clinical pictures, including fibrositis, lumbago, sciatica, periarticular fibrositis, focal arthritis, osteo-arthritis, spondylitis, climacteric arthritis, and gout. The much used, and somewhat abused because vaguely used, term "chronic rheumatoid arthritis" is dropped, and for much of what it has covered "focal arthritis" is substituted, and may be welcomed as a reminder that the responsible site of infection must be sought and removed. This point is rightly emphasized, as is the futility of wasting time on palliative treatment, such as drugs and local applications. After removal of the causal focus the most efficient form of medication is said to be the freshly made chlorine mixture, which the late Burney Yeo recommended in the treatment of typhoid fever, other reputed intestinal anti-

\* From reports furnished by Mr. O. J. Frederiksen of the European Student Relief.

† Competent physicians in Sweden told me that they attributed this to increased movements of the population, increase of industrial life, etc., occasioned by the war.

<sup>1</sup> *Chronic Rheumatic Diseases: Their Diagnosis and Treatment*. By F. G. Thomson, M.A., Cantab., M.D., F.R.C.P. Lond., and R. G. Gordon, M.D., D.Sc., M.R.C.P. Edin. Oxford Medical Publications. London: Humphrey Milford, Oxford University Press, 1925. (Demy 8vo, pp. viii + 202. 8s. 6d. net.)

septica, with the exception of mercurial preparations, particularly in gout, being dismissed as "singularly ineffective." Climacteric arthritis, which is held to be chiefly of metabolic rather than of infective or degenerative origin, is described as a special and definite form, which usually begins in stoutish women about the time of the menopause, and is implanted on thyroid insufficiency, thus contrasting with focal arthritis, which is often associated with symptoms of hyperthyroidism. Early treatment is very successful, and consists in reduction of excessive weight, detoxication and improvement of the general tone, and the correction of endocrine deficiency.

The authors' apology for a certain amount of repetition, which is almost inevitable and sometimes useful, and for some degree of dogmatism, which the general practitioner, for whom the work is intended, will probably welcome, forestalls any possible criticism; indeed, there is none to make. The last section, on the principles of treatment, shows sound common sense, good judgement, and an entire absence of any tendency unduly to insist on the undeniable claims of Bath as a remedial spa.

### THOMSON'S "DISEASES OF THE NOSE AND THROAT."

In presenting a copy to the reviewer, Sir StCLAIR THOMSON inscribed as follows on the fly-leaf of his new edition<sup>2</sup> of *Diseases of the Nose and Throat*: "George III to Gibbon the historian: 'Another damned fat book, Mr. Gibbon! Scribble, scribble, scribble, eh, Mr. Gibbon?'" The author can well afford the jest against himself because there is here neither scribbling nor obesity, and though the third edition is larger than either its father or its grandfather, the increase is due to the natural expansion, both intrinsic and extrinsic, of the subjects treated. There is good reason to believe that had it not been for the inflexible opposition of the publishers the grandchild might have turned the scale a few more ounces still. Externally the new edition is shown by a change of colour from the familiar blue to green—not the dingy green of an old blue suit, but a placid shade indicating a green and vigorous old age.

The oesophagus, certain diseases of the nose, cocaine substitutes, and malignant disease of the larynx represent some of the more important items calling for revision and extension. An instance which shows the changing point of view is tonsillotomy, which at least received recognition in the first edition. In the second its funeral oration was pronounced, and in the third it has been decently interred. Although the author only refers in the preface to a few changes and additions it will be found that nearly every section has undergone some alteration, always with advantage.

It is a common experience to find that a writer, especially a medical writer, has exhausted all he has to say in a first edition and that later additions only result in a scrap-book. There is no such patchwork effect here. Fresh work has been introduced and sections rewritten with such skill that a perfect blend results. The art is only revealed by the dates of the references, which as before adorn the pages in profusion, and it is right to say here that Sir StCLAIR THOMSON has been particularly generous in acknowledging the efforts of his younger colleagues.

It was stated dogmatically in the review of the first edition that this is the best book of its kind in the English language, and there is every reason to ratify that opinion now, fifteen years later. It is therefore refreshing to find that the author betrays his humanity by an occasional slip of the pen, albeit they are of a nature that could mislead nobody. A single example is enough: he takes some trouble to make it clear that mucous polypi of the nose are not new growths, and in almost the next paragraph refers to them as neoplasms.

It may be permissible to conclude these remarks with a text from Edward Gibbon, whose name adorns the opening; Gibbon wrote: "The sophist of Antioch professes to admire the moderation of Sapor in contenting himself with so small

a portion of the Roman Empire." If Sir StCLAIR THOMSON has contented himself with a small portion of the empire of the human body, he has cultivated the study of it in a manner that may well excite admiration, and he has truly achieved his openly avowed intention of making a good book into a still better book.

### MEDICAL PATHOLOGY.

THE *Précis* of medical pathology by Drs. F. BÉZANÇON and A. PHILIBERT is the work of several authors, and is ultimately to consist of seven volumes. So far only two have been published.<sup>3</sup> The first treats of the common infectious diseases, and the second of diseases caused by spirochaetes, filterable viruses, and protozoa, of diseases whose cause is as yet unknown, of cancer, and of the intoxications. Pathology and morbid anatomy play only a small part in the composition of the work, which is in reality a textbook of medicine; indeed, far greater stress is laid on the clinical than on the laboratory side of the subject. For this reason it is not unnatural to find that the bacteriology, in particular, is poorly done, and is spoiled by the inclusion of a number of erroneous or unconfirmed statements, and by the omission of some well substantiated facts.

It is curious to find it said in the discussion of the diagnosis of enteric fever that a titre of 1/100 to *B. typhosus* or of 1/500 to *B. paratyphosus* B is significant, without the mention of the reactions encountered in inoculated persons, or the necessity of following the agglutination curve in doubtful cases. With such teaching as this it is not to be wondered at that mistakes in diagnosis are said to be not uncommon. Recently we had a striking example of this in the case of an officer living in Paris, who, on the basis of a Widal reaction, was told that he was suffering from typhoid fever; he—wisely as it turned out—hurried over to this country, only to find on a thorough investigation that the agglutinins in his blood were entirely referable to his previous inoculation with T.A.B. vaccine.

The classification of diseases adopted is not free from objection; dengue and trench fever are included under the spirochaetoses, whereas a disease such as spirochaetosis icterohaemorrhagica, of whose etiology there is no doubt, is omitted altogether. Scarlet fever is placed among the diseases of unknown origin; for this a reasonable case might be made out, but for the statement that the streptococci of scarlatina are identical with those from other sources there is no justification.

Some of the illustrations are poor and even misleading, but the book is well written and eminently readable. We doubt, however, if it is likely to find favour in this country.

### THE CHEMISTRY OF PROTOPLASM.

*The Effects of Ions in Colloidal Systems*,<sup>4</sup> by Professor L. MICHAELIS of Baltimore, contains the substance of various lectures given by him last year at certain American universities.

The application of the laws of physical chemistry to living protoplasm is one of the most difficult of the problems that at present confront physiology. The theoretically correct course would be for the chemists to enunciate the laws and the biologists to seek to apply them. In actual practice the biologists have had in many cases to establish physico-chemical laws to explain the phenomena observed in living matter. Professor Michaelis in particular has rendered outstanding service in helping to clarify the confused question of the fundamental nature of the process of adsorption. He apologizes in the preface for the fact that his book deals more with physical chemistry than with physiology, but points out that the biologists' problems are so complex that they are forced to help to organize certain branches of chemistry and physics which are most likely to be of service to physiology.

The book deals with the fundamental nature of the process of the adsorption of ions by colloidal systems. This problem is still very largely unsolved, but the author gives

<sup>2</sup> *Diseases of the Nose and Throat, Comprising Affections of the Trachea and Oesophagus*. By Sir StCLAIR THOMSON, M.D., F.R.C.P. Lond., F.R.C.S. Eng. Third edition. London: Cassell and Co., Ltd. 1926. (Med. 8vo, pp. xvi + 943; 379 figures, 12 colour and 12 black, and white plates. 55s. net.)

<sup>3</sup> *Précis de Pathologie Médicale*. Tomes I et II; *Maladies Infectieuses*. Par Fernand Bézançon et André Philibert. Paris: Masson et Cie. 1926. (Cr. 8vo, Tome I: pp. 539; 75 figures. Tome II: pp. 651; 91 figures. 28 fr.; bound, 34 fr. a volume.)

<sup>4</sup> *The Effects of Ions in Colloidal Systems*. By Dr. Leonor Michaelis. Baltimore: The Williams and Wilkins Company; London: Baillière Tindall and Cox. 1925. (Cr. 8vo, pp. 108; 7 figures. 12s. 6d. net.)

a very clear account of the salient facts that have been established. It is doubtful if anyone else could have summarized this difficult subject so shortly, simply, and yet so accurately. A considerable proportion of the volume deals with the interpretation of experimental results obtained by the author and his pupils.

All persons interested in the colloidal chemistry of protoplasm will find this book extraordinarily interesting and suggestive.

### THE PEAKS OF MEDICAL HISTORY.

In his attractive outline of the evolution of medicine, entitled *The Peaks of Medical History*,<sup>5</sup> dedicated to Lieut.-Colonel Fielding H. Garrison, Professor C. L. DANA of New York divides the history of medicine into seven periods—the pre-Hippocratic, the Hippocratic, the Alexandrian, the Galenic and post-Galenic, the Renaissance, the sixth of theories and speculations, ending with Jenner (1800), and the seventh of modern medicine down to the middle of the last century, the six peaks being Hippocrates, Alexandrian medicine, and so on. The oaths of the Hindu physician and of Hippocrates are printed, and the work is liberally and artistically illustrated; among the pictures is a rubbing from the breastplate of the leaden sarcophagus containing the remains of William Harvey in the vault of the church at Hempstead, made in 1880 by the late Weir Mitchell.

In a small space the volume contains a pleasant account of the great men of old, but the chapter on modern medicine, which is the most difficult to view in proper perspective, is perhaps the least attractive and certainly is the one most easy to criticize. Like all the works on medical history issued by the house of Hoeber, it is admirably got up.

### "BRAIN."

THE issue of *Brain* for July (vol. xlix, Part 2)<sup>6</sup> contains a paper on combined disease of the pyramidal and extrapyramidal systems, with special reference to a new syndrome, by Professor Lhermitte and Dr. Douglas McAlpine, from the Laboratory of Neuro-Pathology, University of Paris. A clinical and pathological account is given of a case showing a degree of spastic paralysis with extensor plantar responses, which in the later stages developed choreiform movements and rigidity of extrapyramidal type. This is followed by a review of the literature and a discussion of the pathological basis of choreiform movements. Professor Leonard S. Dudgeon and Dr. A. L. Urquhart describe an investigation of the viscera and muscles in nine cases of exophthalmic goitre. In eight they found in various muscles, chiefly the ocular muscles, lymphorrhages, exactly similar to those found in myasthenia gravis. They consisted of collections of lymphocytes with some plasma cells and endothelial cells, separating the muscle fibres; in some cases the neighbouring muscle fibres showed atrophic or inflammatory changes.

Dr. O. M. Duthie, of the anatomy department of Manchester University, records some observations on deep sensibility in continuation of the work of Professor Stopford. He examined the sensibility of twenty patients suffering from division of tendons in the forearm uncomplicated by lesions of peripheral nerve trunks. He concludes that division of nerve fibres proceeding along tendons results in only slight loss of deep sensibility, tactile pressure being chiefly affected. Drs. Henry W. Woltman and Alfred W. Adson, of the Mayo Clinic, record a case of abscess of the spinal cord which made a remarkable recovery after operation, and give a valuable summary of the literature of this rare condition.

Drs. Curt P. Richter and Leo Henry Bartemeier, of the Johns Hopkins Hospital, contribute an important paper

on decerebrate rigidity of the sloth. They selected this animal because its 'normal' posture at rest and during progression is a hanging one—that is, the opposite of the attitude of quadrupeds such as were employed by Sherrington in his experiments on decerebrate rigidity. They establish the interesting fact that the decerebrate sloth exhibits reflex hanging, thus bringing decerebrate rigidity into relation with normal posture. They draw some conclusions respecting the probable clinical counterpart of decerebrate rigidity in man.

### GUY'S HOSPITAL REPORTS.

THE second quarterly instalment of the 76th volume of the *Guy's Hospital Reports* opens with an obituary notice of Dr. G. H. Hunt by the Editor, who gives an account of the large amount of work his late colleague had accomplished in a comparatively short time. Dr. J. M. H. Campbell has expanded into an article the late Dr. Hunt's notes on heart disease and pregnancy based on 156 cases, which show that, provided the heart is not enlarged, mitral disease does not add much risk; when, however, there is cardiac enlargement the degree of risk depends on the amount of enlargement, and in auricular fibrillation the results are so serious that pregnancy should be prohibited. Dr. G. W. Rake describes a case of annular muscular hypertrophy of the oesophagus and shows good reason for his view that it is compensated achalasia of the cardia without dilatation. A curious point in Mr. W. E. Tanner's record of a case of dysphagia due to a posterior pharyngo-oesophageal pouch was the absence of any fetor of the breath, due, as is supposed, to the fact that the patient's addiction to neat whisky kept the pouch clean. Four short records of the association of chronic duodenal ileus with gastric and duodenal ulcer by the Editor and his colleagues are followed by a discussion of the indications for enterostomy and its technique by Mr. R. P. Rowlands. In recording a case of chronic volvulus of the pelvic colon simulating pyloric obstruction but correctly diagnosed by radiological methods before its successful excision, Dr. Hurst refers to Sir Arbuthnot Lane's demonstration that a volvulus is only the terminal stage of a condition which usually takes years to develop. Dr. F. A. Knott's experimental researches suggest that salicylates taken by the mouth exert hardly any antiseptic action on the bile; accepting Cartier's observations as to their strongly cholagogue action, they confirm Chauffard's view that salicylates alone are chiefly of use in non-infective cholecystitis and that hexamine should be added when infection is known or suspected to be present. About half of the number is occupied by the ninth of Dr. G. W. Nicholson's studies on tumour formation; it deals fully with endometriomas, though he modestly says that he has "only skimmed" the subject, the weary "length of which has dragged itself to rest."

### NOTES ON BOOKS.

DR. OSKAR TEICHMAN has compiled an interesting little book on *The Cambridge Undergraduate 100 Years Ago*.<sup>7</sup> His information is derived from sundry Cambridge publications of the period. Thus in 1823 a little book of poems and epigrams, called the *Cambridge Tart*, was published as a counterblast to the *Oxford Sausage*. From this anthology we learn that the dean of those days used to set impositions of a hundred lines of Homer for non-attendance at chapel; that the barber was on the college foundation like the cook, and had his shop inside the gates; that undergraduates attended hall at 3 or 4 o'clock in the afternoon in breeches and gaiters, subsequently retiring to a wine party and ending the evening with something hot. In the meantime the Fellows spent a couple of hours in the combination room, and if still more or less sober finished the evening with beakers of brandy. From time to time the undergraduate's life was enlivened by town and gown conflicts; and a particularly stirring attack by

<sup>5</sup> *The Peaks of Medical History: An Outline of the Evolution of Medicine for the Use of Medical Students and Practitioners*. By Charles L. Dana, A.M., M.D., LL.D. New York: Paul B. Hoeber, Inc. 1926. (6 x 9, pp. 106; 40 plates and 15 illustrations in the text. 3 dollars net.)

<sup>6</sup> Published in London by Macmillan and Co., and in New York by the Macmillan Company. Yearly subscription in this country 24s., to be sent to Messrs. Macmillan, St. Martin's Street, London, W.C.2. Price of this part 6s. net.

<sup>7</sup> *Guy's Hospital Reports*. Vol. 76 (Vol. 6, Fourth Series), No. 2, April, 1925. Edited by A. F. Hurst, M.D. London: Wakley and Son (1912), Ltd. (Med. 8vo, pp. 127-252; 6 plates, 20 figures. Annual subscription, 12 2s.; single numbers 12s. 6d. net.)

<sup>8</sup> *The Cambridge Undergraduate 100 Years Ago*. Compiled, with extracts and illustrations from contemporary sources, by Oskar Teichman, D.S.O., M.C., M.A. Cambridge: W. Heffer and Sons, Ltd. 1925. (Cr. 8vo, pp. vii + 108; illustrated. 4s. net.)

500 gownsmen on 2,000 "snobs" after the acquittal of Queen Caroline was described in the *Gradus ad Cantabrigiam* in a parody of Campbell, beginning "On Granta, when the sun was low." A later riot, the battle of Rose Crescent, was described in the metre of Macaulay's "Horatius" in an early volume of *Punch*; and Dr. Teichman gives us Calverley's acrostic poem, beginning "On pinnacled St. Mary's lingers the setting sun." There are interesting little chapters on the boating man, who before 1825 was chiefly an undergraduate who went for picnics and water parties, and had altercations and more or less sanguinary encounters with barges; on the reading man, for whom the writers of these skits and squibs have, naturally, small respect; on the sporting man, then known as the varmint man, who, after drinking much wine and indulging in Cyprian adventures—in Barnwell of all places—finds himself compelled to send for a surgeon, and is obliged to get an aegrotat. Dr. Teichman concludes his book with a useful index of colloquial or cant terms, and another of college nicknames. From this it appears that Hall was the gay college—the most lawless of all; Cats men were doves; men of Sydney owls; while for some unaccountable reason Johnians were always called Johnian hogs. There are illustrations in the book showing the academic costumes of Masters of Arts, Proctors, Fellow Commoners, and various other members of the University. The two distinguished classes of persons who wear top-hats with their gowns are noblemen and M.D.'s!

Otologists will be pleased to learn that Mr. RICHARD LAKE, though seldom seen amongst them now, still retains an active interest in aural surgery, and has exercised it by publishing in a book about fifty of his lectures and papers.<sup>9</sup> They range over the whole subject of otology, but they serve to recall in particular his pioneer work in the surgery of the labyrinth, work for which, although by no means unknown, he has scarcely received full credit. There is one feature in common to all which can scarcely escape notice, and that is his commendable brevity, for the whole book only contains 255 pages, and includes a number of illustrations. The precision with which the essential points in each article are packed into a few pages recalls vividly Mr. Lake's own forcible and vigorous personality. The book is disfigured by an excessive number of misprints; there is far more than a reasonable allowance, especially in the portions in French. In other respects it is presented in a very convenient form, and the younger generation would do well to read it carefully, remembering that it is natural there should have been some changes and advances since the dates of the earlier papers. Any otologist who takes a serious interest in the literature of the subject should show his gratitude to Mr. Lake for rendering his work accessible by keeping a copy in the study for reference.

In his monograph on the treatment of bronchial asthma by intravenous injections of peptone<sup>10</sup> Dr. P. BOOT reviews the articles published in this JOURNAL in 1917, 1918, 1920, and 1921 by Dr. A. G. Auld, and records his own observations on twenty patients treated by this method. Of the eighteen patients in this series suffering from asthma eleven were more or less improved and seven derived no benefit from it. While admitting that twenty cases are not sufficient to estimate the value of Auld's method, the author maintains that peptone has the power to suppress an attack of asthma, though not always to the extent desired, and therefore cannot be regarded as a sovereign remedy. The treatment has no effect on the blood picture. Dr. Boot attributes the success of peptone treatment to the more or less complete destruction in the blood of a substance which, according to Sturm van Leeuwen, produces contraction of the smooth muscle fibres, and so gives rise to an attack of asthma.

The third edition of Professor R. H. DENNETT's *Simplified Infant Feeding*<sup>11</sup> has been brought up to date, particularly with regard to the use of dried milk, the occurrence of acidosis, and the care of the hypertonic infant. The chapters on diarrhoea have been revised. As we mentioned when we reviewed the second edition on February 18th, 1922 (p. 274), the book is full of practical directions; it remains a valuable handbook of infant feeding.

## PREPARATIONS AND APPLIANCES.

### Decimal Ratios in Haemocytometer Rulings.

THE accompanying figure represents the central square of the ruling of a modified haemocytometer which in general construction is on the model of that of Thoma. It is designed to eliminate the necessity of calculation involved in the use of the latter instrument. For the enumeration of red cells a dilution of 1 in 200 is used, and an area of 1/5 sq. mm. (ACFH) is counted. To the number thus found it is necessary only to add four cyphers to obtain the content of 1 c.mm. of the original specimen. The percentage in relation to the normal—assuming this to be 5,000,000—is equal to the number of cells in 1/25 sq. mm. (ABFG or ACDE), for this

Dimensions: 1 mm. x 1 mm., divided vertically into fifth and twenty-fifths, and horizontally into tenths.

area will contain exactly 100 in the case of a normal specimen. For the enumeration of leucocytes a dilution of 1 in 10 is employed, and 1 sq. mm. is counted. To the number found two cyphers are added to give the total per cubic millimetre of undiluted blood.

The most rapid work can be done by using a 2/3 in. objective and a  $\times 10$  or  $\times 12$  eyepiece, as with this the areas can be counted comfortably in vertical columns (ABFG) without moving the slide. This arrangement, probably on account of its similarity to the accustomed order in the tabulation of figures, gives considerably increased facility. With the 1/6 in. objective, however, it is more convenient to count in squares of the size of ACDE, which are equal in area to the narrow columns (ABFG). An eyepiece ruling, similar in design but on a larger scale, is available. It is less tiring to use than stage ruling, as the marking is more pronounced; but it is necessary to employ an appropriate microscope combination and tube-length, in order to secure exactly equivalent values. The scale used is 7 to 1, which is intended for use with a 2/3 in. objective. For differential counting of cells or bacteria on a plane slide the eyepiece ruling, which is carried on a simple glass disc, may be used with any power of objective.

The instrument is obtainable from Messrs. Allen and Hanbury, Ltd. The eyepiece fitting is not supplied as standard, but may be had separately.

### A Desk for the General and Panel Practitioner.

Dr. E. W. Sharp (Bradford) has designed a desk to simplify the work of keeping medical record cards, and the book-keeping necessary for private patients. Eight drawers are provided, each of which will hold approximately 500 medical record cards, or 1,000 ordinary cards for private patients, together with index cards. The cards for private patients are arranged in three sections according as the accounts have to be posted, collected, or have been paid and no attendance is now being rendered. On the open part of the desk there is ample space for writing, and pigeon holes can be constructed at the back for storing certificate books. Part of the desk is closed and in it is a well containing a removable box, divided into four sections, the two front ones containing all the cards of patients, both private and panel, who are receiving attention, while those at the rear are used for storage. One side is devoted to patients who are being visited; on the other are kept the cards of patients who are attending the surgery for consultation. The cards of the patients who are being visited are divided by index cards showing the numbers 1 to 31 and the days of the week. By using two sets of these the cards can be changed from one week, or from one month to another. The daily visiting list is made up from the cards which are behind the index card of the particular day. At the end of the day the visits are entered up and the cards transferred to the next dates on which visits are due. Dr. Sharp adds that all the information is readily available while sitting in the desk chair, and the work of book-keeping is reduced to a minimum. The necessary index cards are made by Messrs. Reynolds and Branson of Leeds, and have the advantage of combining the day book and ledger. Prescriptions and treatment can be recorded on them and they are of the same size as the record envelope issued by the Ministry of Health. A complete year's accounts can be kept on each card.

### A Portable Mercury Sphygmomanometer.

The Baumanometer is a simple form of mercury sphygmomanometer with an ingenious arrangement to prevent spilling of the mercury during carriage. The makers claim that it is safe, portable, and efficient, and that the mercury does not oscillate at either systolic or diastolic pressures, so that it is well adapted to the auscultatory method of reading blood pressures.

Of the two types of sphygmomanometer—namely, the mercury and the aneroid—the latter is very widely preferred owing to its greater portability. The mercury manometer is, however, not only simpler but more accurate, inasmuch as it is not subject to errors due to changes in elasticity, etc. The makers of the Baumanometer (Messrs. Hawksley and Sons, Ltd., 83, Wigmore Street, W.1) claim that in their instrument there is no risk of loss of mercury during transportation, and that it is as convenient for use as the aneroid type.

SATURDAY, AUGUST 14TH, 1926.

## A HARVEIAN TRICENTENARY.

At its last meeting the Royal College of Physicians of London resolved duly to celebrate in 1928 the tricentenary of the first publication of Harvey's *De Motu Cordis*. This decision is amply justified by the importance of the occasion. Harvey's investigation into the physiology of the circulation of the blood had, indeed, been brought to a successful conclusion nine years before the publication of this celebrated book, and the truth of his discoveries had been accepted by many of his colleagues. In his eloquent dedicatory letter to the President and Fellows he wrote: "Having now for nine years and more confirmed these views by multiplied demonstrations in your presence, illustrated them by arguments, and freed them from the objections of the most learned and skilful anatomists, I at length yield to the requests, I might say entreaties, of many, and here present them for general consideration in this treatise."

The time was ripe for publication, and the dissemination of the truth all over the civilized world could no longer be delayed; the date of publication, and not that of the first statement of his views in the Farnham Lectures, is necessarily that of which the tricentenary is to be honoured. We have referred to the importance of the occasion, and by this we intend to lay stress not only on the value of the great discovery to the future progress of medicine and surgery, but still more on the method by which the discovery was made. This has perhaps attracted less attention than its importance merits in the intellectual history of mankind. The end of the sixteenth and the beginning of the seventeenth centuries were astonishingly fertile in the production of men of great mental power, and of these our country is proud to claim a large share. Shakespeare, Reginald Scott, Bacon, and Harvey were to be closely followed by Hobbes, Locke, Hooke, and Newton, while among their contemporaries on the Continent were Galileo and Descartes, to name only the greatest. Reginald Scott, like Harvey a "man of Kent," stands out in the sixteenth century conspicuous for the modern spirit of his writings. His *Discoverie of Witchcraft*, published in 1584, in which he ridiculed and disproved the charges on which poor old women were sentenced to be burnt or drowned, was itself afterwards condemned to the flames by a demonologist king who had imported the practice of witch-baiting from Scotland. For a generation Scott had no successors. It is of interest to note that to Harvey in 1634 was committed the duty of examining four poor women known as the Lancashire witches. He found no devil's teats or other imagined horrors, and as a result of his report of their normality they were pardoned—for crimes of which they were guiltless.

Bacon's *Novum Organum* appeared in 1620 after a long incubation. In that immortal work the right use of the inductive and deductive methods of reason-

ing was set forth, and the importance of observation and experiment was insisted upon as a means of forming correct premisses, without which all conclusions must be unsound. Yet the old reproach, "Physician, heal thyself," might have been applied to Bacon, for in his last work, *Sylva Sylvarum*, he showed himself as credulous as his predecessors, and he rejected the Copernican theory. He was probably unaware of Harvey's discovery, for he died in 1626, and a comparison of dates shows that Harvey could not owe anything to the *Novum Organum*, yet no better example of the right use of the Baconian methods of reasoning could be produced than the treatise *De Motu Cordis et Sanguinis*.

After discussing the views then generally held as to the functions and action of the heart and the lungs and blood vessels, and showing how untenable they all were, Harvey describes his own investigations. He tells us that for the purposes of this research he had thoroughly dissected more than eighty species of animals—cold- as well as warm-blooded—and that at first in his vivisections he could not follow the sequence of events or understand the meaning of what was happening before his eyes, so that he "was not surprised that Andreas Laurentius should have said that the motion of the heart was as perplexing as the flux and reflux of Euripus had appeared to Aristotle." But "at length and by using greater and daily diligence, having frequent recourse to vivisections, employing a variety of animals for the purpose, and collating numerous observations, I thought that I had attained to the truth." All the world now knows that he did not deceive himself.

Although there seems no reason to doubt that the Fellows of the College of Physicians were convinced by his arguments and demonstrations, it is remarkable how little evidence of their conviction is to be found in contemporary medical literature, or for a good many years afterwards. In the works of Glisson, for instance, the weight of the heavy hand of Galenical authority is everywhere manifest, and nowhere in them do we find evidence that he had understood and accepted the newly found truths. Yet it might have been expected that a physician of the intelligence and originality of the author of the *Tractatus de Rachitide* would have eagerly absorbed and promulgated Harvey's views on the circulation. Sir Thomas Browne—who, it is true, was greater as a euphuist and man of letters than as a physician or natural philosopher—is silent on the subject. Had he understood and accepted Harvey's methods he could not have gravely discussed the question of why a badger has the legs on one side longer than those on the other without verifying his premiss by examining a specimen of that interesting animal, which must have been easily procurable at Norwich in his day. But *non omnia possumus omnes*, and had Browne devoted himself to observation and experiment we might have lost a charming writer without gaining a valuable man of science.

Harvey's later work, *De Generatione Animalium*, while it embodies a mass of accurate observations, could not in the nature of things be so fruitful in results as the earlier one. He had not the instruments which were necessary for the discovery of the ovum and the spermatozoon, and in his ignorance of their very existence he could not even guess at the parts played by them.

Among laymen, Dryden is one who pays a tribute to Harvey, but Cowley's ode is far more worthy of

<sup>1</sup> This and other quotations are from the Sydenham Society's translations of the works, by R. Willis, M.D. London, 1847.

its subject and shows an appreciation of the circumstances which is quite surprising.

"Thus Harvey sought for truth in Truth's own book  
—Creation—which by God himself was writ;  
And wisely thought 'twas fit  
Not to read comments only upon it,  
But on th' original itself to look.  
Methinks in Art's great circle others stand  
Lock'd up together hand in hand:  
Everyone leads as he is led,  
The same bare path they tread,  
A dance like that of Fairies, a fantastic sound,  
With neither change of motion nor of ground.  
Had Harvey to this road confined his wit,  
His noble circle of the blood had been untrodden yet."

The little dark-complexioned physician was truly magnanimous. He wrote: "I would not charge with wilful falsehood any one who was sincerely anxious for truth, nor lay it to any one's door as a crime that he had fallen into error. I avow myself the partisan of truth alone." In him was re-incarnated the spirit which animated Aristotle, and which had long been dormant. He was a high priest of the God-of-things-as-they are, and a forerunner of Hunter and Pasteur and Lister. As Professor Stirling has well said: "For all time he set the method, viz., that of experiment and induction, which has led to all modern progress in physiology." Well may the College which he loved celebrate this tercentenary.

### MILK AS A GROWTH STIMULANT.

A SUMMARY of a report of an investigation on diets for boys during the school age, carried out by Dr. Corry Mann for the Medical Research Council, will be found at page 318. This report may, perhaps, be usefully set beside the results of the investigations on child life in Scotland undertaken by Professors Noël Paton and Leonard Findlay for the Medical Research Council, of which we gave an account a fortnight ago (July 31st, p. 214). Dr. Corry Mann's report has furnished the popular press with a headline because he discovered, among the advantages of adding a pint of milk to a boy's daily diet, that the boy developed more "spirit," and consequently was more often in trouble. The report from Scotland, which finds that maternal efficiency is the only factor manifestly correlated with nutrition in the young child, has not had the same journalistic attraction, but is of not less practical importance. The two reports, however, are not directly comparable, for the Scottish report dealt with children of pre-school years, whereas Dr. Corry Mann's dealt with boys in a boarding-school. Professors Paton and Findlay were concerned mainly with the influence of slum life on the growth and nutrition of children; Dr. Mann with the results of different diets on one class of boy living under well defined conditions. The Scottish investigators concluded that diet is not the main factor in determining the smaller size of the slum child as compared with the rural labourer's child; and they are of opinion that no statistical method can answer the question whether the weight of the child depends upon the diet or whether the diet is determined by the size and habits of the child. They think the suggestion that the consumption of fresh milk is the factor determining the difference in weight between town- and country-bred children is negatived by the fact that in rural miners' families with heavier and larger children even less milk is consumed than in slum families. In fact, Professors Paton and Findlay are led to the conclusion that income, condition of the home, diet,

and maternal occupation and health have little to do with the small size of the slum child. Rather are they of opinion that urban populations differ racially from rural; that smallness is to some extent hereditary; that the smaller town dweller begets smaller children than the larger country dweller; that the difference is becoming accentuated by the decrease of emigration from country to town; and that the question may be asked whether the smaller town race is not really an adaptation to environment. The small machine-tending male, and the small, not too prolific female, requiring little food and little exercise, are better suited to urban surroundings than the big brawny man and the large prolific woman, whose energies are more appropriate for rural surroundings. Professors Paton and Findlay find, in fact, that in the slum child after 18 months of age the inherited growth impulse is sufficiently potent to carry it on to the average size of its parents, and that the average diet of the population must be at least sufficient to supply the material and energy required for growth.

Of Dr. Corry Mann's investigation the Medical Research Council, in its preface, says that its chief value may prove to be that it raises many more questions than those to which it gives a definite answer. At all events, there have been no recorded observations comparable in scope and in experimental validity. The startling results due to the addition of a pint of milk a day to a basic diet which already satisfied the appetite of growing boys, were proved to be due, not to the small increase in the fuel value of the diet, nor to the extra protein in the milk, but to more specific, but unexplained, qualities of milk as a food. The addition of this pint of milk converted an average annual gain of weight of 3.85 lb. into one of 6.98 lb., and an annual average increase of height from 1.84 to 2.63 inches. Were these increases due to vitamins or to some other factors? The results were checked by a comparison of the effects produced by replacing the milk with other substances giving a similar number of calories. Thus a measured quantity of sugar was given, with very poor results, showing that the improvement in the physical condition was not due merely to the addition of calories. With a diet containing more vitamin A provided by watercress there was a definite improvement in weight increment, but not in height, and there was some improvement in the skin (chilblains and roughness) and in the general physical condition, although the increase in the calorie value of the diet was negligible. The addition of casein, which altered considerably the protein quality in the basic diet, produced singularly little effect on nutrition. The only approach to the effects of adding milk to the basic diet occurred when butter was substituted for the milk. The average annual gain in weight was then 6.30 lb., and the average increase in height 2.22 inches. Vegetable margarine, which was deficient in vitamin A, showed an increase in average annual weight increment to 5.21 lb., but the average growth rate remained the same as with the basic diet, 1.84 inches.

Whether these results should add new weight to the "Drink more milk" slogan, or whether it would be well to await the result of further observations, it is not easy to say. It would be interesting to know, for example, whether the boys continue to lengthen and expand at the same rate—all the boys examined were between the ages of 7 and 11—and whether increase of "spirit" continues *pari passu*. And if a race of giants is gradually established, what is to be done with them in view of the hint of Professors

Paton and Findlay to the effect that perhaps small people are more appropriate for modern industry? Agriculture in this country is not sufficiently remunerative to absorb a large number of extra workers; and notwithstanding the healthiness of the families of rural coal-miners, an influx of recruits in the depressed condition of coal-mining can hardly be contemplated. Perhaps at the present moment the best attitude of mind to Dr. Corry Mann's researches is that the questions he raises are not yet ripe for dogmatic statement, and that action should be withheld pending the result of further observations and experiments. This need not alter the view that milk is an excellent food for those who like it.

#### THE BRITISH ASSOCIATION.

SINCE the Prince of Wales, on the evening of August 4th, delivered his presidential address, of which we gave some account last week, the sections of the British Association have met on four days, according to plan, and the members have found recreation in garden parties, evening entertainments, and excursions, and on Sunday they listened to a number of sermons, including one by Sir Oliver Lodge and another by Dean Inge. On Monday afternoon the University conferred the honorary degree of D.Sc. upon eleven distinguished men of science attending the meeting; among them were Dr. Bohr, professor of physics in the University of Copenhagen, the Abbé Breuil, palaeontologist, the Astronomer Royal, Professor H. F. Osborn of Columbia University, New York, and Sir Edward Sharpey-Schafer, professor of physiology in the University of Edinburgh. On the evening of the same day a general meeting, very largely attended, was held to hear Professor Osborn's discourse on discoveries in the Gobi Desert by the American museum expeditions; it was illustrated by lantern slides and cinema films. In a lecture to the Section of Zoology Dr. G. D. Hale Carpenter raised some debatable points as to sleeping sickness. One was whether *T. brucei* of nagana was essentially the same as, and could become, *T. gambiense* of sleeping sickness, and whether *T. rhodesiense*, which caused the more acute disease in man, was derivable from *brucei* or *gambiense* or from both. He thought it possible that the nature of these trypanosomes might depend largely upon the mammalian host rather than upon the species of *Glossina* transmitting them, but that the method of transmission might have much to do with the degree of virulence. Another question was whether insects other than *Glossina* transmit sleeping sickness. Still another was whether big game was a danger; this problem could be solved only by experiment on a volunteer, but there was evidence that prolonged sojourn in an antelope rendered the trypanosome less able to live in man, so that big game might be beneficial rather than harmful. The Section of Physiology suffered somewhat from the fact that the International Physiological Congress was meeting simultaneously in Stockholm, as reported elsewhere. The president of the section, Professor J. B. Leathes, in his address on function and design, sought a definition of life. It was, he said, exhibited only in aqueous systems, containing unstable, perishable combinations of carbon with hydrogen, nitrogen, sulphur, phosphorus, and oxygen, in the presence of certain inorganic ions. The inalienable property such matter exhibited was that these unstable organic combinations were for ever re-forming themselves out of simpler combinations which did not exhibit this property; living material constituted so as to behave in this way appeared to be largely, if not entirely, of a protein nature; this power of self-reformation, spontaneous regeneration, operated not only when living organisms, cells, or com-

munities of cells were growing, or reproducing their kind, but also during their maintenance. Properties and behaviour of cells resulted from those of the material composing them. When a muscle cell contracted there was a reversible rearrangement of its parts, but in other cells, such as connective tissue cells, certain reactions were irreversible. Such cells discharged into their vicinity some material, the chemical constitution of which was usually collagen, in which they became embedded, to form aponeuroses, tendons, and ligaments. After referring to the production of cartilage and bone, he said that the way in which the vertebrate connective tissues took their shape transferred a large share of the developing of the bodily form back into the nervous system, in which was stored machinery that directed and determined the habitual movements and postures. The work of Pavlov had made it clear that by a physiological reaction in the nervous system machinery might come into existence which did not exist before. It was probable, if not proved, that this new machinery was situated in what might be called the growing point of the central nervous system, the cortex of the cerebral hemispheres, the part where all is not cut and dry, where cells retain more of the properties of the developing neuroblast. In the formation of a conditioned reflex two events were made to occur in the cerebral cortex at times uniformly related to one another; one of these events necessarily, from the constitution of the nervous system, resulted in a certain activity of some muscle or gland. After many repetitions of the association of these events it was found that one which previously had never resulted in a particular activity came to have this result as certainly as the other. On Friday the section held a joint session with the Section of Zoology for a discussion on tissue culture; it was opened by Dr. H. M. Carleton, and in the course of it Miss H. B. Fell, Ph.D., said that the method of tissue culture *in vitro* was specially valuable as a means for investigating the capacity of isolated embryonic organs and fragments of organs for self-differentiation. Other discussions in this section were on the relation of vitamin B to "bios"; on the meaning of the symptoms of beri-beri, introduced by Dr. J. C. Drummond; and on reflex posture, to which Dr. F. M. R. Walshe, Sir Charles Sherrington, Mr. D. Denny-Brown, and Professor J. A. Gunn contributed. On August 10th Dr. J. S. Haldane, F.R.S., gave his promised lecture to the section on acclimatization to high altitudes; in the course of it he dealt with the physiological facts elicited by the Mount Everest expeditions, which, he said, were of a striking character. It had been shown that acclimatization sufficient to prevent any symptoms of mountain sickness could be obtained at a height of even 27,000 feet, and probably higher. He proceeded to discuss this observation, which might seem to be in conflict with laboratory experiments. To account for the acclimatization on Mount Everest without the assumption of active secretion of oxygen inwards by the lungs appeared to him to be a hopeless task.

#### MR. CHAMBERLAIN ON THE VOLUNTARY SYSTEM.

AFTER opening a new Ear, Nose, and Throat Hospital in Glasgow last week the Minister of Health made an interesting statement of his views as to the future of the voluntary hospital system. Mr. Chamberlain said that not very long ago those who were interested in voluntary hospitals felt serious anxiety as to their future, and had wondered whether it would be possible for the voluntary system to survive the after-effects of the war. This fear had been due largely to the enormous increase in the maintenance costs following the war, and in particular to the improvement of the conditions under which nurses worked, a reform which had been long overdue. Disaster

had been averted by a grant of about half a million pounds by the Government of the day some five years ago. To-day the position was very considerably improved, although it could not yet be described as entirely satisfactory. Population was still increasing, and during the war it had not been possible to make those extensions of voluntary hospitals which were from time to time necessary. The result was that to-day the needs of the public were far from being adequately met, and further beds were urgently required. The Hospitals Committee had recommended 13,000 extra beds, but if they were got anxieties would be increased, because every new bed meant an increase in the heavy annual cost of maintenance. In an ideal state of society institutional treatment would be available for everyone who needed it. He hoped to advance the solution of the problem by the proposals he had recently made with regard to the reform of the Poor Law. Under them boards of guardians in England and Wales would cease to exist, and their functions would be taken over by local authorities. In England something like 30,000 beds were under the control of boards of guardians, in many cases almost exactly of the same character as those in voluntary hospitals. These beds would come under the control and supervision of the local authorities. The question would arise whether it would be possible to devise a scheme under which municipal and voluntary hospitals could work together in close co-operation. He had not in contemplation, at any rate at the present time, any legislation which would interfere with the working of the voluntary hospital system. One aim should be to establish some central health authority in every district. The area of such a district might well be the local government area or the area of the county council. Such a body as he proposed would have to survey what hospital accommodation was necessary, and to consider the question of duplication, which was a waste of money and effort; it should therefore have the power of veto over extensions of individual institutions. On the other hand, it would naturally be called upon to give assistance to individual institutions, provided they conformed to generally approved lines of policy. To preserve the best features of the voluntary system it would not do to work too much in watertight compartments. A greater amount of co-operation seemed to be the ultimate goal. He believed that any system under which people looked all the time to the State to help them would be disastrous. He believed in self-help, in initiative, and in independence, but, at the same time, he thought that if the country was to get the best out of its resources there must always be someone to see that there was co-ordination.

#### MINER'S PHTHISIS IN SOUTH AFRICA.

DR. W. WATKINS-PITCHFORD is leaving South Africa after some thirty years spent there in pathological, bacteriological, and public health work. After holding several appointments in Natal and the Transvaal, Dr. Watkins-Pitchford became the first director of the South African Institute for Medical Research, Johannesburg. In 1916 the Legislature of the Union established a Miner's Phthisis Medical Bureau to administer the medical sections of the Miner's Phthisis Act, and Dr. Watkins-Pitchford was appointed chairman. We have received a copy of Dr. Watkins-Pitchford's swan-song in the shape of the report of the bureau for the year ending July 31st, 1924. The report is a sufficiently voluminous proof of the energy and activity he has displayed. The bureau consists of whole-time officers responsible directly to the Government. Their work is of great pecuniary importance to the gold-mining industry of the Transvaal, which has to pay compensation to mine workers and their dependants in cases of miner's

phthisis; the expenditure involved is about £800,000 a year. The medical officers undertake an "initial" examination for fitness of all those who wish to work in the mines, and a "periodical" examination of all who are exposed to quartz dust in the mines, every six months of Europeans and every three months of natives; a "benefits" examination of any worker who believes he has contracted miner's phthisis; and *post-mortem* examination, in the interests of the dependants, of all deceased mine workers. The disease, whether it is complicated by tuberculosis or not, is always referred to by the officers of the bureau as "silicosis." It appears that at the initial examination from 42 to 73 per cent. of the candidates for mine work have been rejected in various years, almost entirely for pulmonary defect. As a result of this stringent test, amongst 6,000 Europeans passed since 1916 only seven cases of silicosis have occurred, and only twelve cases of simple tuberculosis. Periodical examinations of 12,000 European working miners showed an incidence of simple tuberculosis of 90 per 100,000, as compared with 321 per 100,000 in 1920. The rate of incidence of simple silicosis, however, has risen from 1,756 to 2,652 per 100,000; 319 fresh cases have occurred in the 12,000 workers during the year under review. But practically all these new cases were amongst men who were working before 1916. The mean duration of employment in the mines before the appearance of signs of the disease—the "average effective period"—has risen from 113 months to 125. It has been found that early retirement from the work does not affect the prognosis of silicosis. Retirement is compulsory for simple tuberculosis and for tuberculosis with silicosis; the rate of incidence for the last mentioned condition has fallen from 800 to 164 per 100,000. The diagnosis of silicosis has been greatly helped by radiography. In 225 out of 541 ex-miners who had been compensated for silicosis before the bureau was formed, no evidence of either silicosis or tuberculosis could be found on examination for a further compensation claim. *Post-mortem* examination of 122 miners showed that silicosis was responsible for death, or contributory to it, in 41 per cent. of the cases. The 178,000 native labourers are not all submitted to examination; but only those who are sent by the mine medical officer as suspected cases of tuberculosis or silicosis. Consequently the rates of incidence of the diseases are not strictly comparable with those amongst Europeans. But there is no doubt that silicosis is comparatively infrequent amongst natives. This is accounted for by the fact that few natives work more than six or nine months at a time, and then have long holidays at their kraals. Dr. Watkins-Pitchford has come to the conclusion, as the result of a special investigation of natives who had worked continuously for longer than five years, that the native is neither less nor more susceptible to silicosis than the European. During this special investigation several cases of simple tuberculosis and tuberculosis with silicosis were discovered which had not been suspected. Dr. Watkins-Pitchford attaches great importance to "this unsuspected reservoir of infection" from carriers, and thinks that they may reasonably be credited with having originated many of the 878 other cases of tuberculosis and of the 438 fresh cases of silicosis which occurred during the year. He advocates the creation of a small but energetic organization for the detection of tuberculosis amongst native recruits and employed labourers. The report contains notes upon cancer of the lung, upon the pathological changes in the lungs which are specific to silicosis, and upon the non-prevalence of syphilis, Bright's disease, and miner's nystagmus. This report of the Miner's Phthisis Medical Bureau shows that Dr. Watkins-Pitchford has indeed deserved well of the country of his adoption.

## A CODE OF MANNERS FOR MOTOR DRIVING.

LORD MONTAGU OF BEAULIEU, who before now has told motor drivers some plain truths, published recently an article in the *Times* on road manners, and a few days afterwards our contemporary published a leading article which began by saying that road manners might be not only bad, but wicked, and even in their milder manifestations bad road manners were inconvenient and a nuisance. As a remedy for dangers as they exist the *Times* wants a slogan so direct and simple that "the wayfaring men [and women], though fools, shall not err therein." We commend to the notice of the *Times* the "offside rule" for the motor driver; it has been adopted by the Automobile Association, and provides a slogan than which nothing can be more direct and simple: "Watch for traffic—horse, motor, or pedestrian—on your right hand." Incidentally a study of this rule will reveal that without some such rule police and magistrates are not in a position to distinguish amid the chaos of conflicting evidence, and so fix the responsibility for accidents with some measure of justice. It is just this fixing of responsibility which will reduce the toll of accidents to those which are really unavoidable. The article by Lord Montagu of Beaulieu raises yet another problem, though the adoption of a code of manners such as he suggests would undoubtedly contribute to solving it. It is well that he notes the uncertainty about the convention of hand signals, for the fewer the signals the better; and that he also calls attention to the bad manners of neglecting to keep to the near side of the road, of blocking the road with stationary cars, of leaving a car directly opposite an entrance, of smoky exhausts, and of glaring headlights in towns where only de-lights are necessary. Of the complaints to which he gives utterance that which perhaps has most medical interest is about the making of unnecessary noise by too frequent sounding of the horn, or by using open exhausts or inefficient silencers. These noises are a growing nuisance, especially at night, and, as Lord Montagu points out, cause suffering not only to the sick, but to all classes of the population who desire to sleep. The use of the horn is a difficult problem for the motorist. The experienced motorist can drive perfectly safely with hardly any sounding of the horn, and at night in the country the use of headlights renders its use almost completely unnecessary. On the other hand, the first cry of every pedestrian who thinks he has missed being run over is usually, "Why didn't you hoot?" For the "cut-out" and the inefficient silencer there is now no excuse whatever. The motor cyclist is the worst offender in this way, and he becomes a danger on the road because the noise of his open exhaust prevents him from hearing the warnings of overtaking vehicles. As magistrates are empowered to impose fines on the owners of vehicles not properly silenced, there should be no difficulty in dealing with this nuisance. At present it continues apparently unchecked, so that the Home Secretary has been impelled to issue a warning to all users of motor cars, and particularly motor cyclists, that he has instructed the police to take active steps to enforce the law relating to the use of silencers. The law is twelve years old, and was last amended four years ago; the Home Secretary described the nuisance as intolerable. The prefect of police in Paris speaks of the intolerable noise made by cars not fitted with silencers, and has called a special meeting of the permanent traffic committee to consider the rules he proposes to make. Lord Montagu says that "the motoring organizations are trying all the time to inculcate good manners and due consideration for others by publishing rules to be observed." One of the questions raised by his article seems to be whether the time has not arrived for these organizations to meet together and discuss the whole subject of the courtesies of

the road. It is by no means certain that the various bodies are at present so fully agreed on these courtesies that they could be embodied in a code sufficiently simple and not too lengthy. But without such a code driving is bound to be unnecessarily dangerous to drivers and pedestrians, more and more unpleasant, at least to residents along arterial roads, and increasingly chaotic.

## THE SCIENCE OF GENETICS.

SOME months ago the members of the Dundee Branch succeeded in persuading Dr. F. A. E. Crew, director of the Animal Breeding Research Department at Edinburgh, to give them a British Medical Association Lecture on the mechanism of inheritance, and we are now able to present it to a larger audience, some of whom may find it stimulating holiday reading. A new department of biological science, with its own body of observations and theories and a special terminology, has sprung up since those engaged in its prosecution believe, with Dr. Crew, that the medical man will do well to make himself acquainted with its principles, since they will help him to a better understanding of some of his many and varied problems. The rapid advance of genetics may be dated from the early years of this century, when, as Professor J. B. Leathes said in concluding his address at Oxford, the forgotten experiments of Mendel came to the surface again, and found corroboration in the cytological studies that from about the same time had pursued their slow obstructed way in the attempt to elucidate the changes in the nucleus of maturing germ cells. He went on to express the view that to-day the study of genetics and of the topographical anatomy of the chromosomes, with its groupings and crossings-over, seems to call out for chemical assistance. Those who wish to pursue one aspect of the matter further may consult the small volume *An Introduction to Experimental Embryology*, by Mr. G. R. de Beer, Jenkinson Memorial lecturer in comparative and experimental embryology at Oxford. Perhaps because the units with which they deal are beyond the powers of the microscope, exponents of the new science, like Dr. Crew, consider it necessary to be extremely precise and logical in their expositions; and though Mr. de Beer does not suffer to so large an extent from this disadvantage he also is severely logical in his explanations, so much so that the book is by no means easy reading. It is full of facts as well as theories, and neither by his manner of using the new terms nor by his literary style does Mr. de Beer do much to conciliate his readers. Nevertheless the book is well constructed and extremely informing.

## AN ESSAY ON THE UNKNOWNABLE.

THE Dean of St. Paul's, invited to deliver the Fison Memorial Lecture for 1926 at Guy's Hospital Medical School, bravely set forth to explain his views on *Science and Ultimate Truth*, and the lecture has been published in pamphlet form.<sup>2</sup> It is extremely interesting, even if at times the ideas and the language which clothes them are not too easy to understand. The Dean, like every human being who takes the trouble to think, has a philosophy of his own; and in his lecture he strives to explain how his philosophy differs from that of Hume, Kant, and Hegel, no less than from materialism, epistemology, positivism, agnosticism, and pluralism. It would appear that he accepts the existence of a Supreme Being, independent of the universe in the sense that

<sup>1</sup> *An Introduction to Experimental Embryology*, by G. R. de Beer, M.A., B.Sc., F.L.S. Oxford: The Clarendon Press, 1926. (Crown 8vo, pp. 148, 7s. 6d. net.)  
<sup>2</sup> *Science and Ultimate Truth*, London and New York: Longmans, Green and Co. 1926. (5½ x 8, pp. 32. Paper cover, 1s. net; cloth, 2s. net.)

Shakespeare was independent of his plays. But the plays are the necessary expression of the mind and character of Shakespeare. We gather that, similarly, he holds the universe to be the necessary expression of the mind and character of the Supreme Being, though we know nothing of the motives of creation. The world is a solid fact, says the Dean, which we have to accept, not to account for. Although the innermost nature of the Supreme Being is unknown to us, He has revealed Himself under the three attributes of goodness, truth, and beauty. These are eternal and ultimate values, and not inactive thoughts. The whole duty of man and the path by which he can claim his status in the eternal world is in the apprehension of these eternal values, and in earnestly striving to co-operate with the Divine will in actualizing them. The values are three paths up the hill of the Lord, which may be supposed to unite at the top. And three specialists, apparently, lead men up the paths—the saint, the poet, and the man of science. At present religion, science, and art are jealous of one another, because each claims, in a sense, to cover the whole field—that is, to interpret all experience from its own point of view. Philosophy tries to mediate between them, and the task has so far been beyond its powers. But the eternal values are not entirely separate from each other; they are, in Dean Inge's view, a triple star, the attributes under which the one Supreme Being has revealed to us His nature and His will. The Dean's most arresting statement is, perhaps, that "the world is a solid fact, which we have to accept, not to account for." The facts of the world, and some of the facts of the universe, can be dealt with by man's intelligence. The unfortunate thing about philosophy is that it is bound to lead to realms which are beyond man's comprehension. It may be that the only attitude of mind towards the nature of those realms that is consistent with man's shortcomings is recognition that the finite cannot comprehend the infinite. And perhaps the man of science, as he slowly plods his way to such knowledge as is within his powers, may sometimes ask himself, "What is truth?" Whether the saint and the poet should also ask themselves "What is goodness?" or "What is beauty?" is not for us to say.

#### RESEARCH DEFENCE SOCIETY.

THE *Journal of the Research Defence Society* for July, in addition to an obituary notice of its founder, Mr. Stephen Paget, illustrated by an excellent portrait, and a report of the annual general meeting, of which we gave an account on July 3rd (p. 27), contains an article by Mr. Leslie R. Aldous of the League of Nations Union, entitled "Fighting disease internationally." Mr. Aldous sketches the work already done by the Health Organization of the League of Nations. In the early days its energies were occupied by epidemics of typhus and typhoid in Eastern Europe; and a line of hospitals, and of disinfecting and quarantine stations, was established along the whole Polish frontier. Since this emergency action the Health Organization has been dealing with sleeping sickness, tuberculosis in South African mines, cancer researches, and malaria. Its Malaria Commission is concerned at the inadequate supply of quinine available, and is carrying out experiments with substitutes. The League of Nations has also supplied health advisers to certain countries, such as Albania and Persia. The president of the Research Defence Society is Lord Lamington, and its chairman is Lord Knutsford. Sir David Ferrier and Lady Horsley are the honorary treasurers of the society, Dr. G. P. Crowden is honorary secretary, and Dr. Alfred Salter, M.P., its parliamentary honorary secretary. The Research Defence Society's address is 11, Chandos Street, London, W.1.

#### THE PROFESSIONAL CLASSES AID COUNCIL.

THE Professional Classes Aid Council has now completed five years of work since it was reconstituted from the Professional Classes War Relief Council formed in October, 1914. The report of the council for 1925-26 shows that it does much useful work upon rather a slender income; and this year, for the first time since 1921, there is a slight excess of income over expenditure. The council wisely devotes much of its effort to assisting in the education of the children of applicants; but help is also given in illness, towards maintenance, and for bridging a period before the recipient is in a position to be independent of further help. The necessity for inquiry into the good faith of applicants seems to be fully recognized; and the council would appear to have established satisfactory relations with the numerous professional societies which are represented on it. Existing medical charities probably render it unnecessary for any large number of members of the medical profession to apply for relief. The British Medical Association is represented on the council by Mr. Bishop Harman.

#### THE HALF-YEARLY INDEXES.

THE usual half-yearly indexes to the *JOURNAL* and to the *SUPPLEMENT* and *ERRATA* have been printed; they will, however, not be issued with all copies of the *JOURNAL*, but only to those readers who ask for them. Any member or subscriber who desires to have one or all of the indexes can obtain what he wants, post free, by sending a postcard notifying his desire to the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1. Those wishing to receive the indexes regularly as published should intimate this desire.

AN Order of Council has been issued altering the composition of the Committee of Privy Council for Medical Research, the ministerial body under which the Medical Research Council conducts its work. The Committee originally consisted of the Lord President of the Council, the Minister of Health (England and Wales), the Secretary for Scotland, and the Chief Secretary for Ireland, but the last named office has become obsolete as a result of the changes in the government of Ireland. In view of this vacancy, and of the increasing relation of the Medical Research Council to research work in overseas parts of the empire and in industrial medicine, the Secretaries of State for Home Affairs, for Dominion Affairs, and for the Colonies have now been added to the Committee.

THE first number of the *Journal of Neurology and Psychopathology* to be issued by the British Medical Association (that for July) has been published. The *Journal* continues to be edited by Dr. Kinnier Wilson, with the assistance of an Editorial Committee of psychologists. It is published quarterly. The annual subscription, which should be sent to the Financial Secretary and Business Manager of the British Medical Association, Tavistock Square, London, W.C.1, is 30s. The price of single numbers is 8s. 6d. post free. The new number contains an analysis of the affective symptomatology of disseminated sclerosis founded on 100 cases, by Dr. S. S. Cottrell of Richmond, Virginia, and Dr. Kinnier Wilson; the first part of a lecture on the psychology of character, by Dr. William Brown; a report of a case of recovery from spontaneous subarachnoid haemorrhage, by Dr. Parkes Weber and Dr. Bode, from the German Hospital, London; an editorial article on perspective in psychiatry; and a set of abstracts.

## THE INTERNATIONAL PHYSIOLOGICAL CONGRESS AT STOCKHOLM.

(From L. E. BAYLISS, a Member of the British Physiological Society.)

THE twelfth International Physiological Congress, which began on Tuesday, August 3rd, at Stockholm, is undoubtedly one of the largest and most truly international that has ever been held, since there are 600 members, from absolutely every country in Europe, from China and Japan, and from the United States and Canada. We are having presented to us 272 communications and 40 demonstrations, with the result that it is quite impossible to hear more than a very small fraction of them, although it is possible to get some idea of a certain number more with the help of the summaries printed in the *Skandinavisches Archiv für Physiologie*.

*Address of Welcome.*

The congress opened with an address of welcome on behalf of the Swedish universities by the Archbishop of Sweden, who made an appeal, in excellent English, for the purity of science and the necessity for the pursuit of knowledge as an end in itself, without thoughts of practical utility. The Governor of the City of Stockholm then welcomed (in French) the congress to the city and placed its resources at our disposal, and the principal of the Caroline Institute expressed (in German) the delight with which his institute received us in Stockholm.

*The Mechanisms of Biological Oxidation.*

After a short address by the president, Professor J. E. Johansson, in which he deplored the deaths of so many famous physiologists in the last three years, Professor Sir F. Gowland Hopkins gave a lecture on the mechanisms of biological oxidation. Opening with a defence of the modern tendency of biochemical laboratories to separate themselves from the physiological, and though emphasizing the necessity for close co-operation, he advocated the development of institutes of general biochemistry, which would not be tied down to the study of animal problems, but would deal also with those of plants and micro-organisms. These introductory remarks were well justified by the subsequent more technical statement, in which much of the experimental evidence that has led to the modern conception of biological oxidations has been obtained in the lecturer's own laboratory at Cambridge.

In order to account for the fact that in living tissues substances are oxidized quite readily, which can only be dealt with *in vitro* by means of powerful chemical reagents, Warburg has supposed that the molecules of oxygen are activated probably by traces of iron. Wieland, on the other hand, regards the activation of the substance to be oxidized as more important, or, more exactly, the activation of a constituent hydrogen atom, so that it can combine readily with a "hydrogen acceptor"; this may, of course, be molecular oxygen, or in its absence some easily reducible organic compound.

After presenting the evidence in favour of these two views in a beautifully critical manner, the lecturer went on to the most recent developments of the subject, which take into consideration the possible effects of the electrical fields at charged surfaces, which may be quite large, the conceptions of oxidation and reduction as essentially a transfer of electrons from the substance oxidized to the substance reduced, and described the two forms of "hydrogen transporter," whose function it is to act as

intermediaries in the transport of the activated hydrogen to the final hydrogen acceptor, which in the case of normal living cells is oxygen. In plants the chief hydrogen transporters are polyphenols, and in animals the organic sulphides, notably a dipeptide of glutamic acid and cysteine—"glutathione."

Finally, Professor Hopkins reached the conclusion that, of the two views, Wieland's was the more important, although it would be absurd to suppose that activation of oxygen never occurred in the living cell—there is too much evidence in favour of it—but the subject is complicated by the fact that not only does iron activate molecular oxygen, but it can also catalyse the transport of activated hydrogen by glutathione.

*The Sections.*

The sessions of the congress began in the afternoon, taking place in four sections simultaneously, each devoted, more or less, to one branch of physiology; they are to continue every morning and afternoon till Friday, August 6th. So far the work which has been reported here that will probably have the most interest to those engaged in medicine have been the experiments of Magnus and his fellow workers in Utrecht on the function of the cerebellum in the balancing reflexes; the measurement of the heat produced by a nerve on stimulation, by A. V. Hill and R. W. Gerard of London; and the recording of the electrical response of a nerve stimulated through its own end-organ—for example, touch and pain—by Adrian of Cambridge. Kato, from Tokio, has brought forward his theory of the decrementless conduction in narcotized nerve, and Girard and Peyré of Paris have defended their theory that by injecting caesium eosinate into an animal it is protected from subsequent injections of substances which would normally produce shock. The modern conception of the spleen as a reservoir of blood corpuscles, to be discharged into the blood as soon as there is any tendency towards asphyxia in the tissues, has been demonstrated by Barcroft of Cambridge on a dog brought over specially; this conception has been confirmed by Scheunert and Krzywanek of Leipzig. Recent observations on the heart occupied the whole of one section on Tuesday afternoon (August 3rd), notably the work of Anrep and co-workers of London on the coronary circulation, and Loewi of Graz on the production of an inhibiting substance, believed to be a complicated ester, by stimulation of the vagus.

*Distractions.*

On Tuesday evening the whole congress made an excursion to Skansen, which is an open-air museum and zoological gardens on a rocky height overlooking Stockholm. Here are to be seen replicas of old Swedish houses and Lapland huts, and here were arranged folk-dancing and folk-singing. Refreshments were obtained in a restaurant built and decorated as an ancient Swedish house, and were served by attendants in old-fashioned costumes.

This evening (Wednesday) the city of Stockholm gives a banquet in the city hall, which, together with the concert hall, in which the opening meeting was held, is a very fine example of modern Swedish architecture, undoubtedly some of the finest in the world.

Stockholm, August 4th.

## DIET FOR SCHOOLBOYS.

BETWEEN 1921 and 1925 Dr. H. C. Corry Mann conducted an investigation into diets for boys, and his report has been published by the Medical Research Council.<sup>1</sup>

Dr. Mann's observations were made at an institution near London, where some six hundred boys are housed under the "villa" system; there are thirty to thirty-five boys in each house, and the rate of sickness is low. During four

years records were made by weighing sample rations daily for each of the three meals, thus obtaining minimum and maximum helpings for smaller and larger boys. This was called the basic diet; and it supplied from 1,679 to 2,154 calories daily—37.3 calories per lb. of body weight for a boy of 45 lb., and 35.9 calories per lb. of body weight for a boy of 60 lb. For the purposes of investigation boys of southern English stock were selected, excluding all trace of colour or of foreign, Latin, Scandinavian, or Hebrew type. Their ages varied from 7 to 11 years, their

<sup>1</sup> Medical Research Council, Special Report Series No. 105. *Diets for Boys during the School Age*. By H. C. Corry Mann, O.B.E., M.D. H.M. Stationery Office, London, Manchester, Cardiff, Edinburgh, Belfast; or through any bookseller. Price 2s. 6d. net.

weights from 45 to 60 lb. Any disabilities observed in the boys were due to deficiency of weight and height for age, and not to infective disease. An equal number of the same age and rating was assigned to each of the houses in which the investigations were carried out. After a preliminary period of observation, the group of boys in House I, receiving only the basic diet, were kept under strict observation, and records made of their general health, gain in weight, and increase in height. In House II each boy received in addition to the basic diet one pint of fresh cow's milk daily. In House III a daily ration of 3 oz. of castor sugar was added to the basic diet; in House IV  $1\frac{1}{2}$  oz. of butter; in Houses V and VI  $1\frac{1}{2}$  to  $3\frac{1}{4}$  oz. of watercress; in House VII  $3\frac{1}{4}$  oz. of casein, and in House VIII the same amount of vegetable margarine. The object of these researches was to discover whether an increase of height and weight could be best obtained by giving the boys merely more calories by means of the sugar ration, by adding fat alone, by giving fat with vitamin, or by adding vitamin alone. The casein ration was chosen for the purpose of discovering whether improvement in the biological value of the protein might not be more necessary than any other change in the basic diet.

The basic diet in use at the institution contained only a relatively small amount of fat. In a diet of good average quality the fat accounts for 30 to 35 calories. In the basic diet it accounted for only 18. The protein was adequate for growth, although only 25 per cent. instead of the normal 35 to 45 per cent. was from animal sources. The carbohydrates, consequently, were in excess and accounted for 68 per cent. of the calories of the basic diet, as compared with 50 per cent. in a good average diet. The calorie value of the basic diet appeared adequate, though an improvement in nutrition would probably occur if the balance and quality were altered. Boys on the basic diet grew an average of 1.84 inches a year, and gained 3.85 lb., as compared with an average increment of 5.5 lb. observed in healthy school children of the industrial class. The boys who received in addition the cow's milk ration gained an average of 6.98 lb. and grew an average of 2.63 inches. With sugar the average gain was 4.93 lb. per boy and 1.84 inches; with butter 6.30 lb. and 2.22 inches; with margarine 5.21 lb. and 1.84 inches; with casein 4.01 lb. and 1.76 inches; with watercress 5.42 lb. and 1.70 inches. Incidentally it was found that on all diets there was invariably rather more growth during summer than during winter, and usually more gain in weight. A further point of interest is that the boys who got the extra ration of milk not only did best in weight and height but were "obviously more fit than those of the other groups." There was a general absence of illness. The boys lost the marked tendency to chilblains in the winter, and a roughness of the skin and tendency to pot-belly which were common among those eating only the basic diet. They became far more high-spirited and irrepressible, and for this reason were often in trouble, but there was no indication of greater proficiency at school.

The conclusion reached in the report is that in an institution where there was no deficiency of fresh air or sunshine an immediate improvement in physique followed an alteration in the quality of a diet which was adequate from a physiological standpoint. This improvement was most marked when fresh cow's milk, recently pasteurized, formed the additional item of food; and the improvement, both in weight and height increments, was not temporary but was maintained over a period of one, two, or three years. In an appendix the findings are confirmed statistically by Dr. Major Greenwood and Miss G. M. Newbold, who say:

"**Weight.**—On the whole the milk and butter groups both show definite excess increases in weight over the basic group, and of about the same order, but slightly higher for the milk group. Summer shows a definite increase over winter; this is greater in the milk and butter groups than in the basic, and is of about the same order (slightly less) as that of the milk and butter over the basic group.

"**Height.**—On the whole the milk group shows a definite excess growth in height over the basic, and very slightly greater in summer than in winter. The excess growth of the butter group over the basic is not significant, and is only about one-third that of the milk group. Summer growth shows a definite increase over winter, very little lower than that of the milk group over the basic, and on the whole greater in the milk group than in the butter or basic."

## OPERATIONS FOR CANCER.

We announced a fortnight ago that the Ministry of Health has issued two reports on cancer—the one (No. 33) by Dr. Major Greenwood, on the natural duration of cancer, and the other (No. 34), on the late results of operation for cancer of the breast.<sup>1</sup>

### LATE RESULTS OF OPERATION FOR CANCER OF THE BREAST.

The report on the late results of operation for cancer of the breast is based on 357 cases in which operations for cancer of the breast were performed in Leeds at the General Infirmary and the Hospital for Women and Children, during the years 1910-13 and 1919-21. The after-histories are unusually complete, ten cases only being untraceable, and in all but a few the cause of death was accurately obtained. The diagnosis of the primary growth was in all cases confirmed by microscopical examination.

The cases are grouped, according to the stage of the disease at the time of operation, under three headings—namely, Class I, the breast alone affected; Class II, the axillary glands also implicated; and Class III, other structures involved. In some instances, naturally, it was impossible to decide into which class a case should be placed, but this has not invalidated the final results of the investigation, which was directed to three main points: (a) the average duration of the disease prior to operation; (b) the results of operation as found at three, five, and ten years afterwards; and (c) survivorship, or the number of cases surviving in successive years after operation, compared with survivorship in healthy persons.

#### A. Average Duration of the Disease Prior to Operation.

The average duration of the disease prior to operation is exhibited in the following two tables.

Mean Period for Alleged Duration of Five Years and Under.

|                  | Years. | Months. | Weeks. | Days. | Cases. |
|------------------|--------|---------|--------|-------|--------|
| Class I ... ..   | —      | 6       | 3      | 2     | 82     |
| Class II ... ..  | —      | 9       | 2      | 0     | 110    |
| Class III ... .. | 1      | 2       | 2      | 3     | 91     |

Mean Period.

|                      | Years. | Months. | Weeks. | Days. | Cases. |
|----------------------|--------|---------|--------|-------|--------|
| All cases ... ..     | 1      | 0       | 2      | 4     | 321    |
| Under five years ... | —      | 8       | 3      | 4     | 310    |
| Under three years    | —      | 7       | 1      | 6     | 295    |

In a few cases the alleged duration was as much as ten, fifteen, and even twenty years, but the above calculation was restricted to five years and under, because it seemed doubtful whether the growths could have been malignant during the whole of more prolonged periods. The figures show a sensible difference in the alleged durations in the several classes, indicating, as might have been expected, a definite relationship between the duration of the tumour and the stage of the disease.

#### B. The Results of Operation after Three, Five, and Ten Years.

In tabulating the late results of operation all the cases were available for the three-year period; all except those operated upon in 1921 for the five-year period; and all the 1910-13 cases for the ten-year period. The results

<sup>1</sup> Ministry of Health. Reports on Public Health and Medical Subjects. No. 33: *The Natural Duration of Cancer*, by Dr. Major Greenwood; price 9d. No. 34: *The Late Results of Operation for Cancer of the Breast (Leeds)*, price 6d. H.M. Stationery Office, London, Manchester, Cardiff, and Edinburgh.

appear in the following three tables, which are abbreviated from those in the report.

Table showing Fate of 357 Patients Operated on for Cancer of the Breast, at Three Years after Operation (1910-13 and 1919-21).

|   | Cl. I. | Cl. II. | Cl. III. | Unclassed. | Totals. |
|---|--------|---------|----------|------------|---------|
| Cases ... ..                            | 87     | 124     | 100      | 46         | 357     |
| Alive at three years...                 | 78     | 45      | 28       | 23         | 174     |
| Died from other causes ...              | 4      | 6       | 10       | 5          | 25      |
| Died within three years after operation | 5      | 73      | 62       | 18         | 158     |

Percentage alive after deducting deaths from other causes: Class I, 94.0; Class II, 33.1; Class III, 31.1; unclassified, 56.1; all classes, 52.6.

Table showing Fate of 286 Patients Operated on for Cancer of the Breast at Five Years after Operation (1910-13 and 1919-20 inclusive).

|  | Cl. I. | Cl. II. | Cl. III. | Unclassed. | Totals. |
|--|--------|---------|----------|------------|---------|
| Cases ... ..                           | 74     | 97      | 74       | 41         | 286     |
| Alive at five years ... ..             | 63     | 18      | 10       | 11         | 102     |
| Died from other causes ...             | 5      | 7       | 8        | 5          | 25      |
| Died within five years after operation | 6      | 72      | 56       | 25         | 159     |

Percentage alive after deducting deaths from other causes: Class I, 91.3; Class II, 20.0; Class III, 15.1; unclassified, 30.6; all classes, 39.1.

Table showing Fate of 171 Patients Operated on for Cancer of the Breast, at Ten Years after Operation (1910-13).

|  | Cl. I. | Cl. II. | Cl. III. | Unclassed. | Totals. |
|--|--------|---------|----------|------------|---------|
| Cases ... ..                                 | 49     | 58      | 40       | 24         | 171     |
| Alive at ten years ... ..                    | 35     | 3       | 2        | 4          | 44      |
| Died from other causes ...                   | 9      | 6       | 4        | 6          | 25      |
| Died within ten years after operation ... .. | 5      | 49      | 34       | 14         | 102     |

Percentage alive after deducting deaths from other causes: Class I, 87.5; Class II, 5.8; Class III, 5.5; unclassified, 22.2; all classes, 30.1.

A comparison of these three tables shows that the percentage of survivors in Class I (in which the disease had not extended beyond the mammary gland at the time of operation) is not only higher than in any other class, but that, if allowance is made for deaths from causes other than cancer, it remains almost constant up to the end of the ten-year period, the figures being 94 per cent., 91.3 per cent., and 87.5 per cent. The unabbreviated tables in Major Greenwood's report also show that a considerable percentage of the more advanced cases survive three years after operation, a smaller number survive five years, but only an occasional one survives up to ten years.

#### C. Survivorship.

The object here was to ascertain the number of survivors in the several categories, in successive years after the operation, and to compare this with the normal decrease in an equal number of healthy subjects. The chief interest centres round Class I. It is shown that the survivors of this class ten years after operation number only 14 per cent. below the normal average figure for healthy people. "It is," the report remarks, "impossible to regard this result without feelings of the greatest satisfaction."

#### THE NATURAL DURATION OF CANCER.

Dr. Major Greenwood's report (No. 33), on the natural duration of cancer, is partly theoretical in its aim. In discussing the relative advantages which different methods of operation confer on patients, it is obviously desirable that there should be a clear understanding as to the terms in which the "advantage" is to be expressed. Some mathematical formula which would serve as a standard of comparison is what seems to be required, and in Dr. Greenwood's opinion three conditions should be taken into account in the construction of such a formula—namely:

(a) the average duration of the life of a healthy person of the same age as the patient; (b) the average duration of the life of a patient untreated; and (c) the average duration of the life of a patient operated upon. With these data given, the following procedure might be followed, taking a purely imaginary case for illustration: If the average duration of life in health (a) is eighteen years and that of the untreated patient (b) only three years, the disease reduces the expectation of life to three-eighths of the normal; if now we find the average duration of life in the operated patient (c) to be nine years, his expectation of life has evidently been increased six years by the operation—that is to say, the advantage gained is six-eighths of the average duration of life in the healthy. The advantage is expressed by the formula

$$A = \frac{c-b}{a}. \text{ It has to be remarked, however, that since the}$$

normal expectation of life diminishes with age, the denominator in the above formula would be very small in an old patient and the calculated advantage would be correspondingly large, although, counted in years instead of ratios, the advantage would not in reality be greater than in a young patient. In short, the advantage would appear to increase with age, and Dr. Major Greenwood notes that this would need to be borne in mind. In order, further, that the formula should be consistent, it is necessary that the other two averages should not be materially affected by differences of age; according to the report they are not, there being no significant relation between age at onset and duration, if the data may be considered numerous enough to establish the point.

With regard to the three averages referred to above, the first (a) is known with considerable accuracy, the third (c) is known to a rough approximation in certain forms of cancer only; for the "natural" duration of life of untreated cancer patients (b) we have rather more information, and one object of the report was to collect it. The data analysed are from several hospitals, and include 4,238 cases relating to seven primary sites—namely, the tongue, breast, uterus, rectum, oesophagus, larynx, and stomach. The two longest series are those of Drs. Lazarus-Barlow and Leeming and of Dr. Wyard, and the conclusions reached confirm the conclusions of those authors in all important points. The average duration for all ages, of cancer of the above-named organs, when untreated, is exhibited in the following list; where more than one figure is given opposite the same organ the figures are from separate series of cases.

|                                      |                                  |
|--------------------------------------|----------------------------------|
| Breast .....                         | 39.8; 39.57; 32.78; 36.54 months |
| Stomach .....                        | 17.08 "                          |
| Rectum (females) .....               | 27.14; 25.71 "                   |
| " (males and females) .....          | 28.65; 25.46 "                   |
| " (males) .....                      | 21.42 "                          |
| Cervix uteri .....                   | 22.72; 18.76; 20.12; 15.35 "     |
| Uterus and cervix .....              | 18.22 "                          |
| Tongue and mouth (males) .....       | 16.49; 15.25; 16.94 "            |
| Oesophagus (males and females) ..... | 11.35 "                          |
| Larynx (males and females) .....     | 14.03 "                          |

#### THE MIDWIVES AND MATERNITY HOMES ACT.

THE Midwives and Maternity Homes Act (1926) received the Royal Assent on August 4th. Part I of the Act comes into force at once, and Part II, referring to the registration of maternity homes, on January 1st next.

##### Practice of Midwifery.

The Act prohibits the attendance by a male person or by a woman not certified under the Act upon a woman in childbirth unless under the direction and personal supervision of a duly qualified medical practitioner; but this provision is not to apply to a person who, while undergoing training with a view to becoming a duly qualified medical practitioner or a certified midwife, attends a woman in childbirth as part of a course of practical instruction in midwifery recognized by the General Medical Council or by the Central Midwives Board. The next clause provides that where a midwife has been suspended from practice in order to prevent the spread of infection she shall, if not herself in default, be entitled to compensation from the local supervising authority.

Subject to the sanction of the Minister of Health, local supervising authorities may make arrangements with pregnant women in their area for the payment by such women to the authority, by instalments or not, of sums to cover any liability which the authority may incur under Section 14 of the Midwives Act, 1918,

in respect of fees payable to medical practitioners who may be called in by midwives.

The Central Midwives Board is to divide the roll of midwives into two parts—one, of practising midwives, to be published yearly, and the other at not more than five-yearly intervals. The Board is empowered to make rules as to the wearing of badges by certified midwives.

#### Maternity Homes.

Part II of the Act deals with the registration of maternity homes. After January 1st, 1927, any person carrying on an unlicensed maternity home will be liable to a fine up to £50, or, for a second offence, to three months' imprisonment. "Maternity home" is defined as any premises used, or intended to be used, for the reception of pregnant women or of women immediately after childbirth, but does not include any hospital or other premises maintained or controlled by a Government department or local authority, or by any body constituted by special Act of Parliament or incorporated by Royal Charter. A local supervising authority may grant exemption from registration in respect of any hospital or other premises for the conduct of which a duly qualified medical practitioner resident therein is responsible, or any hospital or institution not carried on for profit and not used mainly as a maternity home. A local supervising authority may at any time withdraw such an exemption. The local authority may refuse to register an application if the applicant or any employee is not a fit person to carry on or to be employed at a maternity home, or if the premises are unfit, or are used for improper or undesirable purposes. It is not now necessary to obtain a licence for the establishment of a lying-in hospital in accordance with the provisions of the Lying-in Hospitals Act, 1773. The new Act does not affect the provisions of local Acts already giving municipalities power over maternity homes. Opportunity is given for appeals against a refusal to license. Authorized inspectors may at all reasonable times enter homes which they have fit cause to believe are used as maternity homes. The certificate of registration must be displayed conspicuously in each home, and the local supervising authority may make by-laws with regard to the records of patients received, children born, and of children removed otherwise than to the custody of parent, guardian, or relative. By-laws may also be made about the notification of any death in a maternity home and of its cause.

The local supervising authority remains as under the previous Midwives Act.

## England and Wales.

#### CLASSIFICATION OF FEEBLE-MINDED OFFENDERS.

The Mental Hospitals Committee of the London County Council has raised objections to certain wider definitions of mental defect recommended by the departmental committee appointed by the Home Secretary in 1924 to consider the question of sexual offences against young persons.<sup>1</sup> The effect of these definitions, in the Mental Hospitals Committee's opinion, would be to make it unnecessary, in order to find defect within the meaning of the Mental Deficiency Act, to prove more than an existing condition of mental enfeeblement. In this way every case of mental degeneration in which the conduct showed the need for care, supervision, and control would be brought, along with every case of congenital defect, within the scope of the Act. The Lunacy Acts and the Mental Deficiency Act would in that event overlap, for in practice it would be found that under both Acts the real standard for decision would be whether a person acted with reasonable regard to his environment. The question of whether a given case should be dealt with as one of lunacy or of mental defect would probably resolve itself into one of institutional accommodation. This, in the view of the Mental Hospitals Committee, is not desirable, nor is it desirable to run the risk of getting together into one institution cases of definite mental degeneration or disease and cases of congenital mental insufficiency. The committee believes that the Government desires the definitions of defect in the Mental Deficiency Act to be somewhat widened in scope by the omission of the awkward limitation imposed by the words "birth or early age," and the substitution of some form of words which would suggest arrest of development. The committee would not object to this, but it believes that the real motive behind the desire for the speedy amendment of the definitions in the Act is to enable more cases suffering from the sequelae of encephalitis lethargica to be dealt with in institutions under the Mental Deficiency Act. This might have some advantages, but it would also give rise to difficulties. The

committee raises no objection to another recommendation of the departmental committee, that after the conviction of a person, but before sentence, the bench shall remand for medical examination and report cases in which mental disease, disorder, or defect is suspected; this might add somewhat to the work of the medical officers, but not greatly. With regard to the recommendation that all courts shall make arrangements for the services of a mental expert, the committee points out that so far as London is concerned the courts of criminal jurisdiction have an arrangement similar to that which the departmental committee proposes. If an offender appears to be mentally defective one of the Council's certifying medical officers examines him, and should the case prove to be one of defect the Council advises the court as to the institution to which the case might be sent. The committee suggests that this arrangement works better than would one whereby the courts were advised by a specially appointed mental expert, whose judgement might not coincide with that of the Council's advisers, and who could not in any event give the court information as to what the Council was prepared to do with the case. Another recommendation of the departmental committee, for the prolonged detention of habitual offenders, raises a matter of principle. The Mental Hospitals Committee thinks that if there are numbers of defectives who are habitual practitioners of public indecency, and not merely a few who attract attention because of the flagrancy of the offence, it would be better to get special legislation providing for their indeterminate detention than to extend the scope of the Mental Deficiency Act.

#### CANCER CAMPAIGN IN YORKSHIRE.

At a meeting of the Yorkshire Council of the British Empire Cancer Campaign, on July 26th, at Leeds, under the presidency of Sir Berkeley Moynihan, it was announced that £100,520 had already been raised in the county. Arrangements were being made for dietetic research in relation to cancer to be conducted at the University of Sheffield, under the direction of Professor Mellanby, at an estimated cost of about £10,000, for which the council would be responsible. Professor Jamieson, reporting on the progress in the development of the Research Laboratory in Leeds, said that two houses and shops, formerly occupied by the Leeds Tuberculosis Committee, had been acquired on a five years' lease, and would be converted for use as a temporary research laboratory, which it was hoped would be able to start work on October 1st. The sum of £1,000 was voted for the equipment of this laboratory, which will be replaced eventually by a new building, towards which Sir Algernon Firth has given £20,000. In the districts of Halifax, Huddersfield, and Keighley the appeal is about to be closed; in each case at least three times the money originally asked for has been received. The inaugural meetings of the Campaign in Hull and Rotherham were very successful, and a substantial increase to the fund appears to be probable, though the continued coal strike has seriously hampered the appeal in some towns in Yorkshire.

#### BRISTOL CRIPPLED CHILDREN.

Crippled children in the city of Bristol are looked after mainly by the Orthopaedic Hospital, the Royal Hospital for Women and Children, and by the Bristol Cripple Children's Society. This society is a purely local organization founded four years ago for the care of crippled children of all descriptions. It arranges for the admission of patients to an orthopaedic hospital in Bristol or elsewhere, pays all hospital and convalescent home fees, and provides any necessary appliances. The society also does much valuable after-care work. The Bristol Orthopaedic Hospital and Home for Crippled Children is a considerably older institution; it contains forty beds for children whose ages range from 3 weeks to 14 years. It is situated on high ground close to the Durdham Downs, about one mile from the centre of the city. A large proportion of its patients are tuberculous. It has no out-patient department, but patients are admitted either from the Royal Infirmary, the General Hospital, or by direct recommendation of doctors

<sup>1</sup> BRITISH MEDICAL JOURNAL, January 16th, 1926, p. 112.

practising in the Bristol area, or, finally, through the intermediary of some benevolent society. A part of the Orthopaedic Hospital is equipped as an open-air school, and special attention is paid to the education of such patients as may suffer from some degree of mental dullness not amounting to certifiable deficiency. Children on reaching the age of 14 years have to be sent home, unless acutely ill, and the only medical care they receive after their discharge is by private medical attendance in their homes or by attending the out-patient department of the Royal Infirmary, the General Hospital, or the Royal Hospital for Women and Children. In the last named hospital about 350 out of an average annual total of 500 surgical in-patients treated are orthopaedic cases. A small proportion of children and adults are treated at the Royal Infirmary and General Hospital; adults requiring prolonged treatment have to be sent to other centres. Children suffering from tuberculous bone or joint disease who do not require operation are admissible to Frenchay, a children's sanatorium situated just outside the city, maintained by the Bristol Health Committee. Here a large number of non-surgical cases of tuberculosis are also treated. Many schemes for co-ordinating and extending orthopaedic work in Bristol have been considered. Negotiations are in progress for combining the work of the Orthopaedic Hospital and the Cripple Children's Society in some closer union than at present exists. If this is accomplished it may be possible to build a much larger hospital containing several hundred beds on a fresh site at a convenient distance outside the city. The numerous hills by which Bristol is surrounded offer almost embarrassing choice of admirable situations. The Cripple Children's Society has already collected £10,000 towards a building fund, but at least another £10,000 will be needed before any scheme can be embarked upon. It is hoped that in any new scheme the claims of cardiac cripples will be stoutly urged and favourably considered.

#### PORT OF MANCHESTER HEALTH REPORT.

The report of Dr. W. F. Dearden, M.O.H. to the Manchester Port Sanitary Authority for the year 1925, just published, contains a series of tables regarding the cases of infectious diseases, notifiable to the authority, reported during the year. The total number so recorded was 139, and shows no definite prevalence of disease in Manchester-bound vessels or in the port. In the ports having communication with Manchester, however, plague and cholera are shown to have existed at Alexandria and Karachi, and there were isolated cases at several other ports, notably Roumanian ports on the Black Sea. The origin and destination of each of the 139 notifiable cases are given in detail in a table occupying a considerable section of the report. Other sections deal with rat destruction, the total number of rats obtained from ships during the year being 2,240, and from dock premises 3,116. Trapping appears to have been the chief method employed for their destruction, and in fact was the only method on ships arriving from infected ports. The remainder of the report gives the results of inspection of food imports and of the sanitary inspection of vessels. In 1925 the number of ships inspected was 2,069, of which 582, or 28.04 per cent., were found insanitary. There has been very little variation in this percentage during the last twenty years; 465 out of 1,494 British ships were insanitary, the next highest numbers being 47 out of 179 Norwegian, and 27 out of 102 United States vessels. The crews numbered 47,164, of whom 34,703 were on British, 3,386 on American, and 3,445 on Norwegian ships. Swedish and Danish ships had crews of 1,492 and 1,489 respectively, but no other nationalities had any great number of ships or crews. The crews of the British ships, it may be noted, were composed of 27,854 Europeans, 6,354 lascars, and 495 Chinese. Details are given of the sanitary defects noted, as also of the sanitary inspection of 811 boats under the Canal Boats Acts. Tables are also included showing the import and export trade of the Port of Manchester; the most interesting being a record of the live cattle trade from Canada; 21,612 were shipped, and of this number only 20 were lost at sea during the year.

#### THE WELSH NATIONAL MEMORIAL ASSOCIATION.

The quarterly meeting of the council of King Edward VII Welsh National Memorial Association was held at Swansea on July 29th. The president, Mr. David Davies, M.P., who was in the chair, said that the financial position was not satisfactory; he suggested that a deputation should be appointed to wait on the Treasury and recall it to a sense of its duty to Wales, which, as compared with English counties, was not receiving a fair share of assistance. He alluded to a report presented to the council by the Medical Committee as to the Spahlinger treatment; three members of the medical staff of the association had, he said, recently visited Geneva, as arranged at the last meeting of council (BRITISH MEDICAL JOURNAL, May 1st, 1926, p. 802). Their report had now been presented to the Medical Committee, which recommended that for the present it should be regarded as confidential, and that three subcommittees should be appointed to consider it and conduct further investigations. These committees would be (1) clinical, (2) bacteriological, and (3) general purposes. The report led to a lively discussion, in the course of which Mr. J. Games, a member of the Monmouthshire County Council, asked for assurance from the chairman of the Medical Committee that the recommendations now submitted by that committee would not in any way thwart the wishes of the council. The chairman, Dr. Enoch Moss of Wrexham, said that there was no such intention. Dr. John Jones (Dolgelley), speaking on behalf of the Merionethshire County Council, opposed the recommendations on the ground that the ratepayers of Wales should not be put to further expense. He thought the true test was whether M. Spahlinger would supply sufficient vaccines and serums to permit of a fair trial, and moved that the council should proceed no further in the matter. The amendment was seconded, but appeals, supported by the president, were made to Dr. John Jones to withdraw it, and eventually he consented. The matter was left in the hands of the Medical Committee to take such action as it might think fit. The report of the principal medical officer stated that decidedly favourable results had followed the further trial of sanocrysin, and that the effects of light treatment at the Glan Ely Hospital had been most striking. He appealed for additional equipment, since many patients, including some thirty sufferers from lupus, were awaiting diagnosis and treatment for both pulmonary and surgical tuberculosis. Such installations were already at work at several of the association's hospitals, but more were needed.

#### THE CARDIGAN HOSPITAL.

The Cardigan Hospital, one of the best of cottage hospitals, owes its present state of efficiency in very large measure to the care which Sir John Lynn-Thomas, K.B.E., F.R.C.S., has given to it. When the people of the district were casting about for a suitable site for a war memorial hospital he pointed to a vacant residence just outside the town, with a garden whose containing wall skirted the foreshore of the river Teifi. It was bought and remodelled internally, and now a flat roof for sun treatment has been formed. Last week Dame Margaret Lloyd George visited the hospital and opened a new electric lift to this flat roof. In doing so she mentioned that when she first visited the hospital it had only six beds; now it had fifteen, which was evidence that the institution was meeting a want. On the same occasion the Vale of Teifi Medical Society, through Dr. T. J. Jenkins, its honorary secretary, presented to the hospital a portrait of Sir John Lynn-Thomas painted by Mr. E. T. Copnall of Liverpool. The portrait was unveiled by the Earl of Lisburne, Lord Lieutenant of Cardiganshire and president of the Cardigan Society in London.

#### PENSION SCHEME FOR HOSPITAL OFFICERS AND NURSES.

Considerable progress has now been made with the plan for a general contributory system of pensions for hospital officers and nurses in London institutions, on the lines of a memorandum issued towards the end of 1924 by a conference of representatives of King Edward's Hospital

Fund for London; the British Hospitals Association, the Incorporated Association of Hospital Officers, and the College of Nursing (JOURNAL, December 19th, 1925, p. 1195). In April the King's Fund invited all the London hospitals to send representatives to a conference at the Mansion House. This conference, which was held on May 19th, was attended by representatives of 89 out of the 136 hospitals on the books of the King's Fund. A memorandum was subsequently drawn up outlining the scheme as approved by the King's Fund for the purpose of special grants-in-aid, and was sent to the hospitals represented at the conference, together with an invitation to a further meeting to decide the preliminary steps. This meeting was held in the House of Lords on July 5th, and was attended by representatives of sixty-two hospitals and of the societies concerned. A provisional council was then formed, including one representative of each participating hospital, two representatives of the Hospital Officers' Association, and two of the College of Nursing. A provisional executive committee to work out the details was constituted as follows: five representatives of participating hospitals with medical schools, five from other participating hospitals, one nominated by the Hospital Officers' Association, and one appointed by the College of Nursing. Hospitals are now invited to submit to this executive committee any point of detail on which they may desire information or decisions. Such questions should be sent to the committee, care of King Edward's Hospital Fund, 7, Walbrook, E.C.4, not later than November 1st. Any hospital which desires to participate and to send a representative to the next meeting of the provisional council is requested to notify the executive committee not later than November 15th. Particulars of the scheme in its present form are embodied in papers entitled *Outline of Scheme as approved by the King's Fund, and Steps taken to start the Scheme*, obtainable from the printer, George Barber, 23, Fumival Street, E.C.4, price 6d. each net, post free.

## Scotland.

### TYPHUS FEVER IN GLASGOW.

A MAN was removed from one of the Glasgow infirmaries to Belvedere Infectious Diseases Hospital on July 30th, suffering from typhus fever. The patient resided in Govan. An inquiry among his family for contacts led to the removal to hospital of a brother and sister who had been taken ill one day and two days previously; another sister became ill on the following day, and a married sister living at some distance was also found to be ill, and was admitted to hospital. Two days later a fourth sister, who is a maid on the staff of a large institution, also sickened, and was likewise transferred to hospital. All these cases are definitely diagnosed as typhus fever. The contacts were removed to a reception house, and on August 2nd one of these persons also developed typhus fever and was removed to hospital. No definite conclusion has been reached as to the source of infection of this group of cases, for the last recorded case of typhus fever in Glasgow was in January, 1923.

### NEW GLASGOW EAR HOSPITAL.

A want has been felt in Glasgow for facilities to deal with diseases of the ear, nose, and throat. There are large special departments in the three infirmaries of the city, but the special hospital was a very small institution. On August 6th the Right Hon. Neville Chamberlain, M.P., Minister of Health, opened the new Glasgow Ear, Nose, and Throat Hospital, a large three-story building, which has just been completed in St. Vincent Street. It contains facilities and modern apparatus for a large out-patient department, and has six wards, containing 48 beds. The hospital also includes an out-patient operating theatre on the ground floor, with well equipped anaesthetic and recovery rooms, and an in-patient operating theatre on the first floor. There are also a large x-ray room, diathermy apparatus, and a laboratory to provide for research work being done in the hospital. The ceremony

was brief owing to the fact that the hospital is now in full operation. After the opening a luncheon was held at the Royal Scottish Automobile Club. Mr. Chamberlain said that the building which he had just opened was a magnificent example of what could be achieved by the voluntary system of the British hospitals. This hospital had begun its career of usefulness fifty-four years ago in a very small way. Under the leadership of Lord Weir, the committee had succeeded in raising no less than £60,000, and to-day the new hospital started upon its career free of debt. This was a great demonstration of the energy, public spirit, and generosity of the Glasgow citizens. Mr. Chamberlain then went on to discuss the future of voluntary hospitals. His remarks are reported elsewhere (p. 313).

### THE ROYAL ASYLUM, PERTH.

The ninety-ninth annual report of James Murray's Royal Asylum, Perth, records the number of admissions for the year ended March 31st, 1926, as 84, the largest number in any year of its history; 59.5 per cent. of the total admissions were on a voluntary basis. During the year 14 patients died, of whom 7 were voluntary boarders. Problems arising in the treatment of mental cases are discussed by Dr. W. D. Chambers, the medical superintendent. Rest in bed in the open air, combined with the process of "insolation," a strictly regulated exposure of increasing areas of the body to the direct rays of the sun, and the use of the ultra-violet rays produced by a mercury vapour lamp, have yielded good results. In addition to these general measures, foci of infection are sought for and eradicated. Psychotherapy is in constant use, and is considered to be of great service, and the only line of treatment yielding good results in treating the psychoneuroses.

### CENTRAL MIDWIVES BOARD FOR SCOTLAND.

The examination of the Board, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, has just been concluded with the following results: Out of 142 candidates who appeared for the examination 127 passed. Of the successful candidates, 32 were trained at the Royal Maternity Hospital, Edinburgh, 26 at the Royal Maternity Hospital, Glasgow, 7 at the Maternity Hospital, Aberdeen, 9 at the Maternity Hospital, Dundee, 14 at the Queen Victoria Jubilee Institute, Edinburgh, and the remainder at various other recognized institutions.

## Ireland.

### MEDICAL REGISTRATION (IRISH FREE STATE).

THE Free State Medical Act was to expire this month, but as a decision on the medical registration question has not yet been reached the power conferred by it to maintain the existing registration machinery in operation from month to month has been taken advantage of, and the Executive Council has made the first continuance order under the Act, extending the period for which the Act is to remain in force until September 21st next.

### MILK SUPPLY IN THE FREE STATE.

The committee appointed by the Minister for Local Government and Public Health to inquire into the conditions of milk production in the Free State consists of Mr. R. Wilson, T.D. (chairman), Dr. T. Hennessy, F.R.C.S.I., T.D., Mr. P. K. Hogan, T.D., Sir William J. Thompson, M.D., Dr. E. F. Stephenson (Ministry of Local Government and Public Health), Dr. M. J. Russell, F.R.C.S.I. (Medical Officer of Health, Dublin), Messrs. P. E. Dolan, M.R.C.V.S., J. Johnson, P. O'Connor, and L. S. Smyth, and has held its first meeting, when it was decided to invite evidence, at the outset, from the Dublin Corporation, from organizations connected with the Dublin milk supply, from the Irish Agricultural Organization Society, the Irish Farmers' Union, the Creamery Managers' Association, and from inspectors of the Local Government Department. The committee will be prepared to hear any person who notifies his readiness to give evidence.

and submits a précis to the Secretary, Committee on Milk Supply, Department of Local Government and Public Health, Upper Merrion Street, Dublin.

#### HEALTH OF A NORTH OF IRELAND SEAPORT.

Coleraine, a small seaport of some seven thousand people on the north-east coast of Londonderry, was recently visited by Dr. Patrick, one of the medical inspectors of the Ministry for Home Affairs of Northern Ireland, who found the general sanitary conditions satisfactory, but recommended that one of the slaughterhouses should be closed. He recommended further that a public abattoir should be established, and the meat supply systematically inspected. The condition of the cowsheds was, on the whole, fair, but the Ministry recommends that samples of the milk sold in the district should be submitted from time to time to bacteriological examination. Some of the houses are of a poor type in the urban district, but the council is considering the building of new houses. The maternity and child welfare scheme was working satisfactorily, but there had been some difficulty about the water supply. It was sufficient in quantity, being equivalent to 35 gallons a head of the population, but when the higher levels were being supplied the water had to be turned off in other parts—a dangerous state of things. Sanitation generally had improved, and there was not the same amount of promiscuous dumping of house refuse and rubbish on waste ground; but there were still heaps of manure which should be removed at least once a week, and the cleansing of ashpits, which should be covered, should be insisted on at frequent intervals. The fever hospital accommodation was not up to date.

## Correspondence.

### MINER'S NYSTAGMUS.

Sir,—Dr. A. S. Percival, when discussing the relation-ship of miner's nystagmus to illumination (BRITISH MEDICAL JOURNAL, July 31st, p. 224), states that the new cases of nystagmus, 163 in number, which were observed in certain pits in Northumberland and Durham in 1912 were by no means evenly distributed among the underground workers, for the coal hewers showed an incidence of 0.90 per cent., and the other underground workers one of 0.24 per cent., or about a fourth as much. Again, in one pit where electric safety lamps were used exclusively nearly 4.3 per cent. of the hewers acquired the disease, but only 1.3 per cent. of the non-hewers. In a second pit where at one time (twenty-five years ago) electric lamps were used exclusively the percentage of cases of nystagmus was notoriously high, but on replacing these lamps with safety oil lamps the number of cases among the non-hewers fell to zero, while there were very few among the hewers. Dr. Percival considers that this evidence definitely confirms the conclusion of the Miners' Nystagmus Committee to the effect that "the essential factor in the production of miners' nystagmus is deficient illumination."

Dr. Percival's conclusion does not by any means follow from the facts stated, for he has omitted to take several important factors into consideration. The coal hewers suffer more eye-strain than most other underground workers for two reasons. First, they have a greater need of accurate vision, and especially so when they are setting the props which keep the roof from falling. To do this job properly they have to fix the props and wedges in position by accurately placed blows with a hammer. Then again it is desirable for the hewers to see the coal face clearly, so that they may strike with the pick to the best advantage. Further, the hewers do not get such a good light as the other underground workers. The air around them is frequently thick with coal dust, and though I have not made any measurements I should think that this dust often reduces the effective illumination of the coal face by a half. In the airways of the mine, however, where most of the other underground men are working, there is very little suspended coal dust. Moreover, some of these airways are stone dusted, and this greatly increases the proportion of light reflected from the surface, as compared with that from the coal face.

Dr. Percival's argument that electric lamps, though more powerful than safety oil lamps, have a greater nystagmus effect, is a doubtful one. The Miners' Nystagmus Committee found that the safety oil lamps tested by them had an average luminous intensity of 0.54 candle, whilst the electric lamps had one of 0.655 candle, or 23 per cent. more; but these observations were made with the flame or filament of the lamp in the broadside-on position. According to my own observations, these values, if converted into terms of the mean all-round luminous intensity of the lamps, would fall to 0.516 candle for oil lamps and to 0.515 candle for electric lamps; that is to say, they would show no difference in favour of the electric lamp. It should be pointed out, however, that the lamps were tested at the surface of the pit and not at the coal face, where the oil lamp may lose much of its luminous intensity owing to deficient oxygen. In any case, the present-day electric lamp is not a great improvement on the present-day oil lamp, and the electric lamp of twenty-five years ago, which is referred to by Dr. Percival, may have been worse than the oil lamp which was used subsequently.

On the other hand, the electric lamp has one defect which may be of great importance in the causation of miner's nystagmus, though direct evidence is lacking. The lamp causes a pronounced glare effect, owing to its white-hot filament, whereas the oil lamp flame is soft and pleasant to the eye. The glare causes discomfort and even pain when the lamp is viewed by the dark-adapted eye, and it is noticeable that the coal hewer, when shifting his lamp from place to place, as he has to do at frequent intervals, does not look at it directly if he can avoid doing so. Mr. S. Adams, Mr. T. Bedford, and I found that the pain caused by looking at an electric lamp (fixed two feet from the eyes) for two seconds, continued to increase for the first three hours we were underground, owing to increasing dark-adaptation. The viewing causes pronounced after-images, persisting for one or two minutes, and these images are strong enough to diminish appreciably one's accuracy of aim—for example, when attempting to prick small white spots on a black background. Fortunately the glare effect of electric lamps can easily be reduced by frosting the lamp glasses, though this remedy has not yet come into general use.—I am, etc.,

Oxford, July 31st.

H. M. VERNON.

### ORAL ADMINISTRATION OF PANCREATIC PREPARATIONS IN THE TREATMENT OF DIABETES.

Sir,—We do not share the optimism displayed so prominently among your advertisements by the makers of "trypsogen" and other similar products regarding the value of such preparations in the treatment of diabetes. From close and fully controlled observations on patients we have never found any preparation of pancreas taken by mouth to be of the slightest value in the treatment of diabetes. We would welcome concrete proof that some useful mouth preparation really exists, because oral administration of tablets is obviously preferable to injections of insulin and the tedious necessity of dieting. But until we are convinced, by the results of detailed experiments in which the diet and other factors are fully controlled, that any such exist, we feel bound to affirm that such preparations are utterly useless. In such a disease as diabetes, in which the results of treatment can be controlled and estimated with something approaching the accuracy of pure mathematics, definite proof can be obtained.

We are not prepared to accept optimistic reports of their therapeutic value unless such reports are based on carefully controlled work. Patients usually commence a restricted diet at the same time as they begin to take these preparations, and, in our opinion, the benefit is derived entirely from the dietetic change. The fact that the patient has to swallow some half-dozen pills at the end of his meal also tends to make him careful in what he eats, and may contribute largely to the apparently happy action of these pills in some cases.

We therefore feel justified in asking space to warn the profession against undue optimism over such preparations. It is not conducive to silence to have seen patients grow

steadily worse in spite of the prolonged use of such preparations, and to have had to rescue them from a miserable death by the use of insulin.—We are, etc.,

H. MACLEAN.  
R. D. LAWRENCE.

London, W., July 29th.

### THE PROPHYLACTIC VALUE OF SCARLET FEVER ANTITOXIN.

SIR,—Dr. J. H. Garrett's reply in your issue of July 31st at least serves to make clearer to me what our difference is. He is not satisfied that the Dick test is a reliable index of susceptibility or otherwise to scarlet fever; whereas we, after a daily experience of the test for the past two years, believe it to be so.

Working in conjunction with two groups of bacteriologists of repute, and with toxins produced independently by them, our aggregate of Dick tests approaches 3,000. We believe as a result of our experience, which is daily being enlarged, that an individual who gives a negative response to an adequate skin dose of Dick toxin is immune to scarlet fever—by which we mean the toxicæmic manifestations produced by the *Streptococcus scarlatinae*. We know, for example, that cases sent in with a diagnosis of scarlet fever but who present no signs or symptoms of the disease, or who are palpably suffering from something else, may be safely nursed in a scarlet fever ward (a) if they are primarily Dick-negative, or (b) rendered Dick-negative by a prophylactic dose of scarlet fever antitoxin. In the latter case they remain immune for a matter of days only, and then again become Dick-positive and susceptible. Whether they are Dick-negative on admission or the condition is produced artificially, the presence of scarlet fever antitoxin can be demonstrated in their blood; their own serum in either case will produce local blanching when injected intradermally in a dose of 0.2 c.cm. into a recent scarlet fever rash—the well known Schultz-Charlton reaction.

For the moment I must ask Dr. Garrett to accept this brief statement. Some of our work on the Dick test has already been published (*Public Health*, May, 1926); a more extended series of observations is at present being prepared for publication.

Nobody realizes better than ourselves that there are difficulties and things not as yet satisfactorily explained; but the broad facts outlined above stand out. May I reiterate that a skin test dose of Dick toxin was the criterion adopted in the paper which Dr. Garrett criticizes? These readings might, indeed, have been carried out on any series of individuals with, *mutatis mutandis*, the same results: so many susceptible to a skin test dose of toxin; so many rendered temporarily immune, as shown by a negative test after administration of serum; so many, again, showing waning or complete loss of immunity—for example, the Dick test again becomes positive—after a lapse of days. As a fact, the occurrence of an initial case of scarlet fever in the ward formed a mere *point d'appui*.

The assumption with which Dr. Garrett credits me that 100 per cent. of susceptibles would necessarily contract scarlet fever is one which it would never occur to me to make. Neither did I quote Dr. Kirkhope's paper "to buttress my position," but only to draw attention to an independent series of observations under different conditions and with another criterion of susceptibility.

With a further assurance to Dr. Garrett that I write only of what I know from very careful and repeated observations, I must take my leave of him in your columns.—I am, etc.,

Birmingham, Aug. 2nd.

E. H. R. HARRIES.

### DEFENCE OF ASSISTANTS AND LOCUMTENENTS.

SIR,—The letter in your issue of July 31st from the secretaries of two of the defence societies (Medical Defence Union and London and Counties Medical Protection Society) records a reciprocal arrangement which is both welcome and obvious common sense. Might I ask why the Medical and Dental Defence Union of Scotland—to which a large number of doctors belong—is not included in such an agreement? Until all such societies are linked

up by reciprocal agreements, doctors cannot be adequately protected.

The importance of medical defence to the individual cannot be overestimated, as no doctor can foresee when his services may be called in question. The letter referred to deals with the specified condition that all the parties concerned belong to one or other of the two defence societies mentioned. It would have been valuable had they in addition warned those who are anxious to be protected of some of the existing weak spots in their armour.

**Assistants.**—A member of either of these societies is not protected against an action arising from the acts or omissions of an assistant who is not also a member of one or other of them, nor is he protected, unless a reciprocal arrangement exists, if his assistant belongs to the Medical and Dental Defence Union of Scotland. Many assistants are engaged by doctors without, so far as I know, any inquiry being made on this important point.

**Hospital Consultants.**—It is only implied that they will defend a member if his subordinate is also a member of one or other of the two societies. No reference is made to the hospital consultant who is a member, and who is liable to legal expenses should his treatment be called in question, and whose junior (the resident responsible for the action) is not a member, which is usually the case. Consultants are all too prone to feel that the committee of management or house committee—whichever term is used—will be held solely responsible for the acts of the residents it appoints. In strict law I understand this is not the case. Sisters and nurses, of course, are not members of any defence society.

**Locumtenents.**—The Medical Defence Union, in the *BRITISH MEDICAL JOURNAL* of March 27th, stated that it will afford the usual cover to its members for the acts or omissions of "any registered medical practitioner, while temporarily employed as a locumtenent." The other defence society (the London and Counties Medical Protection Society) makes no statement on the matter. It is highly important that this point should be settled at the earliest possible date. The vast majority of locumtenents are recently qualified men who have not yet realized the risks and responsibilities of practice, but there are others who engage in locumtenent work—namely:

1. The habitual locumtenent, who may be quite a senior member of the profession.
2. The man engaged in whole-time administrative work who does a casual locumtenency.
3. The neighbouring practitioner (not a member) who looks after the practice of a friend (a member) during his absence.

One might reasonably ask for a clear definition of what constitutes a "locumtenent" and "assistantship," and is No. 3 recognized as a locumtenent? Also, When does a long locumtenency become a short assistantship?

The Medical and Dental Defence Union of Scotland, in the *BRITISH MEDICAL JOURNAL* of August 7th, states that its members are covered against actions arising out of the acts or omissions of their assistants or locumtenents. There are very strong reasons why the medical defence societies in these islands should have a comprehensive reciprocal arrangement, and that the protection on the matters referred to should be on a sound and clear basis.—I am, etc.,

E. FARQUHAR MURRAY, M.D., F.R.C.S.,  
Honorary Secretary, Newcastle-on-Tyne Division,  
British Medical Association.

Newcastle-on-Tyne, Aug. 9th.

### OBSTRUCTION AT THE VESICAL OUTLET AFTER PROSTATECTOMY.

SIR,—Mr. Ainsworth-Davis (July 31st, p. 226) credits me with diagnosing a fibrous type of prostatic enlargement in the three cases I recently described under the above heading, and suggests that diathermy was the proper treatment. Even had I diagnosed the exact conditions I found on operating, I should not have tried diathermy with any brand of instrument. However successful it may be in cases of an obstructing bar or membrane, it is certainly not suitable for every fibrous enlargement of

the prostate. Ho says it never leads to subsequent contraction, but "never" is a very wide term. I certainly should not have operated had dilatation been effectual. In these cases it is sometimes impossible to find an opening at all, and frequently difficult to get a fine bougie through. I can imagine using a Kollmann's dilator once, but cannot see the patient returning for a repetition of the process.

I tried to emphasize the importance of early catheterization. Routine packing of the prostatic cavity for forty-eight hours after the operation would involve quite unnecessary discomfort, pain, and danger for the patient, and could not have any good effect on the condition to which I refer in my article.—I am, etc.,

London, W.1, Aug. 7th.

W. K. IRWIN.

### MIDDLE-EAR DEAFNESS.

Sir,—We are indebted to Mr. Barnett for pointing out (July 31st, p. 227) the mistakes in the synopsis of our paper on the effects of radium treatment in chronic non-suppurative middle-ear disease, with resulting deafness, as published in the BRITISH MEDICAL JOURNAL of June 26th (p. 1087).

Both these errors were made only in this summary, and neither was made in the communication itself as read before the Surgical Section of the Royal Academy of Medicine in Ireland on May 21st, 1926. In reading the paper we quoted Sir William Milligan's opening remarks, and also gave the views of later speakers at the meeting of the Section of Otology of the British Medical Association conference at Bath last year. We did not state that treatment was universally admitted to be most unsatisfactory. We also gave due credit to the fact that oto-sclerosis was specifically excluded from the discussion on this occasion.—We are, etc.,

Dublin, Aug. 4th.

W. C. STEVENSON.  
T. G. WILSON.

### Obituary.

AFTER some months of illness Dr. HERBERT EDMONDSON, of Burnley, died at his residence on July 13th, at the age of 50. He was educated at Repton, Cambridge, and the London Hospital, graduating M.B., B.Ch. in 1901. He became widely known in East Lancashire as an ophthalmic surgeon, and had been in practice in Burnley for about twenty-five years. Dr. Edmondson was honorary ophthalmic and aural surgeon at the Burnley Victoria Hospital for over twenty years, and also held the appointments of ophthalmic surgeon to the Burnley Miners' Relief Society, and honorary ophthalmic surgeon to the Accrington Blind Society. He was an active and enthusiastic member of the British Medical Association, and for several years was on the executive committee of the Burnley Division, of which he was chairman in 1922-23. He leaves a widow and one son.

Dr. EDGAR WILLIAM SEYMOUR (formerly Hoffmeister), who died at Cowes, Isle of Wight, on July 25th, aged 58, was the son of the late Dr. William Hoffmeister, M.V.O., whom he succeeded as Surgeon Apothecary to Queen Victoria and the Royal Family in the Isle of Wight. Dr. Seymour received his medical education at Cambridge, B.Ch. in 1893, and obtained the diplomas M.R.C.S., L.R.C.P. in the same year. He was surgeon-in-ordinary to Princess Beatrice, surgeon to the Royal Yacht Squadron, and was at one time consulting physician and medical officer to the Osborne House Officers' Convalescent Home. He was made a Member of the Victorian Order in 1912. He took an active interest in cricket and had been a member of the Cambridge and Hampshire elevens. He was for some time honorary secretary of the Cowes Golf Club. Dr. Seymour retired from general practice some years ago, and leaves a widow, but no children.

### The Services.

#### MEMORIAL TO SIR HARRY THOMPSON.

A STAINED glass window, erected in the chapel of the Queen Alexandra Military Hospital, Millbank, in memory of the late Major-General Sir Harry Thompson, A.M.S., who died in 1925, was unveiled, on August 4th, by Lieut.-General Sir Matthew Fell, Director-General of the Army Medical Service. In the course of the ceremony, Sir Matthew Fell referred to an incident at Lucknow, in 1850, when Sir Harry Thompson, regardless of his own personal safety and comfort, nursed a camp full of men suffering from cholera. The window, which is next to one shortly to be unveiled to the founder of the hospital, Queen Alexandra, contains two subjects: "The Healing of Bartimaeus" and "The Raising of the Widow's Son at Nain"; it bears the inscription "In loving memory of Major-General Sir Harry N. Thompson, K.C.M.G., C.B., D.S.O."

### Universities and Colleges.

#### UNIVERSITY OF LONDON.

At the meeting of the Senate held on July 21st the following were recognized as teachers of the University in the subjects indicated: (physiology). *St. Thomas's Hospital Medical School*.—Dr. A. St. G. J. McC. Haggett (physiology). *Guy's Hospital Medical School*.—Dr. R. D. Gillespie (psychological medicine). *Bedford College*.—Mrs. Nora Edkins (physiology).

The resignation of Dr. Major Greewood from the University Readership in Medical Statistics at University College was accepted as from July 31st. It was resolved to institute a Readership in Medical Statistics at University College.

A grant of £20 has been made to Dr. K. N. G. Bailey from the Thomas Smythe Hughes Fund towards the cost of an investigation of certain strains of the *Bacillus coli* having haemolytic properties, to determine whether this property is peculiar to these strains or not, and whether this haemolytic action by the bacillus is of pathogenic importance in certain conditions of the intestinal and urinary tracts.

The Senate adopted the following resolution: That the Co-ordination and Developments Committee be authorized to take immediate steps to secure for the University the longest possible continuance of the temporary occupation of the Malet Street site, on the understanding that the Senate will be prepared to continue negotiations for the acquisition of so much of the Bloomsbury site as is practicable, having regard to the urgent importance of increased accommodation for the University at South Kensington.

#### NATIONAL UNIVERSITY OF IRELAND.

THE *Calendar* for 1926 of the National University of Ireland has recently been issued. It contains an account of the establishment and constitution of the University, together with a description of its general organization. Details are given of the regulations of the University and its constituent colleges, together with lists of the successful candidates at the examinations in 1925. Full information about the travelling studentships in connexion with the University and the various examinations is included.

#### CONJOINT BOARD IN SCOTLAND.

THE following candidates have been approved at the examination indicated:

FINAL EXAMINATION.—(Medicine): O. D. Beetham, B. S. Ellis, A. E. F. L. Forbes, W. L. G. Jewitt, H. S. Kent, P. R. C. Peterson, K. M. R. Swami. (Surgery): Elizabeth Bell, N. M. Eadie, B. S. Ellis, A. E. F. L. Forbes, J. Hendry, S. A. B. Hosang, H. B. S. Ellis, J. V. O'K. Murphy, A. S. Pool, D. B. J. de Silva, Rosie Swamikan. (Midwifery): A. S. Arora, S. E. W. Bolland, N. M. Eadie, S. P. H. Gunawardena, O. Ap. V. J. nes, C. M. Macintyre, J. A. Minin, H. B. Martin, P. R. C. Peterson, D. B. J. de Silva, Rosie Swamikan, Couster, J. J. Craig, S. W. Crickshank, L. M. Davies, I. A. Cameron, A. G. Campbell, J. W. A. M. McGinness, N. Macleod, G. W. Milledge, V. Nath, W. T. A. Pearce, G. D. Roche, J. J. S. F. e Souza, E. E. M. Steen, E. M. Stone.

The following, having passed the final examination, have been admitted L.R.C.P.Ed., L.R.C.S.Ed., and L.R.F.P.S.Glasg.: Gwendoline R. Andrews, W. B. Anderson, M. M. Bronstein, Ann J. Brown, G. V. Boyle, S. N. Catterjee, L. Checchi, C. S. Chew, Mary D. Clark, J. Cook, A. H. Edgar, H. J. Fernando, M. T. Fernando, J. B. Fischbacher, S. A. S. Hamilton, P. Henry, S. A. Hunt, J. B. Hutchison, S. John, J. E. Kennedy, J. A. Lavery, R. J. B. Macintyre, Jeannina M. McKendrick, J. Marcolles, J. M. Muschamp, J. R. R. Menon, K. P. Menon, J. Mindess, Emma C. M. R. K. Ramm, W. Read, W. Robinson, P. D. Samarasinghe, V. D. Secarevitz, R. V. N. Selvadurai, E. T. Shadforth, D. S. de Simon, J. A. Sivardene, J. B. Stronifer, J. T. M. Symington, C. E. Toh, E. P. Tulloh, D. R. Wark, C. H. Wickremesinghe, N. Wijeyesekera.

#### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE College will close for the long vacation on August 14th, and reopen on Monday, September 20th.

<sup>1</sup>The National University of Ireland: *Calendar for the Year 1926*. Dublin: Alex. Thom and Co., Ltd. 1926. (41 x 72.)

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

On August 4th, on the motion that the House of Commons adjourn till November 9th, Mr. Hardie remarked that after an excessively strenuous period of work it was impossible to recuperate in three months. The work of the House should be arranged so that there never would be any all-night sittings nor any attempt to crush six months' work into three months. They should organize so as to get the rest necessary for recuperation and to carry on work continuously at a high level of nervous expenditure. At present the House did not do that, and after the first three weeks of the session the occupants of the Government front bench looked as if they were going to have early funerals. They would never get health with the self-inflicted over strenuous periods of the present system. The motion to rise till November 9th was carried.

### The Factories Bill.

The Factories Bill, which was introduced into the House of Commons on August 2nd by the Home Secretary, Sir William Joynson-Hicks, closely follows, though with some omissions, the bill tabled by Mr. Arthur Henderson when Home Secretary in 1924. It is chiefly a codification of existing Factory Acts and Orders, but makes considerable changes in the law, not only in nomenclature, as when "certifying surgeons" become "appointed doctors," but in substance.

The bill abolishes the distinctions between factories and workshops and between textile and non-textile factories. Provisions relating to the sanitary conditions of workshops, to cleanliness, overcrowding, ventilation, and the drainage of floors, and to the provision of sanitary conveniences, are now enforceable in the first instance by the local sanitary authorities—with certain exceptions in the last regard. The bill proposes that they shall be enforceable by the factory inspectors save in any factory where mechanical power is not used and which forms part of a dwelling-house or shop in the same occupation. There the provisions are to be enforced by the sanitary authority, to whom the Home Secretary may also delegate similar powers over other factories not employing mechanical power. The bill expands previous legal definitions of a factory to include railway lines and sidings, premises where materials or articles are sorted as a preliminary to work in any factory, where bottles or containers are filled or articles packed, and for adapting stage properties and dresses. The application to electricity works is extended. Premises adjacent to a mine or quarry used solely for processes ancillary to the getting and preparation of minerals are not to be deemed a factory.

In the clause dealing with cleanliness in factories provision is made that the floor of each workroom must be cleaned at least once weekly. The obligation to paint or whitewash walls is extended to partitions; those with smooth, impervious surfaces must be washed with soap and water at least every fourteen months. The provisions about whitewashing or painting will not apply to factories without mechanical power and employing fewer than ten persons unless the inspector so requires.

Under the existing law, the cubic space to be allowed to each person is 250 ft. at ordinary times, and 400 ft. during overtime. The clause substitutes 400 ft. at all times for rooms not used as workrooms before the passing of the Act. It also excludes from the calculation of the cubic space, space more than 14 ft. from the floor. A new provision enjoin that where the work is chiefly done sitting the temperature shall not after the first hour fall below 60°. The Home Secretary may by special order prescribe a reasonable temperature for any class or parts of factories and prohibit means which may be injurious for maintaining temperatures. He may also prescribe a standard of lighting for factories. All windows and skylights are to be kept clean as far as practicable on both sides and free from obstructions. A new provision lays it down that "Where it appears to the Secretary of State that in view of the amount of sickness among the workers in any factory or class or description of factories or for some other reason that special provision ought to be made at that factory or at factories of that class or description to secure the health of persons employed therein, he may, after consultation with the Minister of Health, by order require the occupier to make such reasonable provision by arrangements for the special medical supervision of the workers and otherwise (but not so as to include medical treatment) as may be specified in the order."

The law relating to the fencing of machinery is extended and a new statutory provision made for fencing vessels containing scalding, corrosive, or poisonous liquids. Safeguards are made about work in places where dangerous fumes may be encountered. Suitable breathing apparatus and oxygen reviving apparatus must be provided. The provisions relating to means of escape from fire are amplified and applied to factories employing fewer than forty persons. Fire drill is ordered in some factories. The maintenance of a supply of drinking water is to be enforced, and the provision of first-aid boxes, which has been in force since 1921, is continued. Seats must be provided for female workers whose work is done standing, and protective clothing where prescribed as necessary. In making orders about welfare the Home Secretary may impose duties upon employees.

(Clauses in Mr. Henderson's bill relating to washing facilities and facilities for drying clothes are dropped from the new measure. So also is the clause prohibiting after five years the use of shuttles capable of being threaded by suction of the mouth.) The present bill extends the obligation to protect workers from dust and fumes. No meals are to be allowed in any workroom where highly siliceous dust is given off, and a penalty is provided against employees spitting where that is prohibited by notice. The age at which girls may be employed in salt works is raised to 12. In tenement factories where metals are ground the provision made by Order for a clear space between the grindstones and the wall is amended to allow the use of splashboards. Provision is made for the maintenance of wet and dry bulb thermometers in all factories where humidity is artificially produced, and a table of the permitted relation between the two readings is provided. Inspectors are given power to forbid the carrying on of certain trades in unsuitable underground rooms. These trades include the preparation of food for human consumption. No basement bake-houses are to be established after the passing of the Act. The district council is to enforce this provision. In general the Secretary of State takes power to make regulations for the safety or health of persons employed in any process without the need for a prior certificate that the process is dangerous.

To the obligation of any medical practitioner attending on a patient suffering from lead, phosphorus, arsenical, or mercurial poisoning, or anthrax, contracted in a factory, to report that illness, is now added the obligation to send the Chief Inspector of Factories the name and address of the factory. The court can order the expenses of witnesses at inquiries into factory accidents or diseases to be paid by the person held responsible in any way for the occurrence. In the next clause "appointed doctors" are substituted for "certifying surgeons," but with no change of powers. Hours of employment are made the same in textile as in non-textile factories, and the overtime regulation is altered. An extended provision enjoins that where the Home Secretary thinks a special provision requisite for the protection of the health of women or young persons employed under a special exception he can order the provision to be a condition of employment.

The bill recasts the rules for the issue by the appointed doctor of certificates of fitness for employment of young persons under the age of 16. Power is given to the Home Secretary to exempt from the section any works where mechanical power is not used. A later clause provides that the Home Secretary shall fix the fee to be paid to the appointed doctors. The fee for examination of young persons, or of other employees in pursuance of regulations, is to be paid by the occupier of the factory; in other cases by the Treasury.

The application of factory legislation to docks, wharves, quays and warehouses is widened. Certain provisions of the bill are extended to all building works. These include those relating to sanitary conveniences. Similar extension is made to engineering works and to lines and sidings in connexion therewith. The bill is also applicable to building operations and engineering work undertaken for the Crown.

### The Lead Paint Bill.

On August 3rd the House of Commons considered, on report the Lead Paint (Protection against Poisoning) Bill. Mr. Rhy Davies moved a new clause to prohibit the use of lead paint for interior painting, with certain exceptions. He said the amendment would implement the Geneva Convention, for which the Labour party stood. Regulations somewhat similar to those which the Government proposed for painting had been introduced in 1913 for the pottery industry, but had not prevented lead poisoning, which had increased in that industry during thirteen years. Mr. Montague said medical evidence was overwhelming in favour of prohibition. Major Halls said that eventually lead would have to be prohibited, both in paint and in pottery glaze. Mr. Wallhead said lead poisoning induced nervous diseases, and added to the danger of Bright's disease. Dr. Watts asked if Mr. Wallhead was aware of the danger in the use of zinc. Mr. Wallhead said there was no danger when zinc was prepared as a paint. Captain Hacking, for the Home Office, thought that regulations failed to reduce the death rate from lead poisoning very largely the Home Secretary would introduce a more drastic bill with prohibition as its essence. The proposed new clause was rejected by 198 to 74. Dr. Watts moved that the medical examination of painters proposed in the bill should be made monthly. Captain Hacking offered to accept the word "periodical" instead of "monthly," and Dr. Watts withdrew his amendment and "periodical" was inserted. The House rejected a further amendment by Dr. Watts which proposed that the examination should be by a certifying factory surgeon. Sir Robert Newman moved that the clause "employment of women or young persons in lead paint should be amended by leaving women or." He asked why, if the proposed regulations were to remove the danger of lead poisoning, women could not join in the occupation as well as men. Mr. Hurst seconded, and said hundreds of women were employed in this work. Dr. Haden Guest said that the fact that lead poisoning was an important cause of abortion was a sufficient reason to protect women more than men. Captain Hacking hoped the House would not accept the amendment. Sir Thomas Oliver had said that "on the whole females suffered more severely from plumbism than males," and Sir Thomas Legge, Chief Medical Inspector of Factories at the Home Office, said "women are more susceptible to poisoning by lead than men." The amendment was rejected, and the bill was read a third time. It was read a first time by the House of Lords on August 4th.

## Medical News.

At a meeting at the Post-Graduate Hostel, Imperial Hotel, Russell Square, W.C.1, on August 5th, Dr. Manson-Bahr maintained that the clinical side of tropical medicine should be studied best outside the tropics. In the course of his remarks he referred to a drug introduced for the treatment of amoebic dysentery which had been successfully employed in ulcerative colitis. Blackwater fever—which, he said, always affected mild or latent cases of malaria—was, he thought, probably anaphylactic in nature. He praised Bayer 205, which had gone a long way in the successful treatment of sleeping sickness, and made a plea for increased help of the ichemist in the fight against tropical diseases. Lieutenant Mackie, I.M.S., who was in the chair, observed that an optical disease might be latent for many months, and agreed at the clinical side of tropical diseases was best studied in a country, where hospital and laboratory facilities were excellent.

THE Fellowship of Medicine announces that a special all-day course will be held at the Queen's Hospital for Children from August 16th to 28th. An all-day revision course in medicine, surgery, and the specialties at the Queen Mary's Hospital, Stratford, will continue from August 23rd to September 4th. Continuous weekly courses in obstetrics and the Fellowship can also provide practical courses in anaesthetics. From September 6th for four weeks special lecture demonstrations, on the more important diseases of the eye, will be arranged at the Central London Ophthalmic Hospital. From September 6th also eight bi-weekly lecture demonstrations in psychological medicine will be given at the Bethlehem Royal Hospital. From September 13th to 25th the Infants Hospital will hold a course for medical officers of welfare centres and others. Between September 20th and October 1st the Westminster Hospital will provide an intensive course in medicine, surgery, and the specialties; the National Orthopedic Hospital will hold an all-day course from September 20th to October 2nd, and on successive Wednesdays, beginning September 22nd, Dr. Heald will give four lecture demonstrations on electrotherapy. Copies of all syllabuses, the general course programme, and the Fellowship journal may be obtained from the Secretary, 1, Wimpole Street, W.1.

A THREE months' course of lectures and demonstrations in hospital administration complying with the regulations of the General Medical Council will be given by the Medical Superintendent on Monday, October 4th, at the North-Eastern Hospital of the Metropolitan Asylums Board, St. Ann's Road, Tottenham, N.15. Further particulars can be obtained from the Clerk to the Metropolitan Asylums Board, Victoria Embankment, E.C.4.

THE Lord Mayor of Liverpool (Mr. F. C. Bowring) has accepted the invitation to be chairman of the Liverpool School of Tropical Medicine in succession to the late Sir Francis Danson.

THE Rockefeller Institute has presented the Norwegian Government with a million gold crowns for a State serum and vaccine institute.

PROFESSOR CAESAR ROUX, the well known surgeon of Lausanne, and Professor G. Winter, who held the chair of obstetrics at Königsberg, have been made emeritus professors in their respective universities.

At the recent congress held in Brussels entitled "Journées médicales de Bruxelles" papers on the following, among other subjects, were read: the antisyphilitic campaign in Belgium, by Professor A. Bayet; vaccine therapy of acute microbial affections, by Dr. Bertrand; the surgery of cerebral tumours, by Dr. de Martel; the surgery of pain, by Professor Sicard; the onset of human tuberculosis, by Professor Léon Bernard; treatment by ultra-violet rays, by Dr. Dekeyser; and radium treatment of cancer, by Dr. L. Mayer. A special excursion was made to Louvain, where the degree of doctor honoris causa was conferred on Marshal Lyautey by the university.

THE History of Medicine Institute at Leipzig, founded by Professor Karl Sudhoff, and now under the direction of Professor Henry E. Sigerist, in addition to a well stocked library, contains a collection of over 10,000 photographs, as well as models and instruments for teaching purposes.

THE German Röntgen Society will hold its annual meeting at Düsseldorf from September 22nd to 24th, when the following subjects will be discussed: X-ray treatment of inflammation, introduced by Heidenheim of Worms, Porges of Vienna, and Wagner of Prague; the Compton effect, introduced by Friedrich of Berlin; irradiation of the ovary and offspring, introduced by Martinus of Bonn and Nürnberg of Hamburg.

THE following international post-graduate medical courses will be held in Berlin in October. From October 4th to 16th there will be a course in general medicine, with special reference to the latest progress in therapeutics, and from the 18th to the 30th a course in neurology; a fortnight's course will commence on October 18th in specialties, and a month's course on October 4th. Further information may be obtained from the secretary of the International Post-Graduate Medical Courses, Kaiserin Friedrich-Haus, Luisenplatz 2-4, Berlin, N.W.6.

THE congress known as the Journées médicales de Montpellier, organized by Professors Ducaup, Delmas, and Faucon, will be held at Montpellier from November 4th to 7th, when the centenary of the medical clinic and the discovery of bromine by the Montpellier chemist Balard will be celebrated.

THE German society for the study of diseases of digestion and metabolism will hold a congress in Berlin under the presidency of Professor von Bergmann of Frankfurt from October 13th to 16th.

THE third International Congress of Individual Psychology will be held at Düsseldorf from September 26th to 29th. Further information can be obtained from Dr. Maximilian Reis, Friedenstrasse 20.1, Dortmund.

DR. H. ALDERSHOFF, director of the State Serological Institute at Utrecht, has prepared a serum from sheep immunized against vaccinia for use in cases of post-vaccinal encephalitis. The serum, which should be administered as early as possible after appearance of the symptoms, will be sent free of charge to practitioners attending a case of post-vaccinal encephalitis.

THE July issue of *Boletín Técnico de la Dirección general de Sanidad*, a bi-monthly journal recently started by the Spanish Ministry of Health, contains articles by Dr. Andrés López Prior on a focus of pellagra in Caldas de Reyes, by Dr. F. Beato on the etiology of scarlet fever, and by Dr. F. F. García on an official method for the examination of oysters; and statistical tables of births and deaths in the various provinces of Spain during the months of January, February, and March, as well as abstracts from current literature and medical news.

PROFESSOR ROGER has been re-elected dean of the Paris Faculty of Medicine.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to THE EDITOR, *British Medical Journal*, British Medical Association House, Tavistock Square, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

THE TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are: *MUSEUM* 9361, 9362, 9363, and 9364 (internal exchange, four lines).

THE TELEGRAPHIC ADDRESSES are: EDITOR of the *British Medical Journal*, *Aitology Westcent*, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent*, London. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

## QUERIES AND ANSWERS.

LEAKAGE AFTER OPERATION ON THE BLADDER.  
DR. ALFRED MERRIN (Kingstown, co. Dublin) asks for help in the following case: A gentleman, aged 80, eighteen months ago was submitted to an operation for prostatectomy, but the prostate could not be removed and he was left with a suprapubic apparatus. A Jacques oesophageal tube, size 18, was threaded through a rubber brick-shaped pad with one end in the bladder and the other in a rubber bag fixed at the thigh. The pad was held in position by a broad abdominal belt. This worked well for a few months and then the fistula began to get smaller; stretching it with sinus forceps and using a smaller tube

answered for a time. At last no tube could be introduced and Dr. Merrin had to enlarge the fistula by a knife, until it took a 24 size. There was no trouble then for another few months, when leakage occurred from the side of the tube. Pads of various shapes have been tried—round, oval, square, hollowed out in the centre, bulged at the place where the leakage seems to occur—but all to no purpose. The leakage is not constant; it always ceases when the patient lies down, and sometimes he may be able to walk and sit about for a few days and keep dry. Varying the length of the tube in the bladder has been tried, with the idea that kinking might occur if too much projected into the bladder. My own view of what has happened (says Dr. Merrin) is that the pad has worn a sort of hollow above the symphysis pubis, the result of months of continual pressure, and that when the old gentleman stands up or sits down the pad rotates and causes a partial occlusion of the tube, with leakage at its side. The pad was dispensed with, but matters got worse. A 22 or 24 tube is used at present and is a very tight fit.

\* \* We have referred this to Mr. R. Ogier Ward, F.R.C.S., who has been good enough to state in reply that the operation of permanent drainage for enlarged prostate is generally successful, and the apparatus described usually keeps the patient quite dry. It is impossible to be sure of the cause of the trouble in this case without seeing the patient. The fault does not lie in the pad, but possibly in the tube, although this does not seem likely, since variations in both length and size have been tried. The other source of trouble is that the sinus is not long enough to make watertight contact with the tube, a matter of technique in performing the operation. All that can be suggested is that the tube be introduced for about 3½ in. Another way to check the length is to palpate the end of it per rectum and then withdraw it slightly. If this fails it is to be feared that nothing short of further operation, either to improve the sinus or to remove the prostate, can put the patient right.

#### INCOME TAX.

##### Motor Car Depreciation Allowance.

"T. F." desires further explanation as to the interaction of the depreciation and renewal allowances.

\* \* It has been held (Caledonian Railway Company v. Banks) that the motor car depreciation and renewal allowances cannot be granted concurrently, but under Rule 6 of Cases I and II, Schedule D, as extended recently to professions, depreciation allowance and "obsolescence" allowance can both be claimed. For practical purposes the difference between the latter allowance and the renewal allowance are (1) that obsolescence applies only where the car has ceased to be suitable for the purpose to be served (this may generally be presumed), and (2) that there should be added to the amount received for the sale of the displaced car the total amount of any depreciation allowances which have been given for income tax purposes in respect of that car. The depreciation allowance is correctly calculated on the basis of the written-down value as at the commencement of the year. In several cases that have come to our notice 20 per cent. has been taken as the basis, but the rate would presumably vary with the type of car—the better the construction the longer it will be fit for professional use, and therefore the smaller will be the appropriate percentage allowance. The annual depreciation allowance is valuable as giving something at once, but it is important to bear in mind that the obsolescence allowance is the ultimate remedy. If "T. F." temporarily loses the £75 allowance for 1925-26 he will pick it up again when he makes his obsolescence claim on his present car. We regard the inspector's action in refusing the £75 allowance for that year as unusual; "T. F." has, we believe, a valid title to it, but it might necessitate the loss of the renewal allowance, and it is perhaps best to accept the position, looking to the obsolescence claim to rectify the matter in the long run.

#### LETTERS, NOTES, ETC.

##### DRUG ADDICTS.

DR. A. G. WINTER (Crowborough) writes: I see we are to be subjected to more vexatious laws governing the administration of "dangerous drugs." Plain men like myself want to know where the drug addicts are that call for such measures. I have never seen a case in general practice: my partner has never seen one; more than that, a very eminent London neurologist whom I met in consultation told me he had been asking general practitioners their experience of such cases for two years—and none of them had ever seen one!

##### MENTAL IRRITABILITY AND BREAKDOWN IN THE TROPICS.

DR. V. D. WYBORN (Federated Malay States), after experience in several countries in the East having widely differing climatic conditions and environments, has formed the opinion that mental irritability and breakdown is due solely to a psychological cause, that of a "lack of associations." He writes: A person removed from his native surroundings, to which his mentality is adjusted, to a new environment, whether tropical or polar, will suffer

until new and mentally satisfactory associations and mental adjustments have dealt with the change. This may or may not occur, depending primarily upon his mental condition as judged from infancy upwards. All physical causes, such as heat, light, and glare, are merely aggravating agents, and are not to be confused with this, the prime cause of the trouble.

DR. T. A. G. HUDSON (Nakachari, Assam), in the course of a letter on the subject, writes: My observations have all pointed to the fact that it is work per se which is responsible for irritability of temperament. A man decides to make the tropics his home, either for a long spell or a short one—and I would emphasize that a short spell means at least three years. He comes out to new conditions of life in all its phases, and it is easy to picture that man trying, during his probation spell, to increase the output of the work done by the natives under him, and the result. In all cases, I might say, no physical or mental effort on the part of the newcomer will influence the native, who still regards him with suspicion. . . . I would urge that all Britishers who are domiciled in the tropics should, in addition to their home leave, have at least a fortnight's complete rest and change locally every year. I have considered mental irritability and breakdown as they arise without any pathological cause, or as they may be finally responsible for pathological changes.

DR. J. M. MACPHAIL (Middlesbrough) writes: With reference to mental irritability and breakdown in the tropics, I am surprised at the scant attention paid to the problem of colour: are the invalids dark or fair, and in what proportion? In England there is an impression that the fair people are dying off and are being replaced by the darker people, who are probably more akin to the original inhabitants. This tendency seems more marked in the large towns. Do not fair people (he asks) suffer more from the attacks of fleas, etc., and are they not more liable to tuberculosis? How do they compare in their reaction to drugs, and to prolonged direct or indirect sunlight? But (he continues) who are the fair? The average man finds in the hair no certain guide, and it is necessary to bring into review the colour of the skin, eyes, eyebrows, and moustache, as men may have indistinguishable or darkish hair, with very blue eyes, and fair eyebrows and moustache. This side of the problem may be of interest, and, in any case, it bears an interest of its own.

##### MEDICO-HISTORICAL POSTCARDS.

AMONG its issue of "old Ashmolean postcards," the Oxford University Press has included a history of medicine series. No. 30, reproduced in colours, represents an amputation scene from a window in the Bodleian, dated 1660. No. 71 shows a Zodiac man illustrating the application of the twelve signs of the Zodiac to the principal regions of the body. No. 72 is an anatomical diagram of the fourteenth century, given by Ashmole to his museum. No. 73 depicts the human brain and the recently discovered "circle of Willis"; it is one of several anatomical drawings made by "C. Wren of Wadham College; 1664." No. 74 is from a diagram of 1631, representing a sick man in bed being besieged by microbes from the four quarters. The walls of his Castle of Health are still secure against the attack from east, south, and west, but the northern bastion has been breached by microbes from the icy regions, which are swarming round the invalid. A physician is feeling his patient's pulse and is holding up a vessel that looks like the urine glass used in uroscopy. The price of this interesting packet of postcards is 6d.

##### A MEDICAL TREATISE FOR NON-MEDICAL MISSIONARIES.

REFERRING to medical missionary work in Africa, as described in a recent issue of the *International Review of Missions*, it was mentioned (BRITISH MEDICAL JOURNAL, July 31st, 1926, p. 212) that one of the contributors to the *Review*, Dr. F. H. J. Lerrigo, had suggested that a special medical treatise for the use of non-medical missionaries should be prepared by a committee of medical practitioners with a knowledge of the special requirements of the entire African field. We have received a letter from Messrs. John Bale, Sons and Danielsson, Ltd., stating that they publish a *Manual of Tropical Disease and Hygiene for Missionaries* by Drs. E. A. and T. Miller Nentby (1923), price 12s. 6d. net.

##### "THE MEDICAL DIRECTORY."

THE editors of the *Medical Directory* ask us to state that the annual circular has been posted to each member of the medical profession, and that they will be grateful for its return by an early post. If the form has not been received a duplicate will be sent on a request addressed to 7, Great Marlborough Street, London, W.1.

##### THE ANNUAL DINNER: CORRECTION.

IN the report of Sir Berkeley Moynihan's speech at the annual dinner at Nottingham (SUPPLEMENT, July 31st, p. 92) reference is made to Dr. H. N. Anderson. This is a mistake; the old friend to whom Sir Berkeley alluded was Mr. A. R. Anderson, C.B.E., late senior surgeon to the General Hospital, Nottingham, now retired and living at Bournemouth.

##### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 40, 41, 44, and 45 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 42 and 43.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 132.

# A British Medical Association Lecture ON DANGERS ASSOCIATED WITH MEDICAL PRACTICE AND HOW TO AVOID THEM.\*

BY  
W. E. HEMPSON,  
SOLICITOR TO THE BRITISH MEDICAL ASSOCIATION.

THE title of my lecture is of your own selection. It covers a wide field, which extends to and embraces both ethical and legal aspects of medical life and practice, though within the compass of time at my disposal I cannot hope to do more than lightly touch the fringe of either.

The responsibilities which a medical man assumes appear to fall within three distinct categories—to himself and to his profession, to his patients, and to the State. I will analyse them briefly in this order, and will then proceed to ascertain what dangers are attributable to each, the circumstances in which they arise, and the means which are to hand for avoiding them. In doing so it will be my endeavour to avoid legal technicalities.

The most valuable attributes a man may claim to be endowed with are those of sound common sense and breadth of understanding, and a medical man is not to be excepted from this general observation. As a general practitioner he is, within the households of those to whom he stands in the relationship of family doctor, regarded and accepted as guide, philosopher, and friend by those who grow up around him, and his ministrations extend as frequently to alleviation of the cares and worries of the afflicted as to the cure of their bodily ailments. It is in these circumstances that fundamental common sense and knowledge of human nature stand him in greater stead, and contribute more materially to the welfare of the patient, than the most highly cultivated "bedside manner."

I counsel you to beware of false gods and the pursuit of the mirage of illusive attractions which are not to be regarded as orthodox. The necessity for observance of the orthodox obtains in every walk of life, and in none is it more urgently needed than in the medical profession.

I read with interest and approval a leading article in the *Times* of March 4th, headed "Doctors and the public," and should wish to adopt as my own sentiments the following paragraph which I extract from it:

"To contend . . . that the public interest can possibly be served by exempting anyone who is to enjoy the status of a registered medical practitioner, from training in those sciences by means of which alone a diagnosis of disease can be made, is on the face of it ridiculous. There can be no 'backdoor' to the *Medical Register*. Nor can the public suffer for a moment any depletion by doctors of their right to determine the nature of a patient's complaint."

Of late years there have sprung up many new cults, such as osteopathy, chiropractic, Abramsism, and Eddyism, which have led to much discussion not free from controversy. Such lures as they may possess are to be avoided by the self-respecting practitioner as presenting features which may tend to imperil his good name and professional reputation.

I feel it incumbent upon me to accentuate this, as I was present not long ago at a medical gathering at which a paper on Christian Science teaching and faith healing was under discussion. The laxity of views then expressed by certain members was a revelation to me, and I did not mince my words in the whole-hearted condemnation which I bestowed upon them. It is playing with fire to flirt with unorthodox practices of the nature indicated, and plain speech on the subject must therefore not be resented.

A few years ago I was retained to represent the relatives of a man who died a death of lingering agony under Christian Science treatment when operative measures would most certainly have relieved his sufferings, if not actually have effected a cure. I was successful in obtaining the committal of the healer for manslaughter; and let it be

remembered that the man who had been drawn into the mesh was a member of your own profession. The path of professional rectitude is the only safe one to travel if you desire to retain your self-respect and be accounted a man of accepted position within your profession.

Consider what are the assets which a medical man can claim. In my conception they lie in his professional good name and reputation, and the preservation of them unsullied should be and must be, in the case of every self-respecting man, his lifelong endeavour. It is well written:

"This above all—to thine own self be true;  
And it must follow, as the night the day,  
Thou canst not then be false to any man."

You will perhaps ask me where guiding light to the uninitiated is to be found in these matters, and my short reply is—by reading the *BRITISH MEDICAL JOURNAL* and studying the transactions of the British Medical Association. Assistance upon every phase of ethics and ethical teaching is to be obtained through that body, and the annual *Handbook* issued by the Association should be in the consulting room of every practitioner. A new and enlarged edition of this work is in the course of preparation; it will contain material of inestimable value to every practitioner, be he newly qualified or of many years' standing.

It is, moreover, to be borne in mind that no one is turned down who applies to the Association for advice in circumstances of either doubt or difficulty, and special facilities are afforded to those who have but recently entered the profession.

I cannot refrain from quoting the following passage, which recently caught my eye in a leading article in the *Medical Journal of Australia* dealing with the position of the Association in regard to the medical profession.

"To-day the British Medical Association is stronger, more important, and more firmly established in Australia than ever. No voices are now heard advocating the establishment of an Australian Medical Association. No one wishes to weaken the bond. Just as the Empire encircles the earth and arouses pride in the breast of each and every citizen, the ideals of Charles Hastings have been cherished by British subjects through ninety-three years and awaken the pride of each member of the British Medical Association in the Commonwealth."

It was my privilege five years ago to visit our overseas dominions of Canada, British Columbia, New Zealand, and Australia, and, holding the accredited position which I do with your Association, I was accorded a gratifying welcome wherever I went; it opened my eyes to the power which the Association holds, not only at home, but also throughout His Majesty's dominions beyond the seas. The position in Australia at that time was somewhat unsettled, and through conversations which then took place were of assistance in establishing matters upon a footing which is represented by the sentiments now expressed in the quotation from the *Medical Journal of Australia* which I have just read.

Let me warn you against the practices of fee-sharing and accepting commissions. Any principle of fee-sharing and dichotomy, as it is called, is only to be permitted within the terms of a partnership arrangement or in circumstances where one medical man acts for or assists another. The accepting of commissions from life insurance companies, manufacturers, or under like trade conditions, does not conduce to the dignity of the medical man, nor can it be done without the possibility of danger.

Associations of the nature of partnerships are frequently entered into light-heartedly by members of the profession. I regard them, in the light of many years' experience, with a much more serious eye. They assume to me the character of a business marriage, in which, if it be possible, a preliminary courtship is eminently desirable. I have now been associated with medico-legal work for something like thirty-five years, and during that period many hundreds of cases of partnership disputes have come under my consideration; this shows that more thought bestowed upon the arrangement prior to its being entered into and cemented would have avoided much trouble.

The responsibilities of a medical man towards his patients, regarded from a legal standpoint, were aptly summarized by a learned judge in the following words:

"Every person who enters into a learned profession undertakes to bring to the exercise of it a reasonable degree of care and skill. He does not undertake, if he is a surgeon, that he will

\* Delivered at Leicester, March 26th, 1926.

perform a cure, nor does he undertake to use the highest possible degree of skill. There may be persons who have higher education and greater advantages than he has, but he undertakes to bring a fair, reasonable and competent degree of skill, and the question which always arises is whether the injury must be referred to the want of a proper degree of skill and care in the person whose conduct is sought to be impeached."

This may be taken as the standard which has to be established to the satisfaction of a jury in any case in which a medical man is sought to be mulcted in damages in an action for malpraxis.

The arrangement between a medical man and his patient has for its foundation and basis that of "contract." On the one hand, the patient who retains the services of a medical man undertakes to pay his proper fees for treatment received, and the medical man reciprocally undertakes to bring a due and proper meed of skill to bear and to treat the patient with every reasonable care.

Every man is, however, bound to keep himself abreast of matters moving within his profession, and to show reasonable knowledge concerning them and the application of them in relief of the ailments he is called upon to diagnose and treat.

The obligations of a medical man to the State arise under the head of criminal liability for negligence, and the following extracts from the dicta of learned judges will suffice to make the position clear in this respect.

"Where death is occasioned by negligence on the part of anyone professing to deal with the health of others whether he be a licensed practitioner or not the offence may, under certain circumstances, indicating a wanton and malicious disregard of human life, amount to murder. Of course a medical practitioner who should intentionally and with malice cause the death of a patient would be held guilty of this crime, but in no case will an indictment for murder lie unless there be a felonious destruction of life with malice either expressed or implied. The law holds, however, that every person, whether licensed or unlicensed, who deals with the life or health of any of His Majesty's subjects, is bound to have and to use competent skill, and sufficient attention, and that if the patient die for want of either the person is guilty of manslaughter."

The late Lord Ellenborough expressed himself as follows:

"To make out a case of manslaughter, the prisoner must have been guilty of criminal misconduct arising either from the grossest ignorance or the most criminal inattention."

You have thus before you a brief summary of the obligations and responsibilities which devolve upon a medical man under the three heads embraced within this address, and we may now examine more closely the dangers resulting from the non-observance of them.

To keep within the true and proper standard of ethics secures for you, not only a professional recognition which is worth having lived for, but it inculcates within you a sense of rectitude and pride which is a man's truest guide to right conclusions in matters of doubt or difficulty. Such is the influence so far as both mind and matter are concerned. Deviation from this true course is sure to bring trouble in its wake, with professional penalties or opprobrium attaching which leave their mark upon the reputation of the individual concerned. It is, moreover, to be borne in mind that the memory of quality, be it of services rendered or articles of commerce, remains long after the price is forgotten.

To your credit be it said that in no profession is the standard of ethics higher than your own, and in none is the teaching upon it more clearly laid down than is to be found through the sources which I have already indicated. It is therefore for you to read, mark, learn, and inwardly digest what you have at hand to guide you, and follow the true course thus mapped out for you.

You will, I feel, look for a word from me on the subject of the General Medical Council, against which so violent a storm of public criticism has been directed during the past few months. It has been my privilege to plead before that body for more years than I care to count, and I can personally vouch for the even-handed justice which is meted out to all who come before it as respondents. The Council is invested with statutory powers necessary for the preservation of self-respecting action and discipline within the profession, and anyone who flagrantly contravenes either cannot complain if, in the review of such conduct,

an appropriate measure of censure or penalty, as the case may be, is visited upon him. An able exposition of the "Constitution, functions, and procedure" of the General Medical Council, by Mr. Norman King, the Registrar, was published in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL of March 20th (p. 96). I trust that it will be widely read, and that the foolish misconceptions which appear to be so prevalent, together with the unmerited prejudice which has been created as arising out of them may be thereby removed.

The measure of responsibility of a medical man toward his patient has already been defined, and so long as the standard thus established is conformed to he is rendered free from legal responsibility in point of damages or otherwise.

It is, however, to be recognized that the medical profession is peculiarly open to attack in two particular respects—namely, so far as actions for malpraxis are concerned, and with relation to imputations upon the practitioner's professional good name and reputation.

My experience points to the conclusion that of all professional men the medical man is the one most popularly selected for speculative actions. The explanation may be the ease with which the decision of or the treatment by a medical man can be impeached owing to there being no actual fixed science in either medicine or surgery, and to the further fact that, proverbially, "doctors differ."

There are, moreover, unfortunately, within my own profession ready sources available for fostering litigation on terms of easy recompense if the would-be litigant is a person of limited pecuniary resources. Nothing is easier than to attack a medical man on the ground that he has inaccurately or imperfectly diagnosed a particular case, or that, having correctly diagnosed it, he has improperly treated it, or, in the case of an injury by fracture or otherwise, that he has failed to appreciate the severity of the injury, or, having correctly diagnosed it, has failed to apply to it modern and skilled recognized surgery. With people of the class who are responsible for actions of this nature it would seem that anyone's opinion is better than that of the medical man involved.

It is also to be found that little difficulty is experienced within the ranks of the medical profession itself in obtaining evidence whereby to give some shadow of support to the allegations of negligence or incompetence which are preferred. With every allowance made for difference of opinion, it is important—and I should have thought embarrassing—to the profession to find it accentuated to such a degree that, in certain instances to which I can speak, medical men in equal numbers have appeared in open court before judge and jury, of whom one half gave evidence in approval and the other half in condemnation of the treatment or diagnosis by one of their colleagues.

The medical man also incurs a risk, pregnant with danger to reputation, arising out of slanderous attacks upon his professional good name, knowledge, and skill, in circumstances similar to those which prevail in malpraxis actions. A patient, burning under the secret grievance of alleged incompetence or unskilful medical treatment, takes every opportunity of sharing his views on the subject with his friends and neighbours, and the ball thus set rolling increases in magnitude as it travels, until the medical man whose diagnosis or treatment is thus brought into question finds himself the object of unenviable notoriety, the cause of which, in many instances, it may be extremely difficult for him to trace. There is truth in the saying that "Scandal is like an egg—when it is hatched it has wings." We shall, I think, also be unanimous in our agreement with Socrates that thanks are due to the Creator for having invested the human subject with two eyes, two ears, but only one tongue.

As practical evidence in illustration, I may inform you that during one period of fifteen years, in which 2,467 cases were referred to me by the Medical Defence Union, nearly 500 involved the defence of members of the profession in actions for damages founded upon allegations of want of care and skill in the treatment of their patients, and nearly 800 had relation to libel and slander actions either prosecuted or defended on behalf of medical men.

To my mind the realization of the risks to the profession in the two respects I have mentioned led to the formation in 1885 of the Medical Defence Union, which I believe to have been the pioneer society in this protective movement. Do not fail to observe and do not ignore the danger signal which is ever present in these cases. Some complaint in regard to the account rendered, with a carefully veiled innuendo that the patient had not made satisfactory progress or recovery, is usually to be found as the starting-point, or alternatively a suggestion that, if some other remedy than that prescribed had been resorted to, better results would have been obtained. There are various methods of wrapping it up so as to obscure the hidden poison, but, rest assured, it is there right enough, and needs to be dealt with strongly and diplomatically. Do not allow a communication of this nature to "lie on the table"—it marks a falling barometer as a prelude to trouble brewing. If you experience doubt or difficulty as to the manner in which it should be dealt with, then seek advice on the subject through those channels of knowledge and experience which are open to you. If you elect to sit under imputations upon either your professional honour or your skill, take it from me that you are heading for trouble.

One further point which flows from this advice must also be accentuated—namely, "beware of compromise." I say unreservedly and in all seriousness that nothing can be more disastrous. The admissions to be read into this procedure are in every respect prejudicial to reputation, and form but the prelude to further embarrassment in the future. If time permitted I could give hundreds of instances, within my own experience, in which the truth of these sentiments has been borne out.

If your account for services rendered is impeached on the ground that you did not give value for money, your duty to yourself and to your profession is to enforce payment of it through the proper legal channels. By the same token, if your patient, or his or her near relatives, impugn your treatment, insist upon a full and complete withdrawal of such allegations, and refuse to continue further to attend them if this be not forthcoming.

I am convinced that if this high standard of thought and action which I advocate were uniformly observed throughout the profession, fewer cases of actions savouring of thinly veiled blackmail would be heard in our courts. Let me give one instance in point, so as to drive the matter home.

My client, a member of your profession, was threatened with an action for damages arising out of his alleged unskillful treatment of a patient. Left to himself he would have settled it on any terms within the compass of his means as he dreaded the publicity which would follow upon its being heard in court. To this I absolutely refused to be a party. The solicitor acting for the claimant came and saw me, having travelled some 200 miles to do so. He opened with an offer to accept £100 and his costs, coming down by gradations to his travelling expenses to London, which I incontinently refused. He left much chagrined, and did not trouble me further.

But now comes the tribute—a brother professional friend of this solicitor was placed in similar case with regard to another medical man whom he purposed suing, and, meeting him and hearing the facts, my friend gave him this salutary advice: "If you are up against Hempson, drop it—you'll get nothing out of him; I've tried it myself, and it is worse than kicking a stone wall." Forgive the egoism with which this story is tinged, and you will, I think, agree that good service resulted to the profession due to my hardness of heart.

No one, whatever his professional status or reputation may be, is immune from risk in regard to these two particular classes of action. They occur in circumstances wholly unlooked for, and are not infrequently associated with cases in which the medical man concerned has felt cause to congratulate himself on the results attained. One example I quote, fertile both in its unlikelihood of occurrence and in its baseness of ingratitude.

A medical man who was going away for a couple of days was driven to the station by his groom, who, on the return journey, took the opportunity of getting drunk. As a result he had a bad spill, was thrown out of the trap and was trampled on by the

horse, sustaining a compound comminuted fracture of the right ulna and radius. His arm was temporarily put up at a local hospital and the man got home, the damage to horse and trap representing a loss to his employer of some £50 or £60.

Instead of dismissing him and leaving him to his own devices, the doctor generously retained the man in his employ for three months and gratuitously treated him during that period. Owing to the severity of the injuries sustained, a false joint resulted, with consequent impaired use of the limb. On these facts an action was launched in which damages to the amount of £500 were claimed, based upon allegations of wrongful and negligent treatment leading to loss of full use of the arm.

The late Sir William Thorburn of Manchester finished off the case for us with judge and jury in the evidence which he gave on behalf of the doctor concerned. He certainly was without exception one of the best witnesses I ever called. Under cross-examination by the eminent King's Counsel who had been briefed for the plaintiff he admitted—apparently with reluctance—that he did not agree in all respects with the doctor's treatment of the case. This was, of course, joyfully welcomed, and he was pressed to state fully and explicitly to his lordship and the jury the grounds of this difference. This he did in the most dramatic manner by emphatically stating:

"Dr. X was too humane, he tried to save the arm—I should not have done so—I should have amputated."

Judge, jury, and I think everyone else in court, except the King's Counsel, who was caught napping, rocked with laughter, and the jury then and there declined to hear any further evidence, and gave a verdict for the doctor, which was recorded with costs as against the groom.

This was satisfactory to the doctor, you will say, and yet from one point of view what a farce a verdict of this nature is—namely, so far as "costs" are concerned. In this case the expenses incurred in defence of the doctor were certainly not less than £250, and the groom had not a five-pound note in the world to bless himself with.

Therefore, left to your own resources, it comes to this—namely, that if attacked as this doctor was you have to be prepared to deplete your pocket to the amount I have indicated in vindication of your professional reputation as a self-respecting member of an honourable profession.

Even more apt in illustration of this lamentable phase of matters is to be found in the action of "Vonn v. Todesco and Elder," which has been before the courts within the last few weeks, and is fully reported in the *Times*. It was being tried for the second time, as the jury at the first trial disagreed.

At this second trial the judge, Mr. Justice McCardie, directed the jury as follows:

"If doctors were to be held liable on the documents and testimony which was before them, then no doctor would be safe." He moreover stated in explicit terms that: "He had formed the conclusion on the evidence before the court that the defendants ought not to be held liable." Notwithstanding this, the jury again failed to agree on the merits of the case, and were discharged without giving a verdict, certain technical legal points being reserved for further consideration.

This was an action brought under the orders of the court relating to poor persons, from which it follows that, win or lose, neither of the doctors concerned could hope to recover anything in point of costs, and yet the expenses incurred in their defence in these two trials must have been at least £600 to £700.

I much doubt whether many of you appreciate the value which lies in taking and preserving notes of your patient's cases, thereby recording the treatment prescribed or recommended and refused, as the case may be. The observance of this simple precaution has won many a lawsuit which otherwise might have been lost. I shall probably be told that the general practitioner has not time for this sort of thing, but I can only point out to you the road of prudence and protection, leaving it to you to decide as to the wisdom of following the advice given.

The responsibilities of a medical man to the State are for criminal negligence, the definition of which I have already given.

Civil liability for neglect lies in the failure to exercise reasonable care and skill, whilst gross ignorance or criminal inattention are necessary incidents to support a charge of manslaughter, and a wanton and malicious disregard of human life in the treatment of a patient have been held to amount to murder.

The minds of the profession were seriously disturbed about twelve months ago by the criminal prosecution of Dr. Hadwen of Gloucester arising out of his treatment of a child for diphtheria. Had this resulted in a conviction

it would, indeed, have been a serious thing for the profession, but I predicted from the first that, in the circumstances of the case as I knew them, this was impossible without perilously straining the law, and I therefore confidently anticipated the acquittal which resulted. Personally, I strongly hold the view that it was a case in which the criminal law should never have been put in force.

Another recent case was that of Dr. Percy Bateman, resulting from his treatment of a woman in confinement, and the judgement in his favour delivered by the Court of Criminal Appeal forms a valuable contribution to the law on this highly important phase of professional life.

It must not be thought that I have painted the picture I have presented in too vivid colours; I have endeavoured to confine myself within the limits of moderation based upon those matters which are with me the subject of daily observation, and have been so for nearly thirty-five years. That you as medical men undertake those legal responsibilities which I have outlined is clear, and that you are required to discharge them towards your patients and the State within the limits and to the extent I have shown is equally clear.

*It remains for me to give you some guiding light as to protecting yourselves from those legal risks which I have accentuated.*

I know of only one source through which this can be done efficiently and economically—namely, by securing membership of one of the defence societies immediately after you have registered. Outside this protection a man stands alone, never knowing when or in what circumstances his treatment of a case may be impeached, or the extent to which such an impeachment may be carried. The subscription to any one of these societies should be within the competence of all, and it is a species of insurance which no prudent man should neglect.

The material benefits to be secured are financially great, as a complete indemnity from any expense is to be obtained whether the action be wholly successful or otherwise. Outside this there are other benefits which flow from membership which are perhaps not sufficiently appreciated.

First and foremost is peace of mind and absence of apprehension arising from the knowledge that you are thus protected. This sense of security is extended by the further knowledge that in the event of any complaint which conveys merely a sense of dissatisfaction of treatment received, you have the society at hand to guide you as to the most prudent course of action to adopt, and you have the further knowledge that a wholesome respect is entertained by all would-be litigants as to the thorough manner in which these cases are dealt with, and which does not extend to the medical man himself and his private advisers.

An address of this nature cannot be closed without giving expression to one reflection which inevitably occurs to the mind—namely, the immense amount of work which is done gratuitously by every medical man, and the small meed of gratitude which is shown in return.

I say with confidence and without fear of contradiction that in no other walk of life is there to be found an example of equal merit than that which the medical profession has set.

Take the hospitals throughout the length and breadth of the world, with their honorary and consulting staffs giving yeoman service of their best in the alleviation and cure of disease, but nevertheless the same responsibilities attaching as pertain to general private practice. Do not disguise from yourselves the fact that the law does not afford relief from liability on the ground that the services of which complaint may be made were voluntarily given, and it is the physician or surgeon (as the case may be) who is personally responsible for the acts which he performs, and for the due and proper discharge of the duties of those who are assisting him.

The high ideals by which your profession is animated are aptly conveyed in the words of Lord Dawson of Penn: "The medical profession are actuated by singleness of purpose, and try to keep aglow the lamps of science and service to lighten the path of public welfare."

I commend these sentiments to your keeping.

## British Medical Association.

### PROCEEDINGS OF SECTIONS AT THE ANNUAL MEETING, NOTTINGHAM, 1926.

#### SECTION OF DERMATOLOGY.

H. G. ADAMSON, M.D., F.R.C.P., President.

#### DISCUSSION ON ECZEMA.

##### OPENING PAPER

BY

ARTHUR WHITFIELD, M.D., F.R.C.P. LOND.,

Physician in Charge of Skin Department, King's College Hospital and Professor of Dermatology, King's College, London.

I should like first to thank the Committee of this Section and especially my old friend the President, for the honour they have done me in inviting me to open a discussion of eczema, for if we disagree on every other point I feel confident we shall be united in considering it the most important subject in the whole of dermatology.

It appears to me that in any discussion of this kind it is important to find some base from which to start upon our various paths, and if we can find as our base some definite condition which we all agree to be invariably present in eczema I think we shall help the clarity of the subsequent discussion. Now the attempt to find this base has been an object of search with me for many years, as it has been of course, with several others. One could attempt to define eczema purely from the etiological standpoint, but this is to assume at once that it is a specific disease in the sense that tuberculosis and syphilis are diseases. Next, we may take up the clinical manifestations of eczema. These are at first sight somewhat multiform, but if we include with the clinical manifestations the appearances in microscopic sections which we can associate with those that we observe with the unaided eye or with the hand lens I believe we can find what I may call an elementary lesion which is always present, though in varying stages of development. Thirdly, we may be guided by the physiological state of the skin, taking into consideration its vasomotor stability, and its reactions to various stimulants.

We thus have before us three standpoints on which to base our definition—namely, the etiological, the anatomical and the physiological. Of these three I propose to discard the first, because if eczema is a disease of multiple causation it is obvious that cause cannot be used for defining purposes, and if it is a disease due to a single cause then we are in entire ignorance of the nature of that cause and again we cannot make use of it for definition. This leaves us with the anatomical and physiological grounds and with these combined I think we can construct some sort of a conception which may command a general if not a unanimous agreement.

##### *Anatomical Considerations.*

As far as my knowledge goes it is to the acute observation of Willan, as quoted by Bateman, that we owe the anatomical conception of eczema, and I believe that we shall find a reasonable unanimity on one point. This is that although some may claim that Willan's clinical characteristics are found in conditions to which they would refuse the term of eczema, all will agree that they are certainly found in eczema.

Now Willan described the essential lesion of eczema as a small vesicle of the size of a pin's head, many such vesicles being crowded together, with little or no inflammation round their bases, and unattended by fever. He stated that the disease was not contagious. Since he attributed different varieties to different causes (eczema solar from the sun; eczema impetiginoides from various chemical irritants—sugar, lime, Indian varnish, etc.; eczema rubrum from mercury and other causes), it is obvious that what he had in mind was not a disease in the sense of an etiological entity, but a condition varying in severity yet always founded on his primitive vesicle and called forth

by many causes. I would draw special attention to the fact that his description implies that these vesicles do not enlarge, since he describes them as forming "a brownish-yellow scab of the size of a pin's head."

Here, then, we have an admirable description of the clinical conditions to be found on careful examination with the naked eye alone or with the aid of the simple lens. By the aid of serial microscopic sections we can now see how accurate this description was and how the condition is brought about.

The earliest lesion is a congestion of the capillary loop in the head of a single papilla followed by exudation of lymph from this vessel. This works its way through the epidermis from the base upwards, at first causing a localized swelling by distension of the intercellular channels (the eczema papule), then forming a deep-seated vesicle in the middle of the stratum mucosum by rupture of the intercellular fibrils, and finally working its way up to a position immediately below the horny layer with the formation of the obvious translucent vesicle of Willan. During all of these stages in the acute disease proliferation of histiocytes is slight and leucocytosis of the polynuclear variety absent. The lesion is microscopically and, as far as can be determined, culturally non-bacterial.

I have gone into some detail over these points because I want to build a little further on this conception. This deals adequately with the acute form, but what about the chronic forms of eruption to which we still give the name of eczema?

It is obvious that at any stage the further development of the lesion may be checked. The congestion may be chronic but not intense, exudation may be slight, causing some thickening by oedema over the papilla head (spongiosis), but never becoming sufficiently intense to rupture the interepithelial fibrils and produce a frank vesicle. There will, then, be a sheet of these small papules with some thickening due to overgrowth of the epithelium (acanthosis), accompanied by disturbance of the keratin function and secondary scaling (parakeratosis). Such cases are generally called forth by local traumatism, and when infected with pyogenic organisms the infection is a secondary consequence of the disturbance of the horny layer combined with scratching and inoculation. Willan's conception thus still holds true, even in the more chronic forms, though the lesion may not be obvious to the naked eye. For those forms of pyogenic dermatitis which do not show the fundamental papule or vesicle I would prefer not to use the term "eczema" at all, though this would entail some alteration of our nomenclature.

Such, then, is the anatomical part of the definition of eczema which we are trying to construct, and I turn now to the physiological state of the skin in eczema.

#### *Physiological Considerations.*

When we view the ready congestion of the capillary loop in the head of the papilla and its consecutive exudation of lymph from it into the papilla and overlying epidermis and the oedema of the pars papillaris generally, we see at once that these two reactions must be called forth by some stimulus—that is, the papule or vesicle is the anatomical expression of a physiological reaction to irritation (I am using physiological to include both normal and morbid processes).

In this connexion I consider we owe a great deal to Jadassohn, who analysed the reactions of the skin to various agents in a very careful manner. It would take too long to detail his rather elaborate thesis, but I may remind you briefly that, compared with the normally reacting skin, he recognized, first, skins with either a special susceptibility to one irritant so that they reacted to very small doses, or a general susceptibility where the reaction was present to many such bodies; secondly, skins with an idiosyncrasy reacting to minute doses of bodies which to most skins could not be classed as irritants at all. This idiosyncrasy may be shared by a large number of skins in the case of certain bodies, such as *Rhus* and *Primula elatensis*, or may be very exceptional, as, for instance, in a patient of mine, who suffered from eczema on approximation to Malmesbury carnations.

Recent American observers have maintained that, at any

rate in the case of *Rhus*, complete immunity does not obtain, and if this prove to be true not only of *Rhus* but other "idiosyncratic" bodies it impairs the validity of Jadassohn's separation of susceptibility from idiosyncrasy. Nevertheless, as a working hypothesis I think it may be allowed to stand, since the difference between the two types is certainly marked.

What I think we shall all be agreed upon is the fact that exposure to various external agencies will call forth eczema in the suitable patient when it would not do so in the normal individual. That is to say, that in eczema there is a special or general irritability of the skin which we may call in general terms a susceptibility. If we accept this statement as true, and also admit that this susceptibility may be exhibited almost from birth or may develop later in life, we have, I think, all that we can at present obtain for the construction of our definition. This will then run as follows:

"Eczema is an eruption consisting of oedematous papules and vesicles arising in the deeper part of the epidermis and caused by an abnormal susceptibility, congenital or acquired, to the action of external irritants."

I am hoping that what I have already said will not meet with much opposition from those who have devoted close attention to the study of eczema, and this hope is inspired by my belief that the chief point of dispute relates to the importance of constitutional states in the production of eczema.

#### *The Constitutional Factor.*

If I may trespass on your patience for a few more moments I will endeavour to put before you my views of the constitutional factor in the etiology.

As a form of introduction I will draw your attention to a frequent complication of varicose eczema. I may say that I regard varicose eczema as a mixed pyogenic dermatitis on an irritable basis—that is, that it is a hybrid eruption.

It is a quite common thing to come across such a case as this, chiefly in hospital practice. A patient is seen with a recent papulo-vesicular eczema of the arms, extending perhaps to the neck. The eruption is a typical eczema of the scattered variety, showing no particular figurate arrangement or marginal limitation and spread. On seeking for the etiology one finds that there is present in one leg a chronic patch of varicose eczema of long duration. Owing to some recent adverse condition, which may well be an unsuitable local application, the chronic patch has been excited into a more active state. Shortly after this occurrence the rash on the arms has supervened, this rash having, clinically at all events, no similarity with the marginate infection or infected dermatitis, which we dismiss as septic eczema or dermatitis, according to our fancy.

Now in such cases I have repeatedly performed the experiment of treating the patch on the leg to the best of my ability and leaving the eruption on the arms alone, merely explaining to the patient that it will die away untreated, and when I have been successful with the patch on the leg the prophecy has come true.

It seems to me, therefore, that something occurs in the chronic patch which produces the generalized eruption. This might well be either a nervous action, a spreading of irritability from the local patch to the whole cutaneous surface, or a generalized cutaneous intoxication by the absorption of some poison generated at the local patch; or, again, it might be due to a combination of the two processes.

In this connexion I would remind you of two facts. First, that many years ago Bockhart, Bender, and Gerlach found that they could not induce eczema by rubbing live staphylococci into the skin if these were washed, but that they could do so by using the culture filtrate without any organisms; secondly, that Professor Arthur Hall, who has done so much excellent work in the investigation of the etiology of eczema, was unable to cause a generalized eczema in a girl by the local application of the irritant from imitation pearl beads to which she was susceptible. In this instance I must admit that Professor Hall thought he might have been successful had he gone on longer, but

the local inflammation was so severe that the patient refused to submit to further experiment.

It would appear to me, therefore, that there is rather more evidence in favour of the toxic theory. Further in favour of the toxic theory I will refer for one moment to cases of food poisoning. I suppose that we all recognize two forms: first, the frank urticaria, where the chief change is in the deeper part of the corium and sometimes even in the subcutaneous tissue, and a second type characterized by the presence of minute papules, generally follicular in situation, scattered thickly over the body and limbs, and not so evanescent. This second type lies mostly in the papillary body, and is succeeded by desquamation. If rubbed, as it generally is, it develops rapidly into a vesicular eczema, needing only the slightest trauma to do so. I suggest to you that this is the result of some bacterial poisoning absorbed from the intestinal canal, and is analogous to the generalization from the pyogenic varicose dermatitis referred to above. If this idea be correct, it would, of course, account for the association of eczema with focal sepsis, on which so much stress has been laid by some observers.

We may conceive, then, that there is one type of toxin which acts on the deeper vessels and nerves of the corium in such a way that the slightest rubbing or pressure determines the development of an urticarial wheal, whereas another type so affects the epidermo-papillary system that by the same kind of local stimulus an eczematous reaction is produced. If we accept this theory then I think we can explain those cases in which mental anxiety or shock seem to be active in helping to produce eczema by supposing that digestive disturbance, errors of gastro-intestinal motility and secretion, result in erroneous chemical cleavage of the food, whether bacterial or otherwise, with the production of an alimentary poison of the same type as that present in food which is decomposed before ingestion.

#### "Seborrhoeic Eczema."

Before concluding this somewhat sketchy survey it is, I think, necessary to refer as shortly as I can to that terrible bone of contention "seborrhoeic eczema" or "seborrhoeic dermatitis"—the idol of some and the bugbear of others.

Dealing first with the simplest form—the dry micaceous scurfy head—I believe that Sabouraud is quite right in maintaining that this is neither eczema nor seborrhoeic, but a definite infection of the superficial horny layer by the organism commonly known as the "bottle bacillus." Where I think Sabouraud was too limited in his conception is in the fact that, in my opinion, he failed to recognize a constitutional side to the question.

We are all exposed to infection with this organism, and most of us are infected, and, further, the infection in any individual varies greatly from time to time.

It is now some years since I first learned from a patient who was susceptible to "hay fever," and also had an idiosyncrasy to strawberries, that there was another factor besides the mere infection with the bottle bacillus. This patient had at most seasons of the year an only slightly scurfy head, but during the grass pollen season she always suffered, if in the country, from hay fever, and during the attack her head became intensely irritable and scurfy, microscopically showing almost purely the bottle bacillus. If she went to sea in her yacht during this season her scalp remained almost clear, but if while at sea she ate strawberries she developed the symptoms of hay fever and the scurfy head, so that it is probable that the scurf was not the result of local irritation of the scalp by the pollen.

Since this time I have collected one or two more cases of patients whose scalps become violently scurfy and irritable when they suffer from hay fever. Some of them always suffer to some extent from scurfy head, whereas in others it is not noticeable except during these exacerbations. This disease I prefer to separate entirely from eczema under the heading of "pityriasis capitis."

Sabouraud has also pointed out that as a complication supervening upon the disorganized horny layer there may ensue an infection with the non-liquefying staphylococcus which he calls the "*Coccus butyricus*." The moment that this secondary infection occurs the histology of the disease

is changed and the hitherto dry scales become mixed up with blocks of dried serum. This is the condition which is so commonly seen in the scalp from puberty onwards.

Now on the body when this double infection takes place it is associated with reddish rings, and has been given all sorts of names: "lichen circumscriptus," "seborrhoea corporis," "seborrhoeic eczema," etc. Microscopical examination shows that it is in reality a combination of a superficial scaling—to use the French term, "epidermitis"—and a low-grade but not entirely aleucocytic folliculitis. It is not, therefore, in my opinion, an eczema any more than tinea circinata is an eczema.

Lastly, there is a third form, commonly seen with a V-shaped distribution over the shoulders and upper back. The lesion here is a discrete spongy papule or abortive vesicle, which may be in places aggregated, but is not arranged to form rings or polycyclical figures. Microscopically I cannot distinguish the lesion in this case from that of simple eczema, except that the oedema is localized rather specially to the mouth of the sweat gland. I therefore believe this form to be a true eczema of chemical origin, the offending chemical being in all probability an irritating fatty acid (butyric acid?) produced by bacterial decomposition of the sweat.

#### Summary.

To sum up my position, then, I will put forward the following view:

Eczema is a clinical condition and not a disease with a single specific cause.

It is the result of irritation of the skin, and is associated with an undue susceptibility.

This susceptibility may be congenital or acquired. When acquired the susceptibility may be the result either of repeated external trauma or a generalized toxæmia of a particular type.

Perhaps I may be allowed, in conclusion, to quote to you some sentences from the preface of Dr. Bateman's incomparable synopsis.

"I am aware, indeed, that there are many individuals, professing themselves to be practical men, who affect a contempt for all nosological disquisitions, and deem the discussions relating to nomenclature, in particular, very idle and frivolous, or at the best, a sort of literary amusement, which is not conducive, in the smallest degree, to the improvement of the medical art. But this I conceive to be a mistaken view of the subject, originating perhaps from indolence, or from a want of habitual precision in the use of language. The inferences of slight and superficial observation may, indeed, be detailed without recourse to a very definite vocabulary; for where little discrimination is exercised very little nicety can be requisite in regard to the import of the language employed.

"But it is not by such means that the boundaries of science are extended."

#### GENERAL DISCUSSION.

Dr. W. Dyson (Manchester) said that eczema was a non-microbial superficial inflammation of the skin, the result of external irritation in a predisposed subject. He divided predisposing causes into two categories—congenital and acquired. They produced a sensitization of the skin, which caused it to react to an irritant which would not produce inflammation in a normal individual. What was the cause which brought about sensitization of the skin? Was it a localized anaphylaxis? In some respects it corresponded to an anaphylactic state, but, so far as was known, anaphylaxis was an absolutely specific reaction to one substance, whereas a sensitized skin would often react to any external stimulus; moreover, a localized sensitization might occur following injury to a portion of the skin, in which predisposition to eczematous outbreaks remained confined to the damaged part and was probably the result of local loss of vitality—a different phenomenon from a generalized sensitization. It was a common occurrence in occupational dermatitis to find the whole skin becoming sensitized and to see areas, untouched by the irritant, the site of a sympathetic dermatitis. Again, a dermatitis might be in the first place a skin reaction to a specific irritant, but subsequently the reaction might cease to be specific, and the skin react to any external stimulant. The speaker made the suggestion that the epithelium was a secretory organ and that at some future date it would be found in function to

be in the same category as the ductless glands. The histological appearances and staining reactions of epithelial cells closely resembled those of other glandular structures. If this could be proved it would help them to understand many of the problems of dermatology of which they were at present ignorant. If this were a fact it would be possible that the epithelium, when irritated, secreted a substance which produced a general anaphylactic state of the whole skin and thus produced a general sensitization. He had found small stimulating doses of x rays the most efficacious method of desensitizing the skin. Might it not be that by this method of treatment they were passing into the circulation small doses of the specific virus which produced the anaphylactic state, and in this way caused an anti-anaphylactic condition of the skin?

Dr. RUPERT HALLAM (Sheffield) thought that all would agree with Dr. Whitfield's view that an abnormal susceptibility to the action of external irritants was present in these patients, but he wondered whether Dr. Whitfield would not also be prepared to admit that an internal or endogenous irritant might sometimes replace the external irritant and cause precisely the same anatomical lesions. Did not the train of circumstances which took place in the case of the varicose ulcer with a secondary dermatitis support this view, and was not this the response of the skin to a toxin carried by the blood stream? Could it not equally well come from some lesion in, say, the alimentary canal? A very interesting case quoted by Schoenhof in 1924 seemed to support this view. The patient was occupied in preparing asparagus for cooking; a dermatitis developed, not only on contact with the vegetables, but also on ingestion of the same. Bloch was able also to produce a dermatitis in a young woman by giving iodide orally, intramuscularly, or by contact with the skin. If this view could be accepted it would help to explain the etiology of many of their cases.

As regards the individual hypersensitiveness, which might apparently be hereditary or acquired, Bloch's pupil Jaeger had performed some interesting experiments. He standardized his irritants by means of plasters containing a definite percentage of various chemical substances, such as formalin, iodoform, or primula juice. These were placed on the skin for a definite time on 1,100 individuals, among whom were 333 patients with eczema. A positive result was obtained in 35 per cent. of the eczematous and in 5.4 per cent. of the healthy. This showed that the eczematous were seven times more sensitive to these irritants than other persons. The greater proportion of positive results were obtained in chronic cases, less in occupation dermatoses and in the so-called seborrhoeic eczema.

Dr. H. W. BARBER (London) endeavoured to distinguish certain clinical types of the eruption with a view to seeing whether it was not possible to deduce the probable cause in a given case from the distribution, configuration, and type of lesion present.

First, as regards "seborrhoeic eczema" he agreed with Dr. Whitfield that seborrhoeic dermatitis was not a true eczema, but an inflammatory reaction of the eczematous type (eczematide of Darier) due to infective organisms, comparable with that produced by a ringworm fungus. But they must all admit that not uncommonly in seborrhoeic patients, particularly in hot weather, an acute true antimicrobial eczematous reaction did occur—for example, on the hands and feet, producing one type of what was formerly called cheiropompholyx. This might be comparable with the third type of "seborrhoeic eczema," referred to by Dr. Whitfield as occurring on the back, which he had suggested might be due to irritation by a fatty acid, such as butyric acid, produced by bacterial decomposition of sweat. But such an eczema—at any rate when it occurred on the palms and soles—was more likely, in the speaker's opinion, to be due to the actual excretion of fatty acids by the sweat glands, as the palmar sweat was always strongly acid in these cases, although sebaceous glands were absent on the palms and soles. This type of eczema might occur in seborrhoeic subjects, apart from any active seborrhoeic dermatitis being present.

Secondly, with regard to the condition labelled "infective eczematoid dermatitis" by American authors, this, Dr. Barber thought, had been shown to be a definite entity due to epidermal sensitization to a staphylococcus, and he had confirmed Sutton's observation that in 25 per cent. of cases an urticarial eruption accompanied the eczematous dermatitis, and that positive cutaneous reactions could be obtained to staphylococcal protein.

Thirdly, the type of eczema in which Dr. Barber was at present most interested was that often termed "nummular eczema"; bilateral symmetry was characteristic of this type, the eruption occurring chiefly on the limbs. The primary lesion was often a single eczematous papule which became a vesicle of considerable size, drying up to form a single brownish scab. The nummular patches were more or less circular with sharply defined margins, and were characterized by the relatively large size of the vesicles and resulting scabs and their tendency to remain discrete. The evolution of this type of eczema made it almost certain that the toxin to which the epidermis was sensitized was borne in the blood stream either from a focus in the skin itself or from within. He mentioned three cases of this type, the source of toxin being in one a maxillary antrum, in another the teeth, and in the third apparently the gut.

Fourthly, with regard to true gouty eczema, Dr. Barber thought they were all agreed that in these days it was rare; it could be recognized clinically and distinguished from other forms of eczema. Dr. Oriel had obtained very interesting results from the investigation of the blood uric acid in various types of eczema and in seborrhoeic patients. He found that in the latter the blood uric acid was normal and the blood pressure not raised, whereas in the cases that Dr. Barber had diagnosed as gouty eczema the uric acid content of the blood was markedly increased and the blood pressure invariably high. It also appeared from Dr. Oriel's series of cases that the great majority of patients with true gouty eczema died before old age, for eczema in the aged was found to be unaccompanied by an increase in the blood uric acid or blood pressure.

Lastly, there was the type of eczema that occurred in patients who had inherited what Dr. Barber termed the ichthyosis—asthma—hay fever—prurigo—eczema—urticaria complex. They almost invariably suffered from infantile eczema, and later developed circumscribed prurigo, the sites of election of which were nearly always the antecubital fossae, the popliteal spaces, and the dorsal surfaces of the wrists. The majority were, perhaps, ichthyotics, but, apart from this, their skin was curiously sallow, thickened, and oedematous-looking, so that they could be recognized at a glance.

Dr. G. B. DOWLING (London) asked if the term "dermatitis" should be used for any of their cases rather than "eczema." He thought it would be convenient to retain the term for those cases of eczema which were due to contact with a known irritant, such as lime, sugar, and furniture polish, for the word "dermatitis" had an industrial significance which "eczema" apparently had not, so much so that when a patient was labelled "eczema" it was often difficult for that patient to obtain an award under the Workmen's Compensation Act, even when an award was justly due. Nevertheless, Dr. Whitfield had made it perfectly clear that there was no difference between such dermatitis and eczema on anatomical, histological, or indeed physiological grounds, if they accepted his view that an internal stimulus of some kind was essential to the production of all eczema. On this point, however, Dr. Dowling was in some doubt, and he was glad that Dr. Hallam and Dr. Barber had referred to cases in which it was exceedingly difficult to find any evidence of external irritation.

They were all agreed, as Dr. Whitfield had said, that a constitutional factor was present in all cases of eczema, and it was this that interested and concerned them most. The question arose whether many such factors might be considered to underlie different cases, or whether such a factor was essentially the same for all cases. All the evidence pointed to the view that multiple types of constitutional disturbance were responsible, and these might be either congenital or acquired. Other speakers had

drawn attention to the congenital factors which were said to create an eczematous diathesis. Of the acquired types of constitutional disturbance Dr. Dowling could think of no better example than that mentioned by Dr. Whitfield in relation to chronic varicose eczema. Dr. Dowling was convinced that this type of case was so common that in examining any case of eczema, even when the exciting factors would appear to be exposure to a definite irritant, he had made it his practice to search the whole surface for a chronic focus on the skin. He thought that such cases were etiologically of the same nature as the type of case to which Engman drew attention in 1902, and to which he gave the name of "infective eczematoid dermatitis." He then demonstrated the close relation of many cases of eczema to an antecedent pus infection, such as infected scabies, infected wounds, boils, abscesses, discharging sinuses, chronic discharging ears, and a host of other septic foci in direct relation to the skin. Generally the area of skin in the immediate neighbourhood of the septic focus was primarily the seat of eczematous vesicle formation. The eczematous eruption did not, however, remain confined to the original focus, but spread either by continuity or to distant foci on the skin, often selecting exposed parts, and usually not sparing the large flexures where friction and moisture might afford an external stimulus. The eruption was auto-inoculable, as Sutton and Fordyce had pointed out, but often the spread to distant foci was too sudden and too rapid to be accounted for in this way.

The rapidly produced general eruptions were of the most diverse types, being sometimes of papulo-vesicular type, as Dr. Whitfield had described in relation to varicose eczema, sometimes a patchy erythematous-squamous eruption, and Dr. Dowling had seen an urticarial eruption in combination with eczema of this origin. To the same group belonged those common and difficult cases of infective dermatitis of the scalp in children, following an antecedent pus infection from pediculosis capitis, spreading at times by continuity to the post-auricular sulci, the face and neck, and giving rise sometimes to patches of true eczema in distant parts. Apart from cases of eczema due to contact with a known irritant, and which, for convenience, Dr. Dowling preferred to call dermatitis, he believed that these cases supervening upon antecedent foci in the skin formed a majority of the cases of eczema with which they had to deal, and he agreed with Dr. Whitfield that it was all-important to attack the primary focus in treatment. In the present state of their knowledge it was impossible to say to what factor in the primary infective lesion the secondary reaction was due. Presumably some toxic substance was absorbed from the focus into the circulation, which had a directly poisonous action upon the skin, rendering it susceptible to the minutest stimuli from without; but they did not know whether the toxin was of bacterial origin or the result of tissue autolysis. He mentioned a case which supported the view that such toxins were not necessarily bacterial; it was a case of lupus vulgaris in a healthy butcher, no doubt of inoculated type. Dr. Dowling had used pyotropin for treatment, a preparation that acted by producing selective destruction of lupous tissue with marked suppuration. After three applications the butcher developed a crop of eczematous vesicles immediately around the patch of treated lupus, upon skin that had been bathed in pus for about a fortnight. Although pyotropin was discontinued, a week later there appeared an extensive patchy erythematous-squamous eruption over the trunk, limbs, face, neck, and scalp. It seemed that bacterial toxins could not have been responsible for the general eruption in this case, since the suppuration produced was of chemical origin and not due to infective organisms. Although in this case the primary focus of eczema healed quickly under local treatment, the general eruption persisted for about two months. The important point to decide was whether there existed, apart from the alimentary causes of which Dr. Whitfield had spoken, internal foci capable of sensitizing the skin with the production of eczema, in relation to which Dr. Barber's remarks on his cases of nummular eczema were particularly interesting.

Dr. Dowling agreed with Dr. Whitfield that Sabouraud was right in saying that pityriasis of the scalp had nothing to do with seborrhoea, although it must be admitted that pityriasis and seborrhoea were commonly associated; they arose from a common soil. In relation to pityriasis of the scalp or dandruff, however, a certain common type of true eczema did arise, as Dr. Barber had said, apart altogether from the whole group of eczematides, commonly called seborrhoeic dermatitis. Dr. Dowling's view of seborrhoeic eczema was that pityriasis of the scalp was a mild chronic infection due to the bottle bacillus. It was slightly irritable, and at times, from friction or some more obscure cause, it assumed an inflammatory aspect due to super-added staphylococcal infection. The picture was then the common dry seborrhoeic dermatitis, or it might be an acute weeping dermatitis of the whole scalp. In either case, apart from a tendency to spread to the post-auricular sulci, the neck and face, true eczema might develop in distant parts of the body. The speaker believed that an important group of infantile eczema belonged to this class. In his opinion these cases fell into line etiologically with the cases related to chronic varicose dermatitis, and with the cases of infectious eczematoid dermatitis of which he had spoken, the primary sensitizing focus in the skin being in this case the scalp, as in children suffering from pyogenic dermatitis due to pediculosis capitis. The important point to elucidate was what gave rise primarily to the acute inflammatory condition of the scalp, for all had dandruff, though few, fortunately, had seborrhoeic dermatitis. There must be another factor in this connexion.

Dr. SEMON (London) said that the known facts governing the etiology of eczema sadly needed revision and tabulation. In his view they were all contributory or associated rather than causal. He agreed with Dr. Whitfield that eczema was a condition rather than a disease—a condition which, in his experience, might be lighted up by such heterogeneous associations as glycosuria, hypochlorhydria, focal sepsis in teeth, tonsils, or appendicitis, old gunshot wounds, varicose ulcers, or the repeated and daily stimulus of chemicals as used in trade, if the subject were susceptible. The number of such possible stimuli was unlimited and ranged from simple trauma to a complex sensitivity to foreign proteins. In the case of each and all of them it seemed certain that an essential and hitherto undefined state of the skin itself must be presumed. An American author had suggested the term "tissue idiosyncrasy," which would suit as well as any other at the present time. Some slight hint as to the mechanism involved in the production of eczema was suggested by the fact that eczema never occurred on a naevus, no matter what its size or location—and all naevi lacked vaso-constrictor and dilator nerves. It might be, then, that for the exudation of eczema to take place there must be a local neuro-vascular abnormality at work.

Dr. HALDIN-DAVIS (London) approved the definition put forward by the opener of the discussion. He did not minimize the importance of the external factor in the causation of eczema, to which all dermatologists ascribed increasing importance, but there remained a large number of cases in which this factor was almost inappreciable. In his opinion more research was necessary on biochemical lines in order to discover the underlying biochemical basis of the constitutional factor. At one time he had had the idea that certain dermatoses might be correlated with one or other of the four well known blood groups characterized by their agglutinating relations; but the investigations he had made on these lines had yielded no definite result. The whole problem was exceedingly difficult, because, up to the present, their chemical methods were much too coarse to detect the minute differences between the tissue fluids of eczematous and non-eczematous individuals. He did, however, think that there was one line of investigation which might be worth while following up. Starting from the traditional idea that sugar was bad for eczema, and from the undoubted fact that diabetic subjects were unduly liable to that condition, he had examined a number of cases of eczema with a view to ascertaining whether or not

their blood behaved in an abnormal manner towards sugar. The abnormality might show itself in one of three ways: (1) there might be an abnormally high starving sugar content in the blood; (2) the sugar tolerance curve, after the ingestion of a measured quantity of glucose, might reach an abnormally high point; (3) the sugar tolerance curve, although the peak might not be higher than normal, might be abnormally slow in falling to the starvation level—it might show a "lag." With the help of Miss Wills, M.D., he had been able to demonstrate that in about two-thirds of the cases of eczema investigated there was some abnormality shown on these lines. On the other hand, he had found no abnormality of the kind in a number of healthy medical students who had acted as controls, nor in three cases of exfoliative dermatitis. But up to the present he was unable to predict from the clinical characteristics which case would and which would not exhibit the abnormality. The speaker also desired to suggest that the nervous system played a more important part than was usually suspected in determining the distribution of eczematous lesions. He had never been able to explain their marked tendency to a definite symmetrical arrangement. He did not think this could be explained by supposing that a toxin was distributed by the blood stream. If that were the explanation, why should there be symmetrically arranged lesions in isolated patches only, while the rest of the surface escaped? One would expect a generalized eruption on this theory. The system which was most symmetrical in the body was the nervous system, and he suggested with some diffidence that an eczematous patch of skin on one side influenced, through its afferent nerves and their synapses in the spinal cord with the afferent nerves of the other side, the symmetrically corresponding patch. He thought that possibly experimental work might be devised to test this hypothesis.

Sir NORMAN WALKER said it was thirty-four years since he first attended an Annual Meeting of the British Medical Association, and it was at Nottingham. He thought that Dr. Whitfield, in his definition of eczema, laid rather much stress on external irritants, yet the speaker believed that it was possible to arrive at a definition of eczema which would be generally accepted. The Dermatological Section had discussed eczema in Newcastle about thirty years ago. Allan Jamieson was in the chair, and Crocker, Colcott-Fox, Brooke, Malcolm Morris, Pringle, and Limont were present; Sir Norman Walker believed he was almost the only survivor. Then the younger generation was fighting for recognition of the very existence of external causation, and a great deal was heard about gouty eczema. That day, they had been told that it hardly existed. He did not imagine that those who strove so hard for external recognition really believed that internal influences could be ignored; but he thought they were right, in their generation, to stress the external side. Now that field had been won, and, while some had travelled further than others, nobody now denied that a very large number of all cases of so-called eczema were due to external causes. In some respects the pendulum seemed to have swung the other way, and there were those who, leading fresh advances, were concentrating on causes other than external. He was convinced that focal sepsis and internal causes, particularly substances taken into the stomach, were responsible for many cases which, for the purpose of the discussion, he was willing to call eczema. Dr. Dowling had suggested that the word "dermatitis" should be limited to such inflammations as were demonstrably due to external causes, and that the rest should be called eczema. Through his teaching career the speaker had endeavoured to direct the attention of students to the causes of disease rather than to the names attached to them, and so he believed that dermatitis, which was an admission of ignorance, was the better term until it was possible to put an adjective at the end of it. Dr. Dyson had referred to small, stimulant doses of x rays; Sir Norman Walker reiterated his warnings against the haphazard use of this powerful and dangerous weapon. He had seen so much serious damage, so many fatal cases, that it was only when he could convince himself that no other treatment would do as much good as x rays in a

particular case, that he administered them. It might be that the evil effects did not appear until years after exposure. He agreed with Dr. Haldin-Davis that they must make more use of biochemical and other laboratory methods. Advancing science was bringing to their aid other means of investigation, and the training of the dermatologists of the rising generation must be longer and broader than that of their predecessors. He was himself making use of the cutaneous tests.

The PRESIDENT felt that it was first of all essential to come to an agreement as to the characteristic clinical features of the eruption for which the title of "eczema" should be retained. While they discussed the etiology of eczema they ought first to be sure that they were referring to the same complaint. One observer might maintain that a dermatitis which he called eczema was the result of internal causes, another that eczema was of external origin; but if they used the word "dermatitis," or even the word "eczema," in a vague sort of way it might well be that the two observers were dealing with different eruptions, and that both were right. If they employed the term "eczema" as a sort of refuge for those forms of dermatitis which did not belong to a definite category such as that of impetigo, of psoriasis, of urticaria, or other eruption with clearly recognized characters, they were possibly dealing with several eruptions of different nature and origin. Even if they said that to be an eczema an eruption must be a dermatitis with redness and vesication or weeping and itching, they were still too vague. It was not many years since a common eruption with all these characters was confidently regarded as an eczema of gouty origin, but now, as was first shown by Dr. Whitfield, it was known to be of external microbial origin, and was labelled eczematoid ringworm of the extremities. He was quite in agreement with Dr. Whitfield that unless they restricted the meaning of the term "eczema" to one decided type of inflammatory reaction they were not likely to come to any clear conclusion as to its etiology.

Dr. Whitfield had taken as his base the essential lesion of eczema as defined by Willan—namely, the crowded, pin-head sized, deeply formed vesicle—and he had very rightly emphasized the fact that this was a vesicle formed, not on the surface of the skin, but in the deeper parts of the epidermis—that it was, indeed, what they now called an intradermic vesicle. The President would add to this statement that these crowded pin-head sized intradermic vesicles were set upon a red and oedematous base. It might be that in the very earliest phase the minute vesicles were not accompanied by any obvious inflammation at their base, but this phase soon passed, and in the matured patch of eczema they saw a roughly circumscribed area of red swollen skin studded with minute vesicles or with weeping points. This swelling of the epidermis was particularly obvious when they pinched up the patch between the fingers, for it was then found to be twice or three times the thickness of the normal skin around. In Bateman's *Delineations of Cutaneous Diseases according to Willan* (1817) there was a coloured drawing, Plate LV, Fig. 2, "Eczema Impetiginoides," in which this condition was exactly described. The President regarded, then, the essential lesion of eczema as a roughly circumscribed patch, red and swollen, and studded with minute vesicles or weeping points, and accompanied by itching and burning. For many years past he had been accustomed to refuse the name "eczema" to any lesion which did not present these characters. The eruptions called dermatitis traumatica or dermatitis venenata, which were frankly the result of contact with certain local irritants, such as primula and hair-dye, did not present these characters. Such a dermatitis presented an area of very closely set, quite superficially formed larger vesicles, which might even run together into bullae; or there might be an erythema without deep oedema, and with a tendency to superficial vesication or blistering. The lesion he considered to be the essential lesion of eczema was seen in its most characteristic form in the facial eczema of infants and in patchy eczema of the arms and legs and hands of adults.

He had never been able to satisfy himself that there was any inherited or acquired susceptibility of a gastro-

intestinal toxæmic nature which rendered eczematous patients more sensitive to external irritants. He was inclined to believe that eczema was a normal reaction in normal persons to small repeated external irritations. A combination of local circumstances had, he thought, more to do with the first onset of an eczema than any predisposing supersensitiveness due to internal causes. A small irritant, and particularly some form of chemical irritant, combined with heat from warm clothing, or from warm weather or sun exposure, with friction from the clothes or from scratching, led to the first patch of eczema, with subsequent spread to other parts from irritation of the discharges, or possibly from absorption of toxins from the original patch.

A true eczema might arise also as a sequel to a more violent dermatitis, such as dermatitis traumatica. If the special irritant which had given rise to the dermatitis traumatica was removed the dermatitis speedily disappeared, and did not become an eczema. But if the contact with the irritant was continued the type of reaction might alter and the dermatitis be converted into a true eczema. Thus they might sometimes find a true eczema taking its origin from what was primarily a dermatitis due to some special irritant, such as a hair-dye or a dyed fur collar; or an occupation dermatitis might be converted by repeated irritation into an occupation eczema. In all cases of eczema he believed that if they diligently traced back the history of the eruption they would generally find that the earliest onset was associated with some such combination of local irritation with other conditions such as he had mentioned. Dr. Whitfield's apt quotation from Bateman, with which he had concluded his address, was very appropriate to the subject of eczema, and if at this meeting they had done nothing more than define exactly what was meant by eczema, he thought that they had accomplished very much.

Dr. WHITFIELD replied, dealing with the points raised by various speakers.

## DISCUSSION ON TREATMENT OF PSORIASIS.

### OPENING PAPERS.

I.—ROBERT W. MacKENNA, M.A., M.D.,

Honorary Dermatologist, Liverpool Royal Infirmary; Lecturer in Dermatology at Liverpool Infirmary.

THOUGH psoriasis is one of the oldest and commonest diseases of the skin, we do not yet know how to eradicate it. We may know how to treat it, and in most cases we may venture to promise a sufferer that his eruption can be made to disappear; but we cannot, with any degree of confidence, assure him that his first attack will be his last. Indeed, if we do not allow a groundless optimism to nullify experience we are bound to warn him that, in all likelihood, he will be the victim of recurring attacks for the rest of his days.

We are in the dark as to the cause of the disease; therein lies our chief difficulty, for we are aiming at a target which we cannot see, and until the etiology of psoriasis has been established beyond cavil much of our treatment must be empirical.

I take it that my duty in opening this discussion is not so much to indicate some stereotyped method for the treatment of the disease as to touch upon some points that may stimulate controversy. I do not, therefore, propose to waste your time by passing under review the numerous remedies that may be employed to cleanse the skin of the eruption. I intend to speak only of those agents or methods of treatment of which I have made careful trial, and I shall give a brief account of some clinical experiments in therapeutics entered upon in the hope that they might yield fruitful results. This will, I imagine, afford ample ground for discussion; and as subsequent speakers will probably contribute something from their own experience we shall, I trust, have a profitable exchange of ideas and learn in what measure the prognosis in psoriasis has been altered by the application to its treatment of some of those

modern methods that have yielded good results in the treatment of other dermatological conditions.

May I begin with a simple statement about which there can be no diversity of opinion? Our treatment must be modified according to the stage of the disease and the character of the eruption.

Probably we have all seen the disastrous results that may follow the injudicious use of a powerful remedy like chrysarobin in a case of acute psoriasis. In its stage of evolution psoriasis must be treated with soothing remedies. If the eruption is coming out with great rapidity, in small punctate lesions, associated with subjective symptoms of heat, itching, and a sense of tenseness of the skin, the patient should be put to bed, the bowels should be kept freely opened, the diet should be light and non-irritating. In such a case all that is required for local treatment is an oily calamine lotion to which a small proportion of ichthyol may be added. This will afford great relief, and if at the same time antimonial wine, a remedy that is all too often forgotten, is administered in doses of 7 to 10 minims three times a day, the acute stage soon passes into the quiescent stage, when more active remedies may be safely employed.

Negative results have their value, more particularly when they do not accord with the more optimistic results of others. So I shall begin by mentioning some failures.

**Emetine Injections.**—Shortly after the termination of the war I heard that emetine had been used with some success in the treatment of psoriasis among our soldiers in the Near East. I made a trial of it at once, administering it hypodermically in doses of 1/8 grain of emetine hydrochloride, progressively increased to 1 grain daily, given in two doses of half a grain each. During the treatment the use of all other remedies was discontinued. In all, each patient received from 7 to 10 grains of the salt. Eight patients were treated; all were in the quiescent stage. The results were disappointing. I was not able to satisfy myself that a single one of them derived the slightest benefit from the treatment.

**Arsenic and Salvarsan.**—Arsenic has long been reputed to have beneficial effects in psoriasis. But I believe our forefathers greatly overrated its efficacy. It is unsuitable in the acute or subacute stage. It is, I think, most useful in the first attack of the disease, when the process of involution or retrogression has already commenced, and then it has to be pushed to the limits of tolerance before its effects become appreciable. But it was natural that on the introduction of salvarsan and neosalvarsan, which presented us with the opportunity of administering an arsenical salt in massive doses, one should seek to test their efficacy in the treatment of psoriasis. My experience with these arsenical preparations has been disappointing. Salvarsan, whether administered intramuscularly or intravenously, does not have any marked or predictable effect on a psoriasis eruption. At the best the effect is uncertain. I have never seen its administration cause the eruption to disappear. Any improvement has been transient, and I am convinced that in two cases salvarsan, administered intravenously, made the eruption more rebellious to the local treatment which was subsequently applied. These are negative results which, possibly, may not fit in with your experience.

We know how psoriasis reacts to the impact upon it of some systemic infection, such as scarlatina or measles. We are aware that its lesions almost always disappear during pregnancy, to reappear during lactation. We know how a change of climate or locality may influence it and how its outbreaks are characterized by a seasonal periodicity. All these facts would seem to point to the conclusion that psoriasis can be influenced beneficially by various disturbances in systemic equilibrium. It is natural, therefore, that we should seek some solution of the problem by endeavouring so to disturb artificially this systemic equilibrium as to cause the eruption to disappear. The "shock" of "foreign protein" injections would, *a priori*, seem to afford us a possible means of achieving this end. Of recent years the literature has contained sundry reports of results following the use of peptone injections—milk injections, homologous and heterogenous serum injections, etc. These results have varied greatly and a judicial review of them leaves a vague sense of uncertainty in the mind.

With the help of my clinical assistant Dr. Elizabeth Hunt, a series of observations has been carried out in my out-patient department, and I should like to take this opportunity of acknowledging my great indebtedness to Dr. Hunt for her invaluable co-operation. Unfortunately, as all our patients were out-patients, we were compelled to limit our investigations to the effect of remedies not likely to produce a profound degree of shock. But there were other agents available.

In the reports of other investigators one finds that all too often vigorous local treatment of recognized efficacy has been carried out simultaneously with injection treatment of all kinds. This introduces a disturbing factor and makes it extremely difficult to assess accurately the value of the "foreign protein" or other injections. To eliminate as far as possible this source of fallacy we were careful to confine local medication to a mere dermatological placebo—a weak boracic ointment—until at least five or six injections had been administered.

**Auto-haemotherapy.**—Ten patients were treated by auto-haemotherapy. This is a method of treatment of recognized value in some of the pruriginous dermatoses, but it would seem to be of no use in psoriasis. The patients received from four to eight injections, at intervals of four days or a week, of 5 c.cm. of their own blood drawn from a vein and injected straightway into the buttock. In no case was there any appreciable improvement. This method does not seem able either to shorten the period of evolution, to influence beneficially the quiescent stage, or to hasten the process of involution or retrogression. Nor does it seem, as has been suggested by some observers, so to act upon the patients as to render them particularly amenable to whatever local treatment might subsequently be applied.

#### *Injection of Vaccines.*

It is beginning to be recognized in "foreign protein therapy," vaccine therapy, and all treatments of the kind, that it is the manner in which the tissues of the patient react, rather than the particular substance injected, which gives the result. There is no recognized relationship between *Bacillus typhosus* and psoriasis. But Engman and McGarry,<sup>1</sup> injecting intravenously doses of vaccine containing 100 to 500 million of typhoid bacilli, brought about a rapid disappearance of the lesions of psoriasis. But relapses were speedy. The results must be attributed to the response of the bodily economy to the violent shake-up produced by the vaccine, rather than to any direct and specific action of the organismal content of the injections on the lesions of the disease.

Similar observations have been made by Scully and Cadbury, while Sutton<sup>2</sup> claims good results from the use of an autogenous colon bacillus vaccine. But Sutton combined with his vaccine therapy active treatment with chrysarobin.

I have not tried typhoid vaccine for psoriasis, but I have used a mixed polyvalent staphylococcal vaccine, in doses of 50 to 100 million hypodermically, in several cases without any appreciable result. In addition Dr. Hunt and I have made a careful trial of a polyvalent mixed vaccine, prepared by Danysz's method from the intestinal flora. We have treated patients with such a vaccine made from their own bowel cultures, and, in addition, we have used a mixed stock entero-vaccine which contained in each cubic centimetre 20 million colon bacilli, 20 million enterococci, besides staphylococci and diplococci of different kinds.

Sixteen cases were treated with this entero-vaccine. Beginning with small doses of 0.2 c.cm., the injections were repeated at intervals of four days or a week in increasing dosage until 1 c.cm. was reached. No single dose was larger than 1 c.cm. In all, the patients received from three to ten injections. Local reactions were slight. Systemic reactions occurred occasionally, usually taking the form of diarrhoea. Occasionally there was a subjective focal reaction, the lesions itching intensely. This subjective symptom we may, I think, interpret as the evidence of a focal reaction not gross enough to produce visible changes in the lesions. In three of the patients there was a

marked indicanuria at the beginning of the treatment, and it is noteworthy, as Dr. Hunt pointed out, that those patients who had indicanuria derived most benefit from the injections.

Reviewing the records of the sixteen cases, we find that in four cases there was a noticeable improvement. In six cases there was no definite improvement. In five cases the patients attended so irregularly that the treatment did not have a chance; and in one case, after ten injections, there was a slight, but definite change for the better. In no case did entero-vaccines alone produce a complete disappearance of the lesions. Their place would, therefore, seem to be, if they are to be conceded a place at all, that of an aid to other treatment, rather than a complete treatment in themselves.

Man in his puny way tinkers at things. When Nature takes a hand in effecting a cure she can act dramatically and with vigour.

In 1922 a nurse, aged 23, who had suffered from intermittent outbreaks of psoriasis from the age of 11, but who had been free for nine months, consulted me about an eruption which had broken out on her wrists and the flexor aspects of her forearms. The lesions were tiny, red, pin-head papules which itched intensely, and which looked like the papules of lichen planus. There were on the first occasion when I saw her no lesions on the "sites of election" of psoriasis. Almost with the rapidity of one of the infectious exanthemata the eruption broke out on the trunk and limbs, the lesions closely resembling in shape and character those on the wrists and forearms. There was a slight rise of temperature during the onset, but it did not exceed 99.5° F. Soon the older lesions on grattage yielded the characteristic signs of psoriasis and over the prepatellar regions and at the back of the elbows there was a characteristic grouping of lesions which quickly became confluent. The patient felt out of sorts, and the intense itching disturbed her sleep. She was put to bed, freely purged, kept on a milk diet, and given 5 minim doses of antimonial wine thrice daily, with calamine lotion as a local application. A week after the appearance of the lesions she complained of a dull ache in the left armpit. On examination there was a deep-seated tenderness and some infiltration. She was developing an axillary abscess. As the abscess grew the eruption on her skin began to pale, the intense itching diminished, fresh lesions ceased to appear, and except for the pain of the ripening abscess the patient's condition was much more comfortable. Recognizing in this concomitant septic infection a useful ally, I was in no hurry to open the abscess prematurely. I waited until it had penetrated almost to the surface, and on the twelfth day from the date when she had first complained of pain in the axilla I opened it by Hilton's method. By this date—that is, nineteen days from its first appearance—the eruption had almost completely disappeared, and on the twenty-third day after the first outbreak—that is, four days after the opening of the abscess—the last skin lesion had disappeared. It had been a fulminating outbreak, controlled, subdued, and conquered by a coincident septic process. The patient did not have an outbreak again for close on fifteen months.

With this case I have always associated the boast of an old general practitioner who twenty-five years ago told me that he could cause an outbreak of psoriasis to disappear by rubbing undiluted tar ointment into the hairy parts of the legs or thighs until he set up a violent folliculitis. The cure seems almost worse than the disease, but that shrewd old practitioner had made an observation that is quite in the line of some of our modern practice.

#### *Treatment by "Fixation Abscesses."*

In a mild way I have tried to imitate Nature; but a "fixation abscess," such as was commonly produced by our forefathers in the treatment of pneumonia, puerperal fever, and deep-seated inflammations, is a poor substitute for a violent infection such as the nurse developed. For the purpose of producing "fixation abscesses" I have made use of the preparation known as terpichin. It contains a very pure turpentine, free from rosins and oxides, and in addition a small proportion of quinine, which is said to increase its efficacy, and a local anaesthetic. The dose is 1 c.cm., administered weekly or twice a week. The injections are practically painless. Introduced into the gluteal muscles, terpichin is said to produce small necrotic areas—sterile abscesses.

Fourteen patients were treated with these injections. Seven showed distinct improvement within a few days of their first injection. One of these patients was a woman who previously had had a course of six injections of her own blood, and also a course of injections of intramine, without much, if any, apparent benefit. The improvement noticed in these seven cases after the first injection was

maintained and increased by each subsequent injection. Two patients showed slight improvement after two injections. Two patients ceased attending after the first injection, and one after the second injection. Two showed no improvement after four injections. In no case did terpichin unaided bring about the disappearance of the eruption, but in a majority of cases—in nine out of fourteen—it exerted a beneficial effect. Its use certainly helps any local treatment that may be employed. It can quieten down the period of evolution, shorten the quiescent period, and promote the rapidity with which the lesions disappear.

For many years I have been persuaded by clinical observation that the administration of sulphur in some assimilable form exercises a curative effect upon psoriasis in all its stages. For the past eight or nine years I have given colloidal sulphur in doses of 1 to 2 drachms thrice daily to patients suffering from psoriasis, and in many cases it has been of indubitable value. But its use has always been combined with some local application of known efficiency.

**Injections of Intramine.**—In my search for a sulphur derivative that could be administered intramuscularly, my choice fell upon di-ortho-amino-thio-benzene, better known, perhaps, as intramine. I had had experience of its usefulness in cases of seborrhoeic dermatitis, so I decided to try it for psoriasis. Fifteen cases have been treated with intramine. The dosage given was 0.75 c.cm. to 1.5 c.cm. once weekly. Two of the patients gave a positive Wassermann reaction; they showed a definite and rapid improvement. Six others began to improve slowly—that is, after the third or fourth injection—and in six no appreciable change was visible, while one woman stated categorically that the injections made her worse. In no case did intramine alone cause a complete disappearance of the lesions. In every case in which it was administered during the evolution of the eruption it hastened the onset of the quiescent stage, and when local treatment was superadded the lesions cleared up fairly rapidly, even in cases where the administration of the injections had produced little, if any, visible effect.

**X Rays and Ultra-Violet Light.**—Brief mention may be made of x-ray and photo-therapy. In the x rays we have a powerful remedy that may be relied upon to cause the disappearance of any patch of psoriasis subjected to their influence. The drawback is that general irradiation with x rays is impracticable; and, further, the treatment is not one that can be repeated with impunity whenever an attack occurs. But in the x rays we have a means whereby we can quickly, safely, and cleanly cause the disappearance of psoriasis lesions from such limited exposed areas as the face, the neck, and the hands. Three-quarters of a pastille dose, repeated if need be at the end of a fortnight, will usually suffice to cause any but the most obstinate psoriatic lesion to disappear. The reaction is, however, an entirely local one, and affects only the lesions irradiated. There is no reaction either in remote lesions or in adjacent lesions which have been protected from the rays. But a caution must be entered. When the skin is actively throwing out psoriasis lesions—when a mere scratch mark upon it will be followed by a trail of psoriasis papules, the unaffected skin is in an extremely sensitive state, and may react violently to radiations which at other times would produce no disturbance. Therefore, the normal skin between the lesions should be guarded; and, if possible, x-ray treatment should not be given during the acute stage.

Generalized irradiation with the x rays is impracticable; but general irradiation with the ultra-violet rays is not only a practical but extremely efficient, rapid, and cleanly method of treating the disease. My experience is that it is useful in all stages of the disease, though in the acute stage it is best to proceed cautiously until one sees how the disease reacts. I have used an air-cooled mercury vapour lamp, and so far I have not encountered a case in which there has not been a prompt and gratifying response to the treatment. One patient in particular deserves mention.

A woman, aged 52, had been a sufferer for twenty-seven years from the most rebellious form of psoriasis I have ever had the misfortune to meet. The only remedy that seemed to have the

least effect on her eruption was chrysarobin—but she had been so disappointed with the fact that though chrysarobin caused her eruption to disappear it had no effect in delaying its return that she refused to use it. Six generalized erythema doses of ultra-violet light at intervals of a week or ten days caused her eruption to melt down from thickened scaly plaques to little more than pigmented areas with scaly borders, and from my experience in other cases I am hopeful that there will be a complete disappearance of her eruption.

According to Jesonek ultra-violet rays exert their greatest influence upon the basal cell layer of the epidermis, and as it is in the basal cell layer that the keratoplastic changes begin we have in the ultra-violet rays a means of reaching with a fair degree of accuracy the layer in which the pathological changes take origin.

Having touched on several matters that may promote discussion I should like in conclusion to say a word or two on the more orthodox lines of treating psoriasis.

#### Other Methods of Treatment.

First, as to diet. I have kept patients on a pure rice diet till they rebelled vigorously—and their psoriasis remained unchanged. There is, in my experience, no special merit in a purely fruit and vegetable diet in psoriasis; and a purely meat diet, though it is said to have worked wonders in the classic case of Dr. Passavant of Frankfurt, has failed in other cases. I believe that what comes out of the bowel is more important than what goes into the mouth. Schwartz<sup>3</sup> found that 20 per cent. of patients with psoriasis gave evidence of protein putrefaction in the bowel, and 26.6 per cent. of carbohydrate fermentation. Therefore, keep the bowels freely opened, and, if need be, use high irrigation. A golden rule is to cut down excess both of carbohydrates and of proteins, for in this age everyone tends to eat too much. An ordinary mixed diet, suited to the digestive capacity of the individual patient, is all that is necessary. Tobacco should be cut down, and alcohol absolutely forbidden.

As to general hygiene, the patient should lead a quiet life, free from excesses of exertion, bodily or mental, and frequent baths, either with ordinary soap and water or medicated with sulphur or tar, may be taken.

As for internal medication, I have already mentioned arsenic, sulphur, and antimonial wine; potassium iodide is sometimes useful, and salicin is of undoubted value; it is specially useful in the acute and subacute stages of the disease, and also in the rapidly spreading varieties, as well as in cases associated with arthritis. It should be given in doses of 10 to 15 grains thrice daily, preferably in solution. Most of us, from experience, will, I think, be able to endorse Pernet's<sup>4</sup> opinion as to its value.

Glandular extracts I have found uncertain and disappointing.

Of local applications I need not say much. Doubtless each of you has his favourite ointment or mixture of ointments. I need do no more than mention chrysarobin. Its remarkable powers of clearing up an eruption are indisputable; the method of its use has been stereotyped by custom and experience, and any textbook will supply the details. But it has disadvantages and limitations, and in my opinion an attack of psoriasis cleared up by its use tends rapidly to recur.

Tar in one of its many forms comes next in efficacy to chrysarobin. I think the use of tar delays the return of the eruption for a longer period than the use of chrysarobin. Sulphur, salicylic acid, mercury, each has its place in the external treatment, and pyrogallol acid is specially useful for small obstinate patches.

Time will not permit of my devoting any attention to the regional treatment of the disease, and discussing special remedies for such regions as the scalp or the nails.

A cardinal principle that ought never to be forgotten is to begin with weak concentrations of remedies, and increase their strength as need arises.

I have found the following ointment extremely serviceable—namely, equal parts of tar ointment, salicylic acid ointment, dilute mercury nitrate ointment, and ointment of the glycerole of lead. The proportion of tar ointment may be lessened or increased according to the stage of the disease. There is a rational basis for this polypharmacy for tar and mercury are powerful reducing agents, salicylic acid is keratolytic, and glycerole of lead is hygroscopic.

and soothes inflammation. The ointment is tenacious and adhesive, and requires fairly heavy massage to rub it in. This in itself is an advantage, because massage promotes the lymph flow in the skin and consequently tends to drain the papillae which in psoriasis are always somewhat oedematous. But we must not forget this—our treatment of psoriasis to a very large extent consists simply in removing the visible lesions. The dyskeratosis, which exhibits itself to the naked eye in the reddened plaques covered with micaceous scales, is a mere external expression of some deep-seated pathological change. Of the true nature of this deeper-seated process we know nothing. The microscope reveals histological changes—it leaves us groping for the cause behind them; and we shall continue to grope until the physiologists and the biochemists can tell us a little more about the intimate processes of cell metabolism, and the response of the individual cell in the skin to stimuli from without or within.

As yet we have no remedy that can cure psoriasis; nor, with the exception of chrysarobin and possibly tar, any agents that can cause the eruption to disappear with precision and promptitude. Nor can we prevent the recurrence of the eruption. Indeed, we may say of psoriasis what Horace long ago said of Nature:

*Naturam expellas furca, tamen usque recurret.*

#### II.—E. F. SKINNER, M.B., F.R.C.P.,

Physician in Charge of the Skin Department, Royal Hospital, Sheffield.

PSORIASIS is one of the oldest known diseases of the skin, and yet in spite of innumerable observations its secret still eludes us. It is, moreover, one of the most striking of the dermatoses, and its frequency and saliency render its mystery all the more remarkable.

In a discussion last year I stated that, in my opinion, many of the dermatoses were pattern-reactions of one kind or another, due to some underlying metabolic change, and that certain skins reacted to changes in cell metabolism with a production of a definite pattern rash—that is to say, an individual whose skin tissues are in any way interfered with biochemically will always tend to show reaction in the skin according to a certain pattern. Psoriasis, I think, pre-eminently illustrates this, since attacks of the disease may be precipitated by the most varying of causes. For instance, I have seen in one patient a severe attack of psoriasis follow a definite trauma to the skin of the leg, an attack which lasted some six months; it cleared up completely, only to be followed about twelve months later by a second attack, which was precipitated by severe mental shock—the patient, a lady, awoke to find herself in bed surrounded by flames, the bedroom having caught fire. It appears to me that the secret of psoriasis lies in some intimate biochemical change in the cells of the growing skin, and until many more chapters have been written on the subject of the cell colloids our understanding of various rashes which constitute the dermatoses must remain incomplete. Any treatment, therefore, of one of these rashes must be entirely empirical and dependent on past experience, and in approaching the discussion of psoriasis it may be useful to take one or two well recognized therapeutic measures and compare them in detail rather than to refer to several methods, many of which are of recent origin.

Chrysarobin and x rays have now taken their place as reliable allies, and the method of comparison has been as follows. I chose a certain number of cases of psoriasis as nearly as possible in the same state and of the same type, submitting one group to the routine chrysarobin treatment and the other group to x rays. The dose of this was one-third of a pastille dose over any single area; many areas were treated at one sitting, the intervals between them being seven days. Both groups were kept

under the same conditions of environment, rest, diet, etc., and no internal remedies of any kind were employed. Photographs were taken before, during, and after the completion of the course of treatment, and biopsies were made in all cases from the same area of the body (front of the thigh) to ensure a comparable skin architecture.

In my opinion chrysarobin gives the most satisfactory results; its effects are more quickly produced and last much longer, and I am quite sure that anyone who cares to master the few rules of chrysarobin treatment can confidently attack any case of psoriasis with a fair hope of success.

[Dr. Skinner here showed a number of slides illustrating the results of his treatment.]

I think it will be found that a very widespread chronic eruption of psoriasis can be removed entirely within the space of three or four weeks by the careful use of chrysarobin; and further, that a similar result is obtainable with x rays, though it requires a much longer time. The interval of freedom in the latter cases would seem to be much shorter.

I would now like to present to you my conception of the manner in which these two therapeutic agents exert their influence, deduced from the histological appearances of the skin during the various stages of the treatment. Deductions from histological appearances are open to the objection that such changes are poor indications of the nature of intimate biochemical processes; but the ruins of a house will give some indication as to the nature of the destructive agent and in what direction its forces have been exerted, and similar deductions can, I think, be made from a study of sections of skin.

I am of opinion that the vital change in psoriasis is one which occurs in the epidermis, and is represented by a rapid and irregular growth of the prickle-cell layer showing itself by an invasion of the derma. It is difficult to look at the irregular finger-like processes of the Malpighian layer without being driven to the conclusion that these cells are actively invading the derma. This may be the result of a varying resistance in the subpapillary layer of the skin, the interdigital areas representing peaks of greater resistance. It may be suggested that this hypothetical resistance results from the varying vascular conditions obtaining in the papillary layer, and may be due to differences in oxygen tension in different parts of the vascular bed in this situation. But whatever the explanation there can be little doubt of the altered vascularity, since the dilatation of the venous channels in the papillae is easily seen. This engorgement causes exudation of serum and a few leucocytes, giving rise to the spongiosis of the epidermis and the so-called "miliary abscesses" in the upper layers of this structure.

The histological changes are very definite, and it seems to me that they must bear some relation to the marked change taking place in the clinical condition. Although I have examined only a few cases for the purpose of this discussion from this point of view, I cannot help thinking that a possible explanation of the action of chrysarobin other than the usual unsatisfactory one of a germicide may be adduced. It has been shown many years ago by Stricker, and more lately by McDowell and Hemmingway, that the abstraction of oxygen brings about constriction of capillaries. Chrysarobin is admittedly a very powerful reducing agent, so that it appears reasonable to consider the action of chrysarobin as one of abstraction of oxygen from the capillary loops, whether it is easily conveyed by inunction, bringing about an immediate constriction in the previously dilated channels. Such constriction will have as a result an increase in the vascular resistance throughout the rest of the derma, with a consequent resultant inflammatory exudate both of cells and serum. This will in consequence raise the intradermal tissue pressure and the invasion of the epidermal line will be straightened out. Not only is this line straightened out but the pressure is increased beyond the normal and the epidermis is actually driven back. I would venture to suggest, then, that the essential change in psoriasis is brought about by a lessening in the intradermal pressure and seems to be associated with an altered oxygen tension in the capillary venules.

What brings about the ill balance between the epiderm and the derm is the secret of psoriasis, and will doubtless be found eventually in cell electrophysics; but the action of chrysarobin is definite and points to a readjustment of this balance. The action of  $x$  rays is apparently very similar, at any rate so far as the histological appearances go, but I do not know sufficient about the chemical effect of such rays to suggest that they also act by an abstraction of oxygen from the tissues.

With regard to other methods of treatment I can only record a very brief experience. Arsenic in my hands, given to the limit of tolerance by the mouth, or by intravenous administration of arsenobenzol compounds, has proved disappointing, nor have I ever seen any results from administration of thyroid extract, except in one young woman whose psoriasis was connected with pregnancy and in whom exhibition of the gland extract certainly appeared to have a very decided influence.

In spite of Dr. MacKenna's statement to the contrary, I have found no benefit from ultra-violet light therapy, though I admit that my experience in this has been very slight, and I should be delighted to hear the opener's views corroborated, as any method of light therapy which can be applied over a large area has obvious advantages over  $x$  rays.

I would summarize my conclusions as follows:

1. Psoriasis may be treated with some prospect of success both by chrysarobin and  $x$  rays, the effects being produced more quickly and lasting longer by the former method.

2. Both remedies appear to produce the same histological picture—namely, a remarkable flattening of the papillary body and a probable increase in the intradermal pressure, which suggests that the cause of psoriasis may be a process which lowers the general dermal resistance.

#### GENERAL DISCUSSION.

Dr. W. DYSON (Manchester) said that, in his opinion, the first and most important line of treatment was rest. In his experience diet had little or no influence on the disease, but he always insisted on the absolute prohibition of alcohol in every form. As regards drugs, he found that salicin was most useful in the acute irritable stage, and arsenic when the inflammation had subsided and in the more chronic types of the disease. He had not seen any benefit from thyroid extract unless given in doses sufficiently large to make the patient ill. Locally, in addition to chrysarobin and tar, which Dr. MacKenna had mentioned as the most useful applications, he should like to add pyrogallol acid. Tar had the disadvantage that its long-continued use was apt to cause a pustular folliculitis and obstinate furunculosis. He had had no experience of haemotherapy as a treatment for psoriasis;  $x$  rays he no longer used, although he had done so in the past, as he found it gave no better results than other remedies and it entailed some risk to the patient. He had used injections of various bacteria—*B. coli communis*, typhoid bacilli, and staphylococci; they certainly had some influence on the disease, but he had never been able to clear a case by this method without the aid of local treatment. He did not think that it made any difference to the results obtained whatever species of micro-organism was employed. Lately he had been in the habit of using, after he had cleared a case by the usual methods, and for the purpose of preventing recurrences, a polyvalent staphylococcal vaccine (1 c.cm. = 1,000 million staphylococci) detoxicated by being heated for half an hour at 70° C. He gave a dose of 1 c.cm. and repeated it every three months, being of opinion that it diminished the chances of recurrence. In some cases this method failed, possibly owing to wrong dosage, or wrong length of interval between the doses in the individual case.

SIR NORMAN WALKER found himself in agreement with the opinion that a great many of the recently vaunted remedies had not stood the test of experience. He thought that Dr. MacKenna was too pessimistic about the old Fowler's solution. For years the speaker had taught that arsenic was certain to do harm in acute cases, and he had advised his students never to use it, such, but a pub-

lished opinion of Dr. Whitfield's to the contrary made him reconsider the matter. The results of his experiments were that quite a number of patients to whom previously he would not have ventured to give arsenic were greatly benefited. Sir Norman Walker was interested in Dr. Whitfield's reference to  $x$  rays and ultra-violet light. Many years ago Novins Hyde had argued that psoriasis was one of the prices of civilization, and that it was hardly known among negroes living in uncivilized conditions in Central Africa. Hyde had constructed in Chicago glass house (dim glass houses) on the top of a sky-scraper building where patients were exposed to such rays of light as penetrated the glass. He claimed that the effects were quite remarkable, and, when it was first noticed that  $x$  rays could cause patches of psoriasis to disappear, the possibility occurred that some rays were common to  $x$  ray and sunlight and that to these the benefit might be due. In the days when ladies' blouses were known as "peek-a-boo" the speaker had observed that the very large V which they often exposed was an area which was generally free from psoriasis. Dr. MacKenna seemed almost to prefer tar to chrysarobin. Sir Norman Walker agreed with him that the effects of tar lasted longer than those of chrysarobin unless the latter was very efficiently used. But they should not forget that the skin showed idiosyncrasies to remedies as well as to accidental irritants, and that a person whose skin was irritated by pine tar might be benefited by birch or coal tar. Like Dr. MacKenna, he had not found that diet, however unpalatable it might be made, could be depended on to give much help, but he agreed with him still more cordially in the remark that alcohol always did harm. Patients who had psoriasis should be total abstainers. Dr. Skinner's demonstration had been most interesting, and, to one who had long pinned his faith to chrysarobin as the most efficient treatment, it was very gratifying to find so valuable a recruit demonstrating its effects so strikingly. The first outbreak of psoriasis should always be treated seriously, and the same care and attention should be given as in the case of an acute illness; the child should be put to bed and treated until the eruption had disappeared. If that were always done, there would be far fewer cases of recurrence, and there would also be fewer if patients did not somehow get the idea that psoriasis was bound to recur.

Dr. MacKENNA replied very shortly, and the proceedings of the Section terminated with a hearty vote of thanks to the President.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### RECOVERY AFTER MASSAGE OF THE HEART.

I READ Mr. Girling Ball's article, in your issue of April 24th (p. 732), with much interest. About eighteen months ago I had a somewhat similar experience, which I only refer to now as it may have some bearing on Dr. Harrington Sainsbury's letter (May 22nd, p. 883) relative to Mr. Girling Ball's case.

A man, aged 40, was admitted to the Royal Infirmary, Dumfries, on November 27th, 1924, with a history of persistent vomiting. There was nothing in the history or the clinical examination which pointed to a definite diagnosis, and  $x$ -ray examination was negative. Nothing abnormal was found in heart, lungs, or secretions. I performed exploratory laparotomy on November 30th. My house-surgeon, Mr. M. G. Wright, gave chloroform, and the patient took the drug well. I thought the stomach was normal in appearance and size, but detected something abnormal, round and hard, behind it. On lifting the omentum, transverse colon, and stomach forward, I found a hard gland, with rough uneven surface, about the size of a Tangerine orange—in the tissues the product of an old tubercle mesenterica—lying fixed in an angle. At the root of the mesentery, in the duodeno-jejunal angle. At this point, without the slightest warning, the patient's heart and respiration absolutely stopped. His colour was ashen grey, the conjunctivae were dry, the pupils dilated and fixed. The usual restorative measures were adopted—head lowered, tongue brought forward, artificial respiration, warm fomentations, chest wall over the heart, etc.

It was soon apparent that these measures were hopeless, and I had thus wasted several minutes before I enlarged the wound in the abdominal wall and massaged the heart through the

AUG. 21, 1926]

# MEMORANDA.

THE BRITISH  
MEDICAL JOURNAL 343

diaphragm. The heart was still and flaccid, but after a considerable interval (about two minutes) it began to beat—very feebly at first, but gradually increasing in strength. The respiration started again soon after the heart. Warm applications were maintained on the chest wall, and I dissected away the gland. This took some time, fully half an hour, as the tumour was very adherent to surrounding structures, mesenteric vessels, etc. The patient remained quite well till the end of the operation and I had no further anxiety about him. He was discharged from hospital three weeks afterwards quite well and has remained so.

I now come to the point in Dr. Sainsbury's letter. Mr. Girling Ball injected adrenaline into the heart muscle, and Dr. Sainsbury inquires whether that was not the chief agent in the recovery of the patient, and not the heart massage.

I injected no drug into the heart muscle, or elsewhere. No doubt adrenaline may be useful by itself, or as an adjuvant, in some cases of heart failure. The prick of a needle alone may also be useful. Possibly adrenaline should always be used along with heart massage, as in Mr. Girling Ball's case, but, of either alone, I believe heart massage is the more dependable in such cases. The surgeon must make up his mind quickly as to the extreme gravity of the case, and act early, if such extraordinary measures as heart massage or injections of adrenaline are to be of any avail.

It would perhaps be unwise to make any definite statement as to lines of treatment in such cases. The cause of the heart failure may be obscure and very different in one case from another. Even research would not promise much, because obviously it would first be necessary to reproduce syncope as it occurs on the operation table and in similar circumstances, which would be difficult.

Dumfries.

## NERVE ENLARGEMENT IN LEPROSY.

The diagnosis of advanced leprosy is not difficult, but very often by the time the disease is recognized the patient is permanently deformed and beyond the possibility of cure. The following three cases are published to lay stress on the importance of enlargement of nerves in leprosy. When a nerve is grossly enlarged it is not an uncommon experience to find that it is the only nerve affected; unless the possibility of one superficial nerve being grossly enlarged in leprosy is recognized the disease may not be diagnosed. Two out of the three cases reported were not diagnosed.

Case 1.—An Indian male complained of a swelling on the inside of the arm; it was about an inch in diameter, and was attached to the ulnar nerve, which was extremely thick, but not to the skin; fluctuation could be elicited. Along the outer side of the left hand, in the distribution with anaesthesia. The history given was that a depigmented anaesthetic patch appeared on the outer part of the dorsum of the hand; this was followed about three months later by the appearance of a neuro-fibroma. On the diagnosis of leprosy being made the patient was frightened, and went to another doctor, who, being doubtful of the diagnosis, found an area of depigmented anaesthesia. On the diagnosis of leprosy being made the patient was frightened, and went to another doctor, who, being doubtful of the diagnosis, found an area of depigmented anaesthesia. On the diagnosis of leprosy being made the patient was frightened, and went to another doctor, who, being doubtful of the diagnosis, found an area of depigmented anaesthesia.

Case 2.—A well-to-do Indian male, who had been in a good leprosy hospital for some time with extensive anaesthesia along the ulnar aspect of the right hand, and depigmented patches on the back, complained of acute pain and swelling of the ulnar nerve, which was very thick and very tender and tense. The skin near the internal epicondyle became red and hot, and as an abscess was suspected the nerve sheath was opened; nothing, however, was found, except a very large thickened nerve. On treating by rest in a splint, and 10 grains of phenacetin at night, (30 grains every four hours), and the acute reactions the patient was able to use his hand again. During the acute reactions he subsequently restarted, and the patient improved considerably. The ulnar nerve, however, was so grossly affected that permanent changes set in as the result of the formation of scar tissue in the nerve sheath.

Case 3.—A Burmese had had leprosy for three months so far as he knew. He complained of a swelling in the neck, which was found to be an enormously enlarged great auricular nerve; it was as thick as the little finger; the swelling was uniform down to the point where it disappeared behind the sterno-mastoid muscle; it was hard and tender to pressure, but there was no fluctuation. In addition, there was a raised erythematous patch

over the right eyebrow, and another similar rash at the angle of the nose. On examination of these areas for *Microbacterium leprae* a few were found. The nasal secretions, however, were not positive.

While enlargement of the great auricular nerve is common in India, Burma, and Siam, this is the largest I have yet seen. In other countries, particularly the Philippines, enlargement of the great auricular nerve is not commonly seen to any extent. Case 3 was not diagnosed as leprosy at first; therefore it is important to look upon any enlargement of a superficial nerve with suspicion in countries where leprosy is endemic.

Medical Secretary for the Mission to Lepers.

## NITROUS OXIDE ANAESTHESIA: STATUS EPILEPTICUS: LUMBAR PUNCTURE: RECOVERY.

The paper by Professor Ernest Glynn in the JOURNAL of May 29th (p. 895), reporting a death due to fulminating pneumonia after nitrous oxide anaesthesia, has recalled the following case to my mind.

A girl, aged 14 months, on June 4th, 1925, attended the outpatient department of the David Lewis Northern Hospital, Liverpool, with a small submental abscess. At 6.15 p.m. nitrous oxide anaesthesia was induced at the urgent request of the parents, but before the incision could be made the child entered into a state of status epilepticus. I admitted the child to the children's ward at 7 p.m. A hot mustard bath was given, and 6 ounces of normal saline with 1 ounce of glucose and 1 drachm of brandy were administered by the rectum. As the fits continued I withdrew, at 8.15 p.m., by lumbar puncture, 15 c.cm. of cerebro-spinal fluid under pressure. Chlorotone gr. v was given by the mouth. At 11 p.m. the temperature was 107° and the child vomited twice, a trace of blood being present. Tepid sponging was resorted to. A rectal enema (the other had not been retained) produced only a clear fluid result. At 2.30 a.m., as the fits continued, the same dose of chlorotone was repeated and chloroform anaesthesia induced. The patient slept for four hours, and at 9 a.m. was greatly improved and without an anaesthetic, but on June 9th nystagmus to the left and twitching of the left side occurred; on the following day the hands assumed the accoucher position. Acetone was present in the urine and glucose was being given at this time. At 5 p.m. 20 c.cm. of cerebro-spinal fluid were withdrawn under pressure. Neither this nor the previous specimen contained organisms; the Wassermann reaction was negative. Under treatment with chlorotone, calcium lactate, and glucose the patient improved, and a few days later was discharged in good health.

The case appears to add weight to the rule that anaesthetics in very young children are best avoided, if possible. I am indebted to Dr. J. Murray Bligh, physician to the department for children's diseases, for permission to publish this case.

C. W. HEALEY, M.C., M.B., M.R.C.S.  
Liverpool.

## RASH IN SCARLET FEVER DELAYED TILL THE FIFTH DAY.

The following remarkable case of delayed appearance of rash in scarlet fever is considered to be of sufficient interest to merit publication.

A child, aged 2½, was admitted to St. Mary's Hospital, Paddington, on June 7th, for cleft palate. Before the operation could be performed the ward had to be closed on account of an outbreak of measles. Further cases occurred and the ward remained closed. No visitors were admitted. On July 2nd the patient had a temperature of 105°, which was maintained, with slight variations, for five days; on the fifth day it dropped slightly, and a faint erythematous rash appeared chiefly on the legs, abdomen, and back. There was marked circumscribed pallor, some evidence of sore throat, and the child had the general appearance of a case of scarlet fever. The rash apart from its distribution, was typical, and I sent the child to the fever hospital. Next day (July 8th) I telephoned to the medical officer, who informed me that the rash had developed into well marked distribution of scarlet fever, and was beginning to peel, and that there was no doubt about the case being one of scarlet fever.

The interesting point, of course, is that there were no signs before the fifth day, except the temperature. I have never before heard of a rash being delayed so long as this. The child was well examined every day.

## Reviews.

### LEAD POISONING.

It has been known for some time that a band of workers in Harvard University and the Massachusetts General Hospital, headed by Dr. AUB, was trying to solve some of the problems connected with lead poisoning. The monograph on *Lead Poisoning*<sup>1</sup> is the outcome of their labours, and is an excellent illustration of what team work can accomplish. Plumbism is an interesting study, but with too many ramifications for any one individual student to follow up. Gaps in knowledge are being gradually filled, and to that the researches of Dr. Aub and his co-workers have materially contributed. The subject is approached by them more from the chemical and physiological points of view than from the clinical. The inquiry is mainly concerned with the reaction of lead in the body. There is generous recognition in the book of the work done by British, French, and German writers, also by American contributors, in the field of industrial plumbism.

The detection of lead in inorganic compounds is, chemically speaking, easy, but the same cannot always be said when the metal is combined with organic material. Before tests can be applied the organic material must be destroyed. Sulphuretted hydrogen may thereafter throw down a black precipitate in an aqueous solution, but if serum be present it will only give a wine-red colour. Yet the authors maintain that when the technique described in the monograph is applied, 1 part of lead in 10,000,000 parts of urine may be detected. Various methods of testing for lead are described, including the colorimetric, the electrolytic, the chromate, and the microchemical.

Most of the ordinary lead compounds are soluble in the gastric juice, but in varying degrees: the carbonate has a solubility of 40 per cent., sulphate 9.5, and natural sulphide 2.5. These varying solubilities indicate how readily plumbism may occur when the metal enters the body by the gastro-alimentary canal, but while this is a common route probably the larger bulk of industrial lead poisoning is a consequence of absorption of dust through the respiratory tract. The fine dust, for example, given off during the dry sand-papery of a lead-painted surface is, when inhaled, a fruitful source of poisoning. The amount of lead in the blood at any time is small, so that its isolation and identification are difficult. The authors lean to the view that the absorbed lead is present in the form of colloidal phosphate rather than albuminate, as suggested some time ago by Sir Thomas Oliver. The slow accumulation of lead in the body and its deposition in the bony tissues provide the opportunity to the authors of drawing attention to the formation of lead phosphate. They have found that under equilibrium conditions di-sodium phosphate and lead chloride react to form di-lead phosphate; also that, when the two reacting substances are first mixed, tri-lead phosphate is formed. The presence of any localized acid product transforms the tri-lead salt to di-lead phosphate. It is these two salts—the tri-lead and di-lead hydrogen phosphates—which are of interest, since the one can be transformed into the other within the body, and thus influence the health of the individual.

Most are familiar with the fact that lead can be stored within the body without giving rise to symptoms, until through some defect in the diet, or the presence of infection, the reaction of the tissues becomes altered, and a larger amount of lead appears in the circulation. In the blood of animals fed with lead salts only a few thousandths of a milligram may be found so long as the animal remains in apparently good health; but when acidosis develops the amount of lead circulating in the blood becomes increased. In a fatal case of lead encephalopathy in a man there were found 2.8 mg. of lead per litre of blood, equal to 3.64 mg. of tertiary lead phosphate. The Harvard research workers are of the opinion that the bulk

of the colloidal lead phosphate is held by the plasma, and that little is carried by the blood corpuscles. In the case of a rabbit poisoned by lead the amount of lead in the blood amounted to 0.75 mg.; of this 0.53 mg. was in the plasma and 0.16 mg. in the red corpuscles; in other words, 80 per cent. was held by the plasma. When a soluble salt of lead is added to blood serum a precipitate is formed which the authors state may probably be lead albuminate, but this white precipitate soon dissolves, for it is sensitive to changes in acidity. Prévost and Binet in 1889 taught that the lead present in the bones of animals experimentally poisoned by lead was in the form of phosphate. Owing to the small amount of the metal present—10 to 20 mg. in 150 grams of bone—Aub and his colleagues admit that it has been impossible to separate the lead compound so as to identify it absolutely as phosphate. The chemical problems connected with this aspect of the question have been, however, most carefully studied by them.

The three channels by which lead enters the system (the skin, respiratory tract, and alimentary canal) are considered and contrasted. While the principal channel is the respiratory, it is difficult to exclude simultaneous absorption by the alimentary canal. When absorbed through the respiratory tract lead gains entrance almost directly into the blood stream, but when swallowed part of it is eliminated in the faeces, while soluble particles which are absorbed may be held up in the liver. It is thus, as Legge properly maintains, that work carried on in dusty lead processes becomes so dangerous; moreover, poisoning through the respiratory tract occurs more rapidly.

It is in the skeleton, as already stated, that Aub and his colleagues have found lead deposited in largest quantities. The circumstance is interesting, for, although it might be expected that the metal would become specially fixed in the marrow, this is not the case, since the greater amounts were found in the solid portions of bone, usually in the form of tertiary phosphate. The authors confirm the statement made by previous writers as to the comparative absence of pathological changes observable *post mortem*, even where well marked symptoms were in evidence during life, and they affirm that incorrect conclusions have frequently been drawn from autopsies revealing lesions characteristic of conditions other than lead poisoning. It is an equally interesting circumstance that, while the liver bears the brunt of comparatively large quantities passing through it, the opinion expressed by Oliver is confirmed that *post-mortem* examination of the liver by the naked eye reveals no changes which can be regarded as specific for lead. Mention is made of the minute haemorrhages found by Mott, Legge, Goadby, and Courtney in the perivascular spaces in the brain; also of the examination of the cerebrospinal fluid by Mosny of the Hôpital St. Antoine, Paris, and by Malloizel. Experimentally lead is shown to alter rather the surface of the red blood corpuscles than to exercise any special influence upon their contents. While "stippling" of the red corpuscles is dealt with, the presence of punctate basophilia in the blood cannot be regarded as a specific sign of plumbism. It occurs in pernicious anaemia, leukaemia, and in the anaemias associated with the presence of neoplasms in the body; but in these conditions basophilia is slight compared with what it is in lead poisoning. The authors describe the symptomatology of plumbism, and allude to Ocker's treatment by the daily intravenous injection of sodium hyposulphite (0.6 gram); they state also that in their hands the intravenous injection of calcium chloride, 15 c.cm. of a 5 per cent. solution, slowly administered, promptly relieved colic.

It is appropriate that the closing chapter of the book should have been written by Dr. ALICE HAMILTON. She deals with the prevalence of industrial lead poisoning in the United States. Her work in this direction is not less well known and appreciated in Great Britain.

The book is a record of investigations thoughtfully organized and carefully carried out. As these cover ground hitherto largely untouched, valuable information has been gained which will be of the greatest assistance to all who are interested in the problems of lead poisoning, and so that end the well prepared and extensive bibliography will also contribute.

<sup>1</sup> *Lead Poisoning*. By Joseph C. Aub, Laurence T. Fairhall, A. S. Minot, and Paul Reznikoff. With a Chapter on the Prevalence of Industrial Lead Poisoning in the United States by Alice Hamilton. *Medicine Monographs*, Vol. VII. London: Baillière, Tindall and Cox; Baltimore: The Williams and Wilkins Company. 1926. (Med. 8vo, pp. x + 265; 35 figures. 18s. net.)

RADIATION IN EMBRYOLOGY AND  
GYNAECOLOGY.

PROFESSOR DORLAND and Dr. HUBERT of Chicago have produced a very beautiful volume entitled *The X-Ray in Embryology and Obstetrics*.<sup>2</sup> Dr. George W. Bartelmez contributes a short introductory chapter on the nature of the x rays and upon their physiological action. The authors then proceed to a general discussion of the influence of x rays and allied radiations upon living tissue. It is important to notice that, in the view of these experts, their application in pregnancy is not without an element of danger to the unborn infant. Naturally, the danger is greatest where radiation is employed in the early months. Radiation during late pregnancy is not likely to produce gross deformities or abnormalities in the child at birth, but it may ultimately cause retardation of growth subsequent to birth. A short exposure for purely photographic purposes in the later weeks is not likely to have any bad effect upon the child. In the next six chapters the development of the embryo as revealed by x rays is discussed systematically. This is a most valuable portion of the work, and will be read with interest and profit by surgeons and physicians, as well as by obstetricians and radiologists. The x-ray photography of the vascular system in different organs provides a fascinating study. The employment of x rays in the investigation of the maternal pelvis is next discussed, and various methods are explained and illustrated. The diagnosis of normal and abnormal pregnancy and the various forms of pelvic contraction are fully dealt with and illustrated. Then follows a chapter on the diagnostic value of x rays in teratogenesis, and several chapters upon different varieties of foetal monstrosities, with x-ray photographs, showing the nature of the skeletal deformities.

The volume, as has been said, is beautifully illustrated throughout, and the authors and publishers alike are to be congratulated on the illustrations. The authors appear to have based their conclusions on sound data, and do not attempt to claim too much. The result is that their book is stimulating, and should do much to encourage further study along similar lines. It is a mine of information into which workers in all branches of the medical profession may delve with profit.

## NUTRITION AND METABOLISM.

WE have received a copy of *Lectures on Nutrition*,<sup>3</sup> which contains a series of six given by well known authorities at the Mayo Foundation and the Universities of Wisconsin, Minnesota, Nebraska, Iowa, and Washington (St. Louis). As is pointed out by Dr. Louis B. Wilson in the introduction, the lectures contain a large amount of fresh and interesting information without attempting to cover in detail the entire subject of nutrition. Dr. F. G. Benedikt, who contributes the first lecture, entitled "The measurement and significance of basal metabolism," shows that basal metabolism, while undeniably in a state of flux and subject to the influence of factors other than those of age, is a very good index of the general state of vital activities, and as the result of the introduction of simplified methods can be determined by a much simpler technique than that for counting the blood corpuscles. In his lecture on "Problems of metabolism" Professor Graham Lusk, after an interesting historical introduction in which he jocosely remarks that inadequate knowledge of the older literature is one of the problems of metabolism requiring treatment and cure, discusses the variability of heat production, the relation of heat production to surface area, the effect of protein and protein derivatives on heat production, and the metabolism of fat and carbohydrate, terminating with the practical application of glucose in cases of nervousness and prostration. Professor Eugene F. Du Bois, who in the following lecture discusses the proportions in which protein, fat, and carbohydrate are metabolized in disease,

especially in typhoid fever, tuberculosis, and circulatory and renal disorders, maintains that there is no valid reason for the protein-free diet sometimes advocated in the two last named diseases. Muscular activity and carbohydrate metabolism form the subject of a lecture by Professor A. V. Hill, who presents several instructive charts indicating the effect of exercise on metabolism. In his lecture on our present knowledge of vitamins, Professor E. V. McCollum gives an admirable survey of the subject, and indicates the role which vitamins play in influencing metabolism. The relations between fertility and nutrition are discussed in the last lecture by Professor H. McLean Evans, who brings forward evidence of the existence of vitamin E, the absence of which gives rise to sterility. A bibliography of recent literature is appended to each lecture.

## THE MIND OF THE YOUNG CHILD.

"A PSYCHOLOGICAL outline of normal development from birth to the sixth year, including a system of developmental diagnosis" is the subtitle of a book entitled *The Mental Growth of the Pre-School Child*,<sup>4</sup> written by Dr. ARNOLD GESSELL, the director of the Yale Psycho-Clinic. In his introductory remarks he states that in observing the young child his object is to bring the familiar and the scientific into closer relation. The purpose of this rather bulky volume is to report the data gathered during investigations on some 500 children. The material is arranged in four parts, of which the first three are mainly descriptive and interpretive. A description is given of the gradual development of motor power, language, adaptive behaviour, and personal-social behaviour, and reproductions of action photographs show various stages in development. Part IV deals with practical applications in developmental diagnosis, and an attempt is made to devise an adjustable clinical instrument. Though the physical needs of school children have received considerable attention, it is only now being realized that the needs of the pre-school child, both physical and psychological, should receive more attention. Behaviour is considered as the functional index of developmental maturity. The neurone pattern concept is used as a formula to assist interpretation and observation. "The mental development of a baby becomes somewhat less elusive if we regard the progress of his attainments and his propensities as the maturation of both inborn and acquired neurone patterns." Interest in development is universal, and now, thanks to the rapid multiplication of infant welfare centres, interest in the health of children is increasing. It is probable, therefore, that in the near future health examinations will broaden into developmental examinations, and include a psychological inquiry into the health, habits, dispositions, capacities, and personality traits of the child. Helped by medical teaching, parents may then be able to assist the child to achieve mental as well as physical health. To those interested in such possible developments the summary of data given in this book will prove useful.

## NOTES ON BOOKS.

Dr. W. J. STONE's handbook on *Blood Chemistry Colorimetric Methods* is addressed to the general practitioner. Since a second edition<sup>5</sup> has followed the first in two years we must believe that the author has not wooed in vain, though we find it difficult to believe that any considerable body of medical men will be persuaded to institute their own laboratories and adventure on a path which is as yet poorly prospected. The new edition has swollen both in bulk and in price. The price, indeed, will appear high to those whose traffic in medical books has not extended to those made in America, since the book is but a modest labour, and its production, though attractive, is not—it has no cause to be—sumptuous. The usual colorimetric methods for the determination of the chief constituents of blood are included, together with clinical comments on diagnosis. Particularly we note a discussion

<sup>2</sup> *The X-Ray in Embryology and Obstetrics*. By W. A. Newman Dorland, A.M., M.D., F.A.C.S., and Maximilian John Hubert, M.D., F.A.C.R., F.A.O.P. London: H. Kimpton. 1925. (7x9), pp. xv+420; 254 figures. 50s. net.)

<sup>3</sup> *Lectures on Nutrition*. 1924-25. Philadelphia and London: W. B. Saunders Company. 1926. (Post 8vo, pp. 243; 22 figures. 12s. net.)

<sup>4</sup> *The Mental Growth of the Pre-School Child*. By Arnold Gesell, Ph.D., M.D. New York: The Macmillan Co.; London: Macmillan and Co., Ltd. 1925. (Demy 8vo, pp. x+447; 225 figures. 15s. net.)

<sup>5</sup> *Blood Chemistry Colorimetric Methods*. By Willard J. Stone, B.Sc., M.D. Introduction by George Dock, M.D. Second edition, revised. New York: F. B. Hoeber, Inc. 1925. (Med. 8vo, pp. x+123; 7 figures. 3.25 dollars net.)

of the diagnosis of impaired kidney function, useful dietary tables for the control of various metabolic disturbances, and comments upon the management of the diabetic by aid of insulin and diet. The last is based upon the principle of the ketogenic-antiketogenic balance.

The appearance of a second edition of Professor SCHRÖDER'S *Lehrbuch der Gynäkologie*<sup>6</sup> within four years of its publication testifies to the popularity it has achieved. Its success would appear to be thoroughly justified, as it deals scientifically with the whole subject of gynaecology. It is profusely illustrated, and the illustrations are for the most part good. Numerous coloured plates, reproduced with remarkable faithfulness, add very much to its value. Gynaecological pathology is well handled, but treatment does not receive very full discussion, and there is no attempt to describe operative methods. This is all the better, as there are already many books dealing with that more or less exclusively. Suffice it that Professor Schröder's work will certainly be a standard one for many years to come for all workers in the subject in all countries.

In their *Atlas of Midwifery*<sup>7</sup> Mr. COMYNS BERKELEY and Dr. GEORGES DUPUY have collected into one comparatively small volume a series of 256 pictures which illustrate practically all the points in connexion with the teaching of midwifery that lend themselves to pictorial representation. They are arranged according to the usual sequence of teaching. The first series deals with the anatomy of the female reproductive organs; the next with conditions of pregnancy; the third with labour; and the fourth with the newborn child; lastly there is a small series of radiograms. There is really nothing new in the illustrations, which are almost all more or less familiar, or at least of a familiar type; but there is no doubt that to have them collected in this way will be a convenience for teachers and for students. For nurses training for their C.M.B. examinations merely to turn over the pages of this atlas, and to read the short explanatory legends attached to each figure, is to obtain an interesting and rapid revisal of the whole subject. The authors, in our view, have done a distinct service in publishing this little volume.

Two small but charmingly written books by women doctors from the Far East give stories culled from their experience in the service of the Church of England Zenana Missionary Society. *Flashlights on Chinese Life: Yellow Dragon Street and other Stories*,<sup>8</sup> by the late Dr. MABEL PANTIN (1867-1926), in spite of its rather vivid title and the bizarre dragon in yellow and red on the cover, shows the manifold charity and touches of quiet humour of this devoted woman, who died shortly after writing it, having had twelve weary years of illness which, however, did not damp her wonderful vitality and keen enjoyment of life. Her portrait—a fine face—forms the frontispiece, and the scenes of her labours are illustrated in the text. It contains an unsigned appreciation of Dr. Pantin, and is divided into two parts, about Fukien and Hunan respectively. In *A Woman Doctor on the Frontier*<sup>9</sup> Dr. CHARLOTTE S. VINES tells stories of her life and patients in India, with its infinite variety of native character and its rapid climatic changes; it is written in a simple and appealing style, as much as to say, "Come over and help us." Her reference to the late Dr. Katherine Gregg, who lies among "the heroes of the frontier," surrounded by "the everlasting hills," reminds the reader of the sacrifices, all unnoticed in this busy world, that these women doctors cheerfully make in the mission field. Told with dramatic force and pathos, these stories will no doubt make the woman reader consider whether she is called to follow such an active and beneficent life.

<sup>6</sup> *Lehrbuch der Gynäkologie*. Von Dr. Med. Robert Schröder. Zweite Auflage. F. C. W. Vogel. 1926. (Sup. roy. 8vo, 1, bound, M.39.)

<sup>7</sup> *An Atlas of Midwifery*. Comyns Berkeley, M.A., M.C., M.D., Cantab., 1, and Georges M. Dupuy, M.D., London: 1926. (Med. 8vo, pp. viii+160; 248 figures, and 8 in x-ray supplement. 7s. 6d. net.)

<sup>8</sup> *Flashlights on Chinese Life: Yellow Dragon Street and other Stories*. By Mabel Pantin, L.M.S.S.A. London: Church of England Zenana Missionary Society. 1926. (5½x8, pp. 55; frontispiece and 16 illustrations. 1s. 6d.)

<sup>9</sup> *A Woman Doctor on the Frontier*. By Charlotte S. Vines, L.R.C.P. and S.E.D. London: Church of England Zenana Missionary Society. 1925. (Cr. 8vo, pp. 78; frontispiece. 1s. 3d.)

## PREPARATIONS AND APPLIANCES.

### A Cannula for Intravenous Injections.

Dr. A. E. ROCHE (London, W.) has devised a cannula for intravenous injections, which is a modification of Clayton-Greene's tapering blunt-pointed cannula, and is made by Messrs. Weiss. He writes: "Although Clayton-Greene's cannula for ease of introduction is superior to the large bulbous-ended cannulae, which are too large for introduction into the collapsed vein, and to sharp-pointed instruments, which have occasionally caused vexation by

piercing the opposite wall of the more or less empty vein, yet it has, he thinks, the following disadvantages: Since the tip of the instrument is closed and the fluid leaves the cannula by a lateral opening about one inch up the shaft, intravenous injections have sometimes been found impossible, either because the vein is so small that the cannula opening was still outside it when the tapering shaft had plugged the opening, or because a Y-shaped division of the only available vein obstructed the complete entry of the cannula. The passage of the fluid was often stopped by the lateral hole in the cannula coming tightly

against the vein wall, necessitating rotation in order to restart the flow. The cannula may bend or break at the site of the lateral opening. The modification devised by Dr. Roche retains the advantageous blunt tip and tapering shaft of Clayton-Greene's cannula, but has no lateral hole to weaken it; the fluid flows from the terminal oblique opening, and is thus not liable to obstruction by the wall of the vein. Dr. Roche adds that the advantages claimed for the modification have been fully substantiated in practice, using either saline solution or citrated blood.

## ADMISSION OF WOMEN TO THE BRITISH MEDICAL ASSOCIATION.

Mr. R. G. HOGARTH, in his Presidential Address at the Annual Meeting at Nottingham, made reference to the fact that it was at the last preceding meeting in Nottingham (1892) that the vote admitting women to full membership of the Association had been adopted by an overwhelming majority, only three or four hands being held up against it in a meeting of about 300. The resolution was moved by the late Dr. J. H. Galton of Upper Norwood, then a member of the Council, and held in very high esteem by all members of the Association. It was seconded by Mrs. Garrett Anderson, M.D., who had been elected a member before the restriction was imposed. Of the speakers none opposed it.

The following letter has been addressed to the President, Mr. Hogarth, by some medical women who desire to express their appreciation of his reference.

August, 1926.

DEAR MR. PRESIDENT,

We, the undersigned medical women attending the Annual General Meeting at Nottingham, feel we cannot allow to pass unnoticed your timely and much appreciated reference in your Presidential Address to the fact that it was at the last Annual General Meeting held in Nottingham in 1892 that medical women were admitted to the British Medical Association.

We wish to express our deep sense of what we owe to Dr. J. H. Galton, who proposed the resolution, Mr. Lawson Tait, Dr. W. H. Ransom of Nottingham, and Dr. Elizabeth Garrett Anderson, as well as to all those who helped them in attaining this privilege for us—a privilege which Sir Victor Horsley did so much to maintain in later years. We feel that this important step taken by the British Medical Association has been amply justified by the benefits which have accrued both to the British Medical Association and to medical women.

We are, Mr. President,

Yours very truly,

## THE INTERNATIONAL PHYSIOLOGICAL CONGRESS AT STOCKHOLM.

(Concluded from page 517.)

The twelfth International Physiological Congress ended with a meeting in the Hall of the University of Upsala, to which the members were taken from Stockholm by a special train. Here, after an address of welcome from the Rector of the University, invitations for the next congress, in 1929, were read from Milan and the United States of America; after a little discussion the meeting decided to accept that from America.

Upsala, the oldest and largest university in Sweden, possesses spacious, well equipped laboratories of physiology, anatomy, pharmacology, and chemistry. Stockholm has no university, but several independent institutes, notably the Caroline Institute of Medicine, which has small but exceptionally well equipped laboratories. The only other university in Sweden is at Lund, which, unfortunately, there was no opportunity to visit. The meetings of the congress were all held in the Stockholm City Hall and the demonstrations in the Caroline Institute.

### *The Parathyroid Hormone.*

Of the papers read bearing more or less directly on medicine, perhaps the most important was that of Collip (Edmonton, Canada) on the parathyroid hormone. His conclusion is that tetania parathyreopriva is due to a hypocalcaemia, and that injection of an extract of the parathyroid gland increases the concentration of calcium in the blood and arrests the tetany. Injection of the extract into normal animals sets up a hypercalcaemia and results in death in forty-eight to seventy-two hours; large amounts of calcium are then found in the kidneys, heart, and liver, as well as in the blood. Collip recommends as treatment for tetany, both post partum and resulting from parathyroidectomy, the raising of the blood calcium to a normal figure by injection of parathyroid extract, and then its maintenance by calcium lactate.

### *Diabetes.*

Several papers were read on the subject of diabetes; notable among them were that by Peserico (Milan), who has shown conclusively that the tissues of a diabetic animal can burn sugar; and those by Mansfeld (Pérez) and Voronoff (Paris) on the operative treatment of diabetes. Mansfeld prevents about one-third of the pancreas from secreting the digestive juices, with the result that the internal secreting glands hypertrophy, so that normal animals operated on in this way get a hypoglycaemia. Voronoff has succeeded in grafting the pancreas of one dog into another previously depancreatized and with severe glucosuria; complete recovery resulted.

### *Sex Reversal.*

Pézar (Paris) reported an interesting observation with regard to sex reversal in fowls. By implantation of varying amounts of testicular substance into ovariectomized hens, he has shown that there is always a complete sex change or none at all—that is to say, that implantation of half the amount of testicular substance that is just sufficient to give a sex reversal does not give a partial reversal; it has no effect. The sex of the birds was very ingeniously determined by implantation of a comb on the back—in a male the graft takes and the comb grows to a full size; in a female it atrophies completely.

### *Ovarian Transplantation.*

Voronoff and Didry (Paris) read a report on what may prove to be a very important piece of work, although considerable scepticism was expressed at the meeting. They have transplanted a human female ovary into a female chimpanzee, previously ovariectomized, with the result that normal menstruation returned. They then fertilized this chimpanzee with human sperm, and menstruation ceased, so that they now await the birth of a human child. Even if this actually occurs there is no doubt that confirmation in other laboratories will be required before the explanations given can be fully accepted.

### *Some Other Papers.*

Koppanyi (Chicago) gave an account of experiments showing that regeneration of the central nervous system is possible in fish, larvae of amphibia, and embryonic and young rats. Mann (Rochester) read a summary of his observations on the results of extirpation of the liver, in which he states that there is a decrease in blood sugar, no formation of urea or deamination, uric acid is not destroyed, and that there is no change in the formation of bile; and Howell (Baltimore) described the results of his attempts to determine the constitution of the anticoagulant heparin. It appears to be largely glycuronic acid, and there is no nitrogen or phosphorus. He stated also that haemophilia is due to the platelets not breaking up on coming into contact with foreign bodies; there is no lack of prothrombin.

### *Demonstrations.*

The two most important demonstrations were those of Mrs. Kerridge (London) on the glass electrode method of determining the hydrogen ion concentration of solutions, and of Yandell Henderson (New Haven) on the ethyl iodide method of determining the rate of circulation of the blood. The determinations by the glass electrode are rapid, taking about two minutes, are independent of the nature of the solution, and are very accurate. The apparatus is portable, and is to be put on the market by the Cambridge Instrument Company.

### *Distractions and Gratitude.*

As a relaxation the congress made an expedition to Saltsjöbaden, the pleasure resort of Stockholm—a place of pine trees and granite islands, on an arm of the Baltic sea—in two specially chartered steamers. Here the members bathed, dined, and danced.

In this way Stockholm catered magnificently for our amusement as well as for our instruction, and every member of the congress owes the city a deep debt of gratitude for the wonderful way he was entertained.

L. E. BAYLISS.

## THE HEALTH OF LONDON, 1925.

### REPORT OF THE LONDON COUNTY COUNCIL.

THE reports of the medical officer of health and of the school medical officer of the London County Council for 1925 have been published in one volume as Volume III (Part) of the Annual Report of the Council. They have been prepared by Dr. Menzies in collaboration with Sir William Hamer, and the occasion of the latter's retirement at the end of 1925 has prompted the introduction, into the report of the medical officer of health, of a short review of the Council's public health work during the period of its existence and since the appointment of its first medical officer of health, Sir Shirley Murphy, in 1890. The late Dr. Niven, on his retirement three years ago from the post of medical officer of health for Manchester, prepared *Observations on the History of Public Health Effort in Manchester* during the period 1894-1923, and the opportunity is taken to compare and contrast the conditions in London with those of Manchester and to refer to points of resemblance and difference in the health problems of the two cities during these two similar periods.

### VITAL STATISTICS.

The population of London in the middle of 1925 was estimated at 4,612,000. The marriage rate was 17.2 per 1,000, the birth rate 17.9, and the death rate 11.9. With the exception of abnormal fluctuations during and immediately after the war, birth and mortality rates have steadily declined during the last fifty years, the decline in the birth rate being particularly rapid since 1900. But the most striking statistical result is the remarkable decrease in infantile mortality. For the period 1841-1925 the mean of the rates is 141.7 per 1,000 births. In 1899 the rate was 170 per 1,000, but from then onwards it has steadily fallen to 61 per 1,000 in 1923, 69 in 1924, and 63 in 1925. These figures indicate the influence of collective sanitary effort

<sup>1</sup> London County Council: Annual Report of the Council, 1925. Vol. III (Part): Public Health (including the Reports for the Year 1925 of the County Medical Officer of Health and School Medical Officer). (10 x 6½ in., pp. 170.)

on the public health, and especially of the maternity and child welfare activities of recent years.

An analysis is made and a chart introduced of the mortality from different groups of disease since 1841. The chart, however, is not attractive. The contours are on different scales for different groups, and are not based on death rates per 1,000 of population, but on the actual deaths as registered, so that its value for comparative purposes is negligible. Deaths from diseases of the circulatory system and cancer, and to some extent from influenza and pneumonia, have steadily increased, but this is attributed to greater accuracy in diagnosis and certification and to change of fashion in nomenclature more than to actual increase.

#### INFECTIOUS DISEASES.

Some interesting facts are to be gathered from this section of the report. In describing a comparatively slight outbreak of small-pox in Bethnal Green in 1925 the report states that in a school in the heart of the affected area 799 out of 1,370 children had never been vaccinated, and, when the public vaccinator visited the school, the consent of the parents to vaccination was obtained in 27 cases only. There were 304 cases of encephalitis lethargica as compared with 605 in 1924. The case mortality showed considerable fluctuation, however, being only 22 per cent. in 1924 as compared with 40 per cent. in 1925.

#### Influenza.

A considerable amount of space is devoted to a discussion on periodicity and forecasts of influenza epidemics. The conclusion arrived at is that although forecasts as long ahead as two years can be made the number of instances is too small to justify any reliance being placed on them. An hypothesis of a thirty-fifth week recurrence fails, by the authors' own confession, in several instances. Yet they indulge in forecasting the calamity of a prevalence of influenza about the end of 1926. The reservation of failure is comforting.

#### Typhoid Fever.

The epidemiology and causation of typhoid fever are also discussed in a somewhat controversial criticism of American writings as compared with the London experience. The latter seems to favour the consumption of ungutted plaice and shellfish as the cause of enteric, the former polluted milk and water and healthy carriers. The discussion, however, leads nowhere, and appears unnecessary in a report of this kind. All it tells us is that the London experience of typhoid differs in some respects from the experience of other communities. For example, the once familiar autumnal increase has practically ceased since 1912 in London, while still exhibited in other parts of England and Wales; and typhoid fever fails to show special incidence on the poorer areas. The actual number of cases notified in London in 1925 was 395 with 49 deaths, as compared with 410 and 53 deaths in 1924.

#### Tuberculosis.

The deaths from pulmonary tuberculosis show a rate of 0.95 per 1,000 of population in 1925. The rate has declined since 1922 and preceding years, when it exceeded 1.0 per 1,000. The number of cases notified in the London boroughs was 9,661 for all forms of tuberculosis and 7,554 for pulmonary tuberculosis. The number on the register at the end of the year, prepared in accordance with the Public Health (Tuberculosis) Act of 1924, was 39,551 pulmonary and 15,074 other forms. In the administrative section of the report an interesting and full account is given of the London County Council's tuberculosis scheme, together with a history of the movement which led up to it, and which commenced in 1909.

#### Veneral Diseases.

A page of special interest deals with the control of venereal diseases. Under the London and Home Counties scheme 5,502 cases of syphilis, 11,321 of gonorrhoea, and 279 of soft chancre, or a total of 17,502 new cases, voluntarily came for treatment at the hospital clinics. This is 779 fewer than in 1924, the decrease being almost entirely due to a reduction of 724 in cases of syphilis. The total attendances at the clinics amounted to 646,131, or 36 for each new case, a considerable advance as compared with

previous years. It is significant that the ratio of attendances in countries where there is compulsory notification of venereal diseases has never been greater than the London ratio with its voluntary system.

#### THE BACTERIOLOGICAL LABORATORY.

The remainder of the medical officer of health's report contains a report from the bacteriological laboratory by Dr. Graham Forbes, with some important details of the examination of cerebro-spinal fluid as an aid to clinical diagnosis in a variety of conditions of meningitis and cerebral lesions, and a special investigation of the role of the streptococcus in relation to throat infection and the transmission of puerperal fever and scarlet fever. The investigation was, however, too limited in extent to admit of definite conclusions.

#### REPORT OF THE SCHOOL MEDICAL OFFICER.

In an introductory note attention is drawn to the phenomenon presented by infantile mortality, to which reference has already been made, and to the influence on public health of the Education Act of 1870, which is considered to have operated mainly in developing in parents a sense of responsibility for the health and lives of their children. Seven important developments in connexion with school medical service were contemplated by the London County Council in 1925—namely, the examination of children leaving school, the extension of dental treatment, inauguration of centres for in-patient treatment of tonsils and adenoids, establishment of special ionization centres for treatment of ear disease, and further provision for remedial exercises, for open-air education, and for special medical services.

The report contains a mass of facts, too numerous to consider here, but of great interest and importance. It may be noted, however, in connexion with the report on rheumatic heart disease in children by the special subcommittee of the British Medical Association, published as a SUPPLEMENT to the JOURNAL of July 3rd last, that a special section is devoted to the manifestations of rheumatism in childhood. A spot map of London shows that the distribution of rheumatic children was chiefly in areas along the alluvial valleys marking the courses of old rivers running into the Thames. It has not been found possible in the present state of knowledge to suggest specific steps for preventing attacks of rheumatism. The most hopeful measures, it is considered, include greater attention to nose and throat ailments, improvement of housing conditions and home care, and special facilities for convalescent treatment, provision for which is totally inadequate at present. As regards school attendance, administrative action on the lines already worked out for the tuberculous child is recommended. All this confirms the conclusions arrived at in the British Medical Association Subcommittee's report.

Several statistical tables conclude the report of the school medical officer. It appears that the total number of routine inspections of children in elementary schools was 238,713; in addition 1,652 children were inspected in special schools. A considerable number of special inspections were also made; in 42,882 instances special notes were made, and in 33,475 the children were inspected collectively. In 159,388 cases re-inspections were made. The defects found at medical inspections in elementary and special schools are set out in a table, from which it appears that the most frequent condition found, at routine inspections, to require treatment was dental disease; the cases numbered over 70,000. Defective vision was noted in 26,000 children, and called for treatment in over 20,000. There were in addition about 2,600 cases of squint, and over 2,000 of them were recommended for treatment. The number of cases of enlarged tonsils was 20,417, of adenoids 3,168, and of cases with both enlarged tonsils and adenoids 4,493; of these the numbers requiring treatment were respectively 11,653, 2,235, and 3,780.

The reports form part of Volume III of the annual report of the Council for 1925, but there is a curious discrepancy between the table of contents and the text. The contents shows two chapters, XXI and XXII, whereas the text indicates that the whole report forms Chapter XXIII of the Council's annual report.

SATURDAY, AUGUST 21st, 1926.

## TUBERCULOSIS AND THE STATE.

MODERN governments are faced by two irreconcilable demands. On the one hand, there is the need for economy in order to repair the loss of wealth caused by the war; on the other hand, there is the continual demand for State support for various measures designed to improve the health and well-being of the community. Often enough the two demands are made by one and the same person; so that a taxpayer, anxious for some relief from his burdens, is found in the incongruous position of asking the State for money or officials to aid his pet scheme for social amelioration. In health matters it is probable that most of the schemes originate from members of the medical profession, who succeed in invoking the assistance of distinguished laymen in forming a society for the purpose of impressing upon the Government the need for action. We have recently published reports of various societies engaged in the prevention or cure of tuberculosis; and it may be useful to attempt a dispassionate review of the present position of this matter from the social aspect.

Tuberculosis is a disease which invites the attention of the social reformer. It is so widespread that there can hardly exist a family in which some instance of its ravages has not occurred. Its infective origin is well known, so that, theoretically, it should be capable of extinction; being for the most part a chronic disease, its extinction would result in a great saving of wealth to the community. But though the reduction in mortality has been very great during the last fifty years, the death rate from this disease still remains high, in spite of the concentrated efforts of many societies for some thirty years past.

It is possible that in the campaign against tuberculosis the advocates of a particular measure are apt to forget certain facts. In the first place, the mortality from the disease began to decrease long before campaigns were thought of, even before the cause of the disease was known. Was this reduction in mortality due to acquired immunity, to a change in the character of the disease, to better habits of the people, or to better conditions of life? The answers to these questions are of importance to the statesman called upon to decide whether he shall spend State money on the elimination of the disease. Secondly, the *Bacillus tuberculosis* is ubiquitous in all civilized communities; so much so that it is generally agreed that most of us have at one time or other been infected. Some of those engaged in antituberculosis campaigns appear to base their proposals on the supposition that the bacillus can be exterminated. The statesman is entitled to ask whether this is a practicable proposition. Thirdly, failure to remember the two previous facts has led to confusion between prevention and cure in the aims of the various societies engaged in antituberculosis campaigns. Let us try to enumerate the methods that have been advocated for combating the disease. At the conference of the National Association for the Prevention of Tuberculosis held recently at Glasgow Sir Robert Philip described the "actual place and function of the tuberculosis dispensary in the tuberculosis scheme." It is now forty years

since Sir Robert Philip conceived the idea of the tuberculosis dispensary. It is curious that after forty years' experience Sir Robert still thinks it clear that the principles effectively applied to other infective conditions are applicable likewise to the ubiquitous *B. tuberculosis*. The tuberculosis dispensary is admirable as a centre for diagnosis, for the treatment of ambulant cases, for the examination of contacts, and as a clearing house for other institutions engaged in treatment of the disease. Its only contribution towards the extermination of the disease is statistical; whereby also it may help to prove the ultimate futility of some of the other measures adopted. The tuberculosis dispensary "has collected," says Sir Robert Philip, "living proof of the universality of tuberculosis throughout the community." And his remark about hospital beds in former times applies still, possibly, to sanatoriums; "the small percentage [of patients] which attained admission enjoyed the available benefit for a relatively short period." Dispensaries have shown also the frequency of tuberculosis in children, and the spread of the disease by mass infection in crowded households. Yet even after all these years Sir Robert Philip is constrained to the view "that the ideal of the dispensary and its great possibilities are not realized everywhere."

If we examine sanatoriums from the point of view of the cure of the disease, it will probably be admitted that they have not fulfilled expectations. Sir Robert Philip says that the dispensary has proved "how valueless may be the result of short periods of residential treatment—as, for example, the classic three months in a sanatorium." It is for this reason that officers at sanatoriums continually demand very early cases. At an early stage no one can say whether the disease is likely to be progressive, or whether the case is one of those slight infections from which nearly all of us are supposed to suffer, and from which the majority of us recover in any case. Probably the real truth about sanatorium treatment is that, while of value to the individual, it is mainly educative; that it is expensive; and that from the point of view of prevention or the extermination of tuberculosis its value is small compared with the magnitude of the whole task.

From the statesman's point of view, however, the interest in sanatorium treatment is that it leads to a fresh demand. The navy, who has been mended to some extent in a sanatorium, is obviously unfit to return to navvymod. It becomes necessary, therefore, to provide training centres in order that he may learn some lighter job within the measure of his capacity for work. In this matter also confusion creeps in. The training is not only good for the community by affording the damaged man an opportunity for work; the work is also good for the individual and helps his betterment by giving him an object in life.

One feature of tuberculosis schemes is the appointment of Tuberculosis Care Committees. These are at present voluntary bodies which endeavour to supply some sort of supervision of the person who has been found to suffer from the disease, who may or may not have had a period of treatment at a sanatorium, with or without training in some occupation. Tuberculosis Care Committees have been somewhat perturbed lately by the proposal that they should find suitable work for patients from training centres, as is shown in the report of the employment sub-committee of the Joint Tuberculosis Council which was summarized on July 3rd (p. 20). The care committees find it difficult to steer between the Scylla of the man

who is incapable of making a success of his job and the Charybdis of the trade unions, who object to the competition of subsidized labour.

A further attempt to deal with tuberculous persons is found in colonies such as that at Papworth in Cambridgeshire. To such colonies the tuberculous man is transplanted with all his family; he is placed under hygienic conditions; he is watched and treated by a medical staff; and the products of his labour are disposed of in a commercial manner. In some places this method of treatment has been successful up to a point, although it is hardly to be expected that the venture can ever be a complete commercial success.

The methods of campaign which we have described have, speaking generally, a curative aim. Incidentally, of course, they may have a preventive effect in removing a potential source of mass infection from too close contact with his fellows. But the ubiquity of the bacillus must render any preventive effect comparatively ineffectual, and certainly enormously costly. There are other measures which offer some hope in prevention by attacking the bacillus at some of its main sources of origin, or by raising the resistance of the community to its invasion. No one doubts that better housing accommodation, more light and air, a pure milk supply, all help to check the growth of the bacillus, or at least to render resistance stronger. Probably these factors were instrumental in reducing the mortality before the germ was discovered. Latterly, however, more direct efforts have been made to render the host of the bacillus more immune. The unfortunate experiences of the use of Koch's tuberculin delayed researches in this direction enormously, though tuberculin has continued to be used for diagnostic purposes in cattle. Dr. Camac Wilkinson and his followers have always maintained that with proper supervision tuberculin is not only useful for the diagnosis of tubercle in the human being, but also has very marked curative effects. More recently we have had occasion to publish some of the results obtained by Calmette in Paris by pre-immunization with the bacillus Calmette-Guérin (B.C.G.).<sup>1</sup> Pre-immunization is defined as a vaccination, comparable with that produced by vaccinal viruses, but with the difference that it is bound up with the persistence of the vaccinating organisms in the lymphatic tissues of the immune subject. The vaccine is given by the mouth in three doses on alternate days, within the first ten days after birth. The reason assigned by Calmette for this limitation of time is that the intestinal mucosa of newly born animals easily absorbs bacteria, but loses this power in a few weeks. Experiments on calves and monkeys have, as we have already reported, yielded encouraging results, but the method is still in the preliminary stage, and Calmette writes with great caution about it. He has, however, consented to its use at a considerable number of tuberculosis dispensaries in France and in the French colonies. The possibility of arranging for a trial of it in this country is under consideration, but it would be premature at present to say more than this.

We have attempted a brief and impartial review of the various methods by which tuberculosis is being attacked. In doing so we have tried to bear in mind the information required by a statesman who is called upon to assist the experiments that are in progress. For throughout all the reports that we have examined there runs the thread of State assistance and subsidy;

and it is interesting to note that when government embark on large schemes of social amelioration each successive plunge in welfare schemes brings with it fresh difficulties. The tuberculous patient whose health has to some extent been mended in a sanatorium may need, and in perhaps the majority of cases does need, some more suitable occupation than his own. Training centres become necessary. When the course of instruction at a training centre is finished, the ex-patient needs a job. The local committee is asked to help in the difficult task of finding one for him; and when the job is found it seems clear, from hints in the reports, that the ex-patient sometimes makes a mess of it, and is once more thrown upon the State. Hence one of the causes of the development of settlements. The difficulty in settlements is to make them pay their way. The employees are damaged persons, and, as a rule, unfit for more than six hours' work a day. They are working in competition, not only with labour that is sound in wind and limb, but also with labour that is organized in trade unions with pronounced, and sometimes disputable, views on economics. And so there comes the appeal to the State for assistance. The granting of that appeal by the State naturally involves some voice in the management of the venture and the position is reached in which some begin to advocate absorption by the State. Without any wish to minimize the misfortunes of the consumptive, nor any desire to undervalue attempts to reduce or control possible sources of infection to the rest of the community, it is possible to feel doubts as to the wisdom of embarking on a large expenditure of State money, in what are, at present, experiments. Neither sympathy for the unfortunate consumptive, nor fears of extension of infection, should be allowed to lead to hasty and ill considered expenditure. As private ventures settlements, for example, are interesting experiments; in the hands of devoted enthusiasts they may, to some extent, be made to pay; in any case as experience is gained difficulties will be sifted out. With State interference it is possible that enthusiasm will evaporate, expenses increase, and a burden be added to the State without commensurate benefits. For it is evident that settlements can only touch the fringe of the tuberculosis problem, and that lavish expenditure upon them may cripple more remunerative enterprises for the benefit of consumptives. And behind the whole method of settlements, sanatoriums, and other attempts at curative measures there looms the question whether research should not be directed mainly to the production of resistance to the attacks of a ubiquitous and unextinguishable germ.

## MOTOR ACCIDENTS.

It is a commonplace to say that of the changes in the externals of life which anyone over forty can perceive, the transformation of road traffic is the most striking. Most of us can recollect the golden age of him now derisively termed the "push cyclist": it was between 1895 and 1904, when pneumatic tyres had become reasonably reliable and the mere cyclist was still a welcome, almost an honoured, guest in country inns. In those happy and not very far off times the cyclist was the king of the road, and there were even people who accused him of a selfish disregard of the comfort of other road users, and of an addiction to dangerous speed. For some years after 1904 touring with a bicycle on the main roads of England was still agreeable, but by 1910—in which

<sup>1</sup> BRITISH MEDICAL JOURNAL, March 27th, 1926, p. 531.

for the number of persons slain by mechanically propelled vehicles passed the five hundred mark— began to be, if not essential, at least desirable to choose secondary roads connecting important towns, and for the next three years the quiet cyclist developed a taste for road strategy; the good strategist as he who found an effective route by secondary roads without being actually forced to carry his machine over stiles or through quagmires. Such a man congratulated himself that he had better glimpses of the countryside than the mechanically propelled enemy who occupied the high roads in force. After the war those whose gluteal regions and nerves were not both of iron had sadly to realize that for the man or woman past 40 the "push bicycle" was not a suitable instrument of pleasant locomotion along any motor-infested roads for more than an hour at a time.

Like all revolutions this has had to be paid for in blood and, it is to be supposed, tears. There is no doubt about the blood, for while in 1904 only 171 deaths were attributed to mechanically propelled vehicles, in 1924 there were 2,990, giving a rate of mortality of 77 per million, the highest yet recorded. Two attempts to analyse this mortality and to point the moral have been made—one by Major P. G. Edge in a paper read before the Royal Statistical Society this spring and just published,<sup>1</sup> the other in the Registrar-General's Statistical Review of 1924.<sup>2</sup> The statistical study of this matter is a very much more difficult undertaking than the outsider might suppose. To set out the actual increase of mortality and to allocate the deaths to the type of vehicle responsible is easy enough and has been satisfactorily done in both the papers. The mere rate of mortality per million rose from 5 in 1905 irregularly to 14 in 1910, and then without faltering to 36 in 1914, and since the war has risen from 46 in 1919 to 63 in 1923 and 77 in 1924. In 1904 motor cars were responsible for 33 per cent. of the small total mortality due to mechanically propelled vehicles, and have pretty well kept station since they had 34 per cent. of the much larger total in 1924. Motor omnibuses—not a sensible factor in 1904—have shown very large variations, and, since 1920, have increased their percentage claim by one unit a year, from 6 per cent. in 1920 to 10 per cent. in 1924.

Owing to changes in the registration laws it is not possible to show over the whole period comparable ratios of deaths to registered vehicles, and, with the exception to be noted below, it is not possible to show the ratio of deaths to users of motor vehicles, which is evidently what one would like to know. To judge from one of Major Edge's tables, it would appear that there has been no consistent increase in the ratio of deaths to registered motor vehicles between 1906 and 1921 in England and Wales; the table he gives for the County of London is not, of course, relevant, since deaths within the county need not be caused by motor vehicles registered in the county.

The Registrar-General is able to make an approximate comparison of fatal accidents due to motor buses and trams within Greater London in terms of mileage. In 1921-23 the approximate mileage, in millions of miles, of buses was 361 and of trams 273; the numbers of passengers carried by the two types of vehicle were almost equal—in each case rather more than 3,000 million. Of fatal accidents re-

corded by the police, the buses were responsible for 226 and the trams for 91. In terms of either miles run or passengers carried, the trams were safer than the buses. The Registrar-General has also studied, in rather more detail than Major Edge, the age distribution of fatal accidents classified by type of vehicle, and brings out the interesting point that while, speaking broadly, motor car drivers kill other people, especially children, motor cyclists kill themselves and the girls behind. Thus of every 1,000 fatal accidents due to motor cars 310 happen to persons under 10 years of age, but only 63 of every 1,000 accidents associated with motor bicycles. Only 94 per mille of the deaths due to motor cars are of persons aged 20 to 35, but 368 per mille of the deaths due to motor cycles are in this age group. The motor lorry is relatively quite as fatal to children as the motor car, but the electric tramcar is less fatal than the motor bus.

The moral the Registrar-General draws is that "probably the greater safety of the tram is largely due to its ample braking power, which may also account for its special superiority at ages 10-20, those at which boys fall off bicycles in front of trams and buses. If so, it would appear that it is very largely to increase of braking power that we must look for decrease (relatively to mileage run) of the mortality under consideration. From this point of view the recent tendency to fit four wheel brakes on motor cars is of much importance, and should in time effect a considerable reduction in the disproportionate mortality at 5-10, since at this age especially it may be possible to avert a fatal accident only by full and timely use of ample braking power."

Major Edge, being less weighted by official responsibility, makes more revolutionary suggestions—namely, (1) compulsory examinations to determine physical fitness, technical skill, and driving capacity before the issue of driving licences; and (2) compulsory insurance of the vehicle against mechanical defect (including third-party risk). These suggestions did not commend themselves to such experts as took part in the discussion of his paper. The objections certainly read like those which are invariably made to any reform, but it is not for us, without technical knowledge, to judge whether they are or are not sound. We can follow the speaker who urged that technically competent drivers might be, and sometimes were, grossly inconsiderate road users, but we do not see how this leads to the conclusion that a technical examination is useless. Indeed, most of the arguments seem equally to favour free practice in medicine, the law, and every other occupation entrance upon which involves passing a technical examination. No sensible person ever supposed that such a qualifying examination ensured that the successful candidate should be an efficient surgeon, lawyer, or actuary; what has been claimed, and admitted, is that such a test does prevent the letting loose on the public of dangerously ignorant persons. Law, drugs, surgical instruments, and even figures, are certainly dangerous weapons in the hands of the ignorant, but a high-powered motor car is no toy, and observation of some of our country roads in the holiday season, supported by the Registrar-General's figures and a perusal of the reports of inquests, suggests that some fatal accidents are due to inefficiency.

It is not improbable that the present state of affairs is only a passing phase. Motor traffic has of course come to stay. Its commercial use will no doubt

<sup>1</sup> *Journ. Roy. Stat. Soc.*, LXXXIX, 1926, pp. 405-451.

<sup>2</sup> *The Registrar-General's Statistical Review for England and Wales for the Year 1924*. Text, pp. 104-111.

increase, but whether as a sport motoring will be permanent is perhaps doubtful; indeed, just as the car has made the main roads unpleasant for the bicycle, so the lorry, charabancs, and motor buses may push the small pleasure car off the roads, and those plutocrats who rejoice in the Rolls-Royce will betake themselves to the air. What the effect of this upon mortality statistics will be is a question for prophets of the school of Mr. H. G. Wells.

#### AGRICULTURE AND HELMINTHOLOGY.

THE duties of the Ministry of Agriculture are many and various, but they all have to do with the food of man, its quantity and quality, but in particular perhaps the former, which is apt to be diminished by a vast number of parasites, animal and vegetable, including bacteria, fungi, protozoa, and worms. In the study of animal pathology the Ministry already assists in the maintenance of the department in Cambridge now under the direction of Professor J. B. Buxton. For the study of the preventive side—that is to say, for the observation of infestations of animals and plants—the Ministry has recently enabled the London School of Hygiene and Tropical Medicine to establish a small experimental field station near St. Albans, which has been appropriately placed under the directorship of Professor R. T. Leiper, F.R.S. It is not yet in full working order, but already certain researches are under way. In a new field of experimentation like this it is probable, of course, that not a few results, at the beginning at any rate, will be negative. The field station consists of a small farmhouse and outbuildings and thirty-three acres of land pleasantly situated, partly surrounded by woods, and bounded on two sides by the Herts County Council Agricultural Institute. The barns have been converted into laboratories for the accommodation of at least five research workers, for in addition to the director there must be assistants dealing with helminthology, protozoology, bacteriology, and fungi. The stabling is at present used mainly for goats, and other buildings have been converted into habitations for cats and rabbits, or for housing incubators for poultry and pheasants. Attached to the buildings are kennels and runs for dogs, and pens used at present chiefly for the breeding of guinea-pigs. The pasture is being used for experiments on the roundworms and tapeworms of lambs, and the arable land for the investigation of the attacks of eelworms on various roots and crops. Many interesting results have already been obtained. Thus lamb tapeworm disease was supposed to be communicated through the mother's milk. But here may be seen a sheep brought up by the ewe and showing no sign of tapeworm, while its brother and cousins, brought up on cow's milk—with a curious stunting of growth as a result—and then pastured on infected grass, are passing innumerable tapeworm segments. So far the intermediary host of this tapeworm has eluded research. To eelworms has been attributed one of the forms of potato disease. But it is possible that the presence of the cysts of the worm on the rootlets which attracts the attention of the cultivator is rather a coincidence or a sequel than the actual cause of the disease. At all events; potato plants infested with eelworm may show very little difference in growth or produce from those not so infested. These eelworms are of topical interest because of the development of the beet-sugar industry in this country. Abroad the beet is very liable to infestation; the crops in this country have been grown from seed, so that the variety infesting beet has not been imported, though it is, of course, not at all certain that it may not find its way here. Many kinds of plants in this country are infested with eelworms, and it appears that the eelworm of one vegetable, such as the potato, does

not, although morphologically identical, attack a different vegetable, such as the beet. This opens up great possibilities for the study of host varieties, and researches of this kind, directed by an able director, cannot fail to be of enormous value to the cultivator.

#### THE PREVENTION AND EARLY TREATMENT OF MEASLES.

FROM much experience of naval cadets and boys at D. mouth and in training establishments and ships, Surgeon Commander B. Pickering Pick<sup>1</sup> brings out some points showing the benefit to be obtained by the patients and preventing the spread of the infection as a result of recognition and isolation of the first case or cases: a collection of young non-immune boys. This process has also enabled him to make some observations on clinical features at a stage of the disease which does not commonly come under notice. Early rest in bed in even temperature for four days before the appearance of the rash was found to be definitely valuable as a prophylactic of complications. In a recent epidemic involving 110 cadets this plan was followed by complete freedom from pulmonary affections, although there was a pharyngeal and tracheal cough. Isolation of the first and of the contacts at the earliest possible moment shown to be capable of obviating an epidemic; an important factor is the close inspection of the records of the temperature in the potential cases, a morning rise after a normal temperature on the previous evening being suggestive of infection. In quite a large number of cases there was a lenticular eruption of widely scattered spots, rose-tinted to brown in colour, on the trunk twenty-four to forty-eight hours before the true rash came out. It may be noted that these prodromal rashes, which are variable in nature and transient in duration, have been estimated to occur in 50 per cent. of the cases. Commander Pickering's experience showed that the longer the pre-eruptive stage the more severe was the exanthem, but that the rash was sometimes scanty and transient; he thinks it probable that it may be absent. Little reliance was placed on Koplik spots, which did not assist much in diagnosis, as they were not frequent in one epidemic, thus differing from the usual estimate of 90 per cent. or more. The potential cases which actually developed did so with remarkable uniformity on the eleventh day from exposure to infection. As a last practical point attention may be directed to the author's conclusion that the period of treatment usually recommended is not sufficiently long, and that twelve days' rest in bed, including three days after temperature is normal, is followed by rapid convalescence.

#### THE FUNCTION OF THE SPLEEN.

SIXTY or seventy years ago students were taught that the spleen acted as a reservoir for the blood, which was emptied from it into the general circulation when the body required it. This theory was for long under a cloud, but Barcroft and others have recently shown that the spleen does act as a reservoir, and empties itself when the body requires more haemoglobin. Then the reservoir is filled again. The only source from which it can be filled is from the blood supplied to it by the general circulation. The question has been raised whether this blood differs from that of the general circulation, or whether it is detained without selection. Answers have been sought by two workers at the Physiological Laboratory, Cambridge—Orlovatz, Rockefeller Fellow from the University of Sofia, and E. W. H. Cruickshank.<sup>2</sup> The particular quality chosen by the former was the resistance of the blood of the spleen

<sup>1</sup> Pick, B. P., *Journ. Roy. Nav. Med. Serv.*, 1925, xii, 201-206.  
<sup>2</sup> *Journ. Physiol.*, vol. lxi, pp. 435 and 455.

haemolysing agents. Previous work had shown that the spleen has an effect on the red blood corpuscles. After splenectomy the red cells of the general circulation are more resistant to hypotonic solutions. Brinkman, investigating the resistance curves of normal blood, concluded that in circulating blood there are three groups of red cells with different resistances to hypotonic solution. First, a most resistant group of about 10 per cent.; secondly, a middle group of about 80 per cent.; and thirdly, a group of very little resistance, the cells being disintegrated at a very low degree of hypotonicity. He called these three groups young, average grown, and old cells. The blood of the spleen, when examined in a similar way, differs. The red cells of the spleen are less resistant than the red cells of the general circulation. They cannot be divided into the same groups. The average group is present, but less resistant. The other groups are not marked off from the middle group, and the type of old or least resistant cell does not seem to be present in the blood of the spleen. It is therefore concluded that the blood of the spleen is a selected blood, and that it is less resistant to hypotonic solutions. When haemolysed by saponins the blood of the spleen is more resistant than the cells of the general circulation. From other observations it is inferred that the lessened resistance to hypertonicity and the greater resistance to saponins are due to a smaller content of phosphoric acid. The red corpuscles of the spleen would therefore contain less phosphoric acid than the cells of the general circulation. That these differences do not arise owing to residence in the spleen was shown by emptying the spleen and then immediately collecting the blood as it was allowed to re-enter the organ. This blood was found to contain corpuscles whose resistance was the same as that of corpuscles obtained from the spleen before it was emptied. Cruickshank found that the spleen, when made to contract by electrical stimulation of the splanchnic nerves, will expel in the cat an amount of blood that represents 2.5 to 5.6 per cent. of the total blood volume of the animal. This blood is more concentrated and therefore richer in haemoglobin, to the extent that 8 c.cm. of splenic blood is equivalent to 9.5 c.cm. of normal blood. So far as these investigations go the functions of storing and concentrating blood seem to be peculiar to the spleen.

#### CONTAGIOUS BOVINE ABORTION AND UNDULANT FEVER.

ALL medical men are now familiar with the recent work—mainly French and American—which has shown the existence of a relation, apparently very close, between contagious abortion of cows and pigs and undulant fever of goats and man. It is now generally believed that the same organism is responsible for both diseases, but that the caprine strain is normally pathogenic for man while the bovine strain is harmless, only becoming pathogenic in exceptional circumstances. Bevan<sup>1</sup> reported outbreaks of what appeared to be human undulant fever in Rhodesia, and believed that he could definitely exclude goats or sheep as the source of infection. Contagious abortion, however, existed in cattle, and he considered that this was the origin of the disease in man. More recently Moore and Carpenter<sup>2</sup> have reviewed our present knowledge of the position. As early as 1915 Larson and Sedgwick tested by complement fixation the serum of women who had aborted, and found that a larger number reacted when the contagious abortion organism was used as antigen than when the usual Wassermann test was applied. Similarly, children from bovine abortion districts often showed the presence in their blood of antibodies of the *Bacillus abortus*, while those from districts free from that organism did not give a positive reaction. This has been the experience of sub-

sequent workers. The number of recorded cases of undulant fever in patients who have had no opportunity of contracting the disease from goats is gradually increasing. Kennedy in 1914, for example, found two cases in England in people who had never left the country. Keefer in 1924 reported a case in America in which the organism was actually isolated and in which the clinical picture was that of an undulant fever. Other cases have been recorded from many parts of the world in which the source appeared to be either raw cow's milk or else actual contact with infected bovine placental or other material. Moore and Carpenter report six new cases from America. The first was diagnosed originally as typhoid fever, later as miliary tuberculosis, and then as malaria; but blood cultures on six occasions revealed the *B. abortus*. The patient presented the typical syndrome of undulant fever. The microbes isolated from several other cases have produced typical bovine abortion in heifers. The source of the infection in this series appeared to be cow's milk. After tuberculosis, contagious abortion is the most important and widespread disease of dairy cattle in England. The organism is frequently excreted in the milk, and undoubtedly many people ingest it daily. English people, moreover, have no natural immunity to undulant fever, though there is no general infection. The results quoted above, however, indicate that its presence cannot be ignored as a source of some of the low-grade fevers of unrecognized etiology found in this country. The *B. abortus* has another importance to those engaged in public health work. Injections of this bacillus in milk into guinea-pigs produce a pathological picture which is very similar in many cases to that produced by the tubercle bacillus, and unless the lesions are examined microscopically for the presence of acid-fast organisms the milk may be unjustly condemned as tuberculous.

#### KITCHENER MEMORIAL MEDICAL SCHOOL AT KHARTUM.

THE buildings of the Kitchener School of Medicine, Khartum, were completed by the end of 1923, and the school was formally opened by the late Major-General Sir Leo Stack on February 29th of the following year, this being his last public act in the Sudan. The inaugural address which he delivered on this occasion is published in the first report of the medical school, which has now been issued. A general outline of the proposed curriculum was published by Dr. O. F. H. Atkey, director of the medical department of the Sudan, in our columns on September 29th, 1923 (p. 581), and the first report of the school, which covers the years 1924-25, shows that good progress is being made in every way. The building stands on two and a half acres of land, and contains laboratories for teaching chemistry, physics, biology, anatomy, physiology, and pathology, with a lecture room and a library. Clinical instruction is given at the Khartum Civil Hospital, where a new out-patient department has recently been completed. Medical research laboratories are shortly to be built in the hospital enclosure immediately opposite the school buildings; increased facilities will thus be afforded for tuition in pathology, including bacteriology, protozoology, and parasitology, while opportunities will be afforded for post-graduate research. An additional school hostel is proposed, in order that the increased number of students expected in 1927 may be accommodated. These students will be drawn for the most part from the final year of the Gordon College. At the opening of the school ten students were admitted, and in 1925 an additional eight were received. A four-year course is the rule; the first year is devoted to chemistry, physics, and biology, the second to anatomy and physiology, the third to medicine, surgery, pathology, and pharmacy,

<sup>1</sup> BRITISH MEDICAL JOURNAL, March 21st, 1925, p. 554.

<sup>2</sup> Cornell Vet., 1926, xvi, p. 147.

while the fourth includes the last four subjects with the addition of gynaecology, forensic medicine, and public health. The first objective of the school is to supply a simplified medical education for young Sudanese, who will work subsequently under British doctors at the larger hospitals, take charge, under some supervision, of smaller hospitals and dispensaries, and engage in campaigns against endemic diseases. Later on, when the present urgent need for doctors has been met, it is proposed to raise the standard of training by increasing the length of the curriculum to five years, thus bringing it into line with that of European medical schools. Post-graduate classes will also be established for students who have previously graduated. It is hoped to supply an average of six doctors each year, beginning in January, 1928. The anticipated expenditure of the school for the years 1925, 1926, and 1927 is approximately £3,000, £5,000, and £6,000 respectively. An annual income of £3,019 is provided by the interest on the endowment fund, together with an annual grant from the Lord Kitchener National Memorial Fund; it will be necessary, therefore, to supplement the income from other sources.

#### PROTECTION OF SEAMEN AGAINST VENEREAL DISEASE.

We published recently (July 31st, p. 205) a report of an international conference in Norway to consider an international scheme put forward by the Norwegian Red Cross Society for the promotion of the health and welfare of the sailor. One of the resolutions of the conference was to the effect that the League of Red Cross Societies should invite the International Health Office, the Health Organization of the League of Nations, and other international organizations, to appoint a standing committee on the welfare of seamen, which should provide, in particular, for medical treatment and recreational facilities at ports. The matter has been for some time under the consideration of the International Labour Office, which has issued recently, as one of its series of studies and reports, a history of the movement, initiated some years ago, for the protection of the health of seamen against venereal diseases.<sup>1</sup> While venereal diseases were being actively attacked amongst the civil and military populations during and after the war, nothing had been done, either nationally or internationally, to combat them in the mercantile marine, notwithstanding the obvious danger of disease being introduced into the country through the ports. We understand that this was strongly brought to notice by the chairman of the Services Committee of the National Council for Combating Venereal Disease some seven years ago, and, although the document under review does not record this fact, the opportunity is taken of referring to it here, as the credit of a movement, which has developed into an international convention and is bound to have a beneficial influence on the mercantile marine of all nations, should be granted to those who worked with the National Council for Combating Venereal Disease in the early years after the armistice. The movement passed from national to international spheres of action at the International Labour Conference held at Geneva in 1920 specially to consider maritime questions. The present report relates how it developed from that time, until eventually an agreement, drafted originally in 1921 by the Office international d'hygiène publique in Paris, providing for the maintenance of venereal treatment centres at the chief river and sea ports for merchant seamen and watermen of all nationalities, and for enabling continuous treatment to be carried out at sea and on

shore, was signed in April last by several States as an international convention. It is unfortunate that certain countries—notably Germany, Japan, Spain, and the United States, as well as Australia and South Africa—have refused to adhere to it, so that there are still several gaps to fill in the benefits afforded by it. The movement, however, is still in its infancy internationally, and the International Labour Office has done good service in issuing a report on the subject at the present time. Co-ordination of and uniformity in measures of prevention and treatment in different countries are needed, and the information now published in our columns and in the report of the International Labour Office should go far towards the attainment of an object which all civilized nations must have equally at heart.

#### TUBERCULOSIS IN NOVA SCOTIA.

THE Department of Public Health of the Province of Nova Scotia has issued a statistical study of tuberculosis in the province during the years 1909 to 1925. It is noted that there has been a marked diminution in the number of deaths and a lowering of the rate. The improvement is limited almost wholly to the pulmonary form of the disease, and is most noticeable in the age group 20 to 49. From 0 to 5 years there is also a very marked drop in pulmonary tuberculosis, but from 5 to 14 very little change. The improvement in infants and young children is attributed to improved conditions in the home and to education in preventive measures. In the first half of the period the rural deaths were at a higher rate than the urban. In the second half of the period the position is reversed. In Nova Scotia, unlike England, the female rate is higher than the male. For these and other observations made the report offers various explanations. We deprecate, however, the implication conveyed in the statement: "The improvement shown has been limited largely to certain age groups, notably the sanatorium age groups." With so elusive a disease as tuberculosis it is perhaps a pity in giving statistics to label particular age groups in this manner. It is surely sufficient to establish the fact that mortality has been reduced at certain ages, to note then that many patients at those ages undergo sanatorium treatment, and subsequently to investigate any other possible factors in tuberculosis mortality at those ages, for the purpose of finding out if it is possible to correlate these factors. Further investigation seems to be needed to justify the inference drawn in the report that "for at least some of the improvement observable in connexion with the pulmonary disease credit ought to be given to the treatment facilities of the province."

#### HEART DISEASE IN NEW YORK.

We have received from the director of the New York Tuberculosis and Health Association a report from its Heart Committee (formerly called the New York Heart Association) of an investigation undertaken to explore the ground before attempting to deal with the prevention of heart disease on a national basis. The report is founded on a study of 1,000 heart cases, most of them attending the Bellevue Cardiac Clinic for Adults. The authors carefully guard against their conclusions on 1,000 cases being taken as true of 10,000 or 100,000. While pointing out the necessity of further detailed study if we are to proceed with intelligence in preventing heart diseases, they present certain conclusions, of which the following is a summary. The mortality from heart disease was about equal for the sexes in the higher age groups. Rheumatic heart disease seemed to be as common among males as among females. But in syphilitic heart disease the ratio of males to females was about 7 or 8 to 1, and arterio-sclerotic heart disease appeared to be much more common among males

<sup>1</sup> *Protection of the Health of Seamen against Venereal Disease*. International Labour Office. Studies and Reports, Series P (Seamen), No. 2. Geneva, 1926. London: F. S. King and Son, Ltd. (9½ x 6 in., pp. 72, Price 1s.)

han females. The reasons for this discrepancy between the sexes have not yet been ascertained. In about three-fourths of the cases of rheumatic heart disease, rheumatic fever, either alone or in combination with other infections, was an etiological factor; tonsillitis in one-fourth; chorea a little more than one-tenth; and "growing" or joint pains in about one-twentieth. With the exception of chorea, which occurred twice as often among females as males, the relative frequency of these infections was about equal for the two sexes. Rheumatic heart disease was rare after 50 years of age; from 90 to 95 per cent. of the cases occurred before the age of 50 years, and more than half of these before the age of 30. About 50 per cent. of the syphilitic cases occurred before the age of 50, and 50 per cent. after this age; the disease appeared to be rare before the age of 40 and after the age of 60. From 80 to 95 per cent. of the cases of arterio-sclerotic heart disease occurred after 50 years of age. Two-thirds of the cases of unknown etiology presented lesions typical of rheumatic heart disease, and occurred before the age of 50. The available mortality statistics for organic heart disease are considered to be inadequate to justify any attempt to study the age incidence and duration of the disease, because they are based on deaths recorded in accordance with the International List of Causes of Death, which is not so classified as to make it possible to distinguish between the infectious and degenerative varieties of the disease. It should be added that in this investigation the proportion of cases in children was slightly lowered by the method of investigation used.

#### UNDESIRABLE IMMIGRANTS IN MARSEILLES HOSPITALS.

A few months ago (April 3rd, p. 631) our French correspondent called attention to some recent statements made by M. Weil to the Académie de Médecine, and M. Marie to the Medical Society of Paris, as to the large proportion of foreigners in the hospitals of Paris, and M. Berthoumeau raised the same question in relation to the great convalescent home for patients discharged from the hospitals of the capital. He found that the percentage of inmates born outside French territory had risen from 5.6 in 1914 to 14.6 in 1925. He added that the number of British subjects in Paris hospitals is negligible. A similar question has now been raised before the Académie de Médecine by Dr. Léon Imbert, who described the effect of post-war immigration of foreigners of the pauper class on the hospitals in Marseilles. After each catastrophe, he said, such as the disaster to Wrangel's army, the burning of Smyrna, the expulsions from Constantinople, a fresh influx of undesirables has occurred, with the result that 25 or 30 per cent. of patients in Marseilles hospitals are foreigners, and even at Lyons the proportion has risen in three years from 4.5 to 7.3 per cent. Very often admission has to be refused to a French patient. Dr. Imbert does not object to Italian immigrants, whose assimilation into the Marseilles population is rapid; though he hints that Italy, with her lively consciousness of her personality and the role she has to play in the world, might establish a hospital of her own in Marseilles, or, better still, subsidize existing hospitals. But he would like discussion raised on the motley crowd of Syrians, Armenians, and so on, who flood the hospitals. It is only too evident that the Governments of the native countries of these people have washed their hands of them, although they have embarked for Marseilles at the orders of those Governments. In the discussion which followed Dr. Imbert's paper, Dr. Jeanselme enumerated the sixteen different nationalities of 27 out of the 211 patients treated in the venereal disease clinic of the St. Louis Hospital. He stated also that 11 out of 42 in-patients were foreigners. Dr. Léon Bernard

suggested that as many of Dr. Jeanselme's patients had probably contracted syphilis in Paris, the right to complain was perhaps on their side. Apparently an attempt is to be made to deal with the situation by appointing a commissioner of immigration and naturalization; it is suggested also that an international understanding is necessary.

#### AVIAN TUBERCULOSIS.

Recent years have shown an increasing tendency to consider the problems of human and bovine tuberculosis as merely aspects of the same great problem; but avian tuberculosis has not received the same amount of attention, though cases due to this strain have been reported in practically all the domestic mammals and in man. To the rabbit, and to the pig also, avian is almost as pathogenic as is bovine tuberculosis, but to other mammals it is less infective than the mammalian strains. Tuberculosis in birds is exceedingly common throughout the world, and practically all species may be infected. The barnyard fowl is the chief reservoir, but the disease is often conveyed by pigeons and other smaller and more mobile birds. Parrots have a peculiar susceptibility to all three strains, and may suffer from human, bovine, or avian tuberculosis. Apart from the great economic loss to poultry farmers, the problem of avian tuberculosis has a twofold interest. That it is a very common source of infection in pigs—producing, however, a more benign disease than does the bovine virus—has been known since the time of the Royal Commission on Tuberculosis, but from the results of a recent inquiry in Nebraska, U.S.A., it appears that nearly 90 per cent. of the cases of tuberculosis in pigs are due to the avian bacillus. Recent studies in Denmark of contagious abortion have shown also that the avian bacillus may cause tuberculous metritis in cattle, leading to placental detachment and subsequent abortion, and that this strain has a certain predilection for the pregnant uterus. So far the prevalence of avian tuberculosis has had only an economic importance, but the influence of poultry diseases on human medicine has been so considerable that we cannot afford to neglect this aspect of the general disease. Pasteur began protective vaccination with chicken cholera; Ross did his preliminary work on the transmission of malaria with the avian disease; and more recently Gye has advanced his theory of the causation of cancer from a study of Rous's infective sarcoma of fowls. These three examples serve to show how unwise it would be to neglect the study of diseases of birds which in themselves may not seem to cause danger to human health.

THE University of Sydney is about to appoint a professor of psychiatry, who will be required to give both undergraduate and post-graduate instruction. He will be expected to engage in research, but to be interested in clinical rather than in pathological work. He will have access to all mental hospitals, and will have the assistance of the departmental pathological laboratory. He will be required to act as honorary physician in connexion with the out-patient department at the Royal Prince Alfred Hospital, as visiting officer to Broughton Hall Hospital (150 beds) for uncertified mental patients, and to take charge of the patients in it. He may engage in consulting practice, but approximately half his time must be devoted to University and State duties. The salary is £1,100 a year; he will be appointed for seven years, but may be reappointed. A notice of the vacancy will be found in our advertisement columns, and full particulars can be obtained from the Registrar of the University, or from the Agent-General for New South Wales, Australia House, Strand, London, W.C.2.

## England and Wales.

### NOTIFICATION OF PUERPERAL FEVER OR PYREXIA, AND OF OPHTHALMIA NEONATORUM.

THE Minister of Health has issued amended regulations, to come into force on October 1st, relating to the notification of puerperal fever and puerperal pyrexia, and of ophthalmia neonatorum.

In a circular to the local authorities the Ministry states that experience has shown the incompleteness of the notifications of puerperal fever, and that this has resulted, not only in inaccurate and misleading statistics, but in hampering the effective prevention and treatment. The term "puerperal fever" is not precisely defined, and frequently a genuine doubt exists as to the correct diagnosis, while the implication of some slur on the patient or attendant may act as a deterrent against notification in doubtful cases. It is intended ultimately to replace the term "puerperal fever" by "puerperal pyrexia," but this cannot be done on the notifications without amending legislation. For the present, therefore, two forms of notification are to be used, one as at present, though with some alteration in its terms, embodying the words "puerperal fever," and the other "puerperal pyrexia." Puerperal pyrexia is defined as

"any febrile condition (other than a condition which is required to be notified as puerperal fever) occurring in a woman within 21 days after childbirth or miscarriage in which a temperature of 100.4 deg. F. (38 C.) or more has been sustained during a period of 24 hours or has recurred during that period."

Medical practitioners, therefore, will now be required to notify, not only puerperal fever as heretofore, but all cases of pyrexia during the puerperium, irrespective of the cause to which the fever may be attributed. It is recognized that this requirement will lead to a great increase in the number of notifications, and that many cases reported will be relatively trivial, but the importance of securing adequate treatment in the early stage of infection is held to outweigh these objections. The Ministry believes, on the basis of reports from various maternity institutions, that pyrexia during the puerperium is not infrequently looked upon as a comparatively unimportant incident, and that proper precautions to prevent the spread of infection are at times neglected, with disastrous results. The new forms of notification declare that, in the opinion of the notifier, the patient is suffering from puerperal fever (or, in the second form, puerperal pyrexia), with the date of onset of the disease and of the birth of the child, and continue:

I desire

- (i) to have a second opinion on the case;
- (ii) to have a bacteriological examination of (a) lochia, (b) blood;
- (iii) that the patient be admitted to hospital;
- (iv) that trained nurses be provided;

or

Facilities are available for all necessary treatment.  
(The inappropriate words are to be struck out.)

In the notification of puerperal fever a special form for the metropolis has still to be used, providing for the information required under the Public Health (London) Act, 1891, as to the origin of the case and whether it occurred in private or institutional practice. The covering circular adds that the facilities for assistance in diagnosis and treatment can most readily be provided by the local authority which administers schemes under the Maternity and Child Welfare Act, 1918, and such authorities and their medical officers are urged to do all that is possible to meet the requests of practitioners for special assistance. Practitioners so requesting may be required to supply information as to any conditions prior to labour which might have been factors in producing pyrexia, the names of all persons who made internal examinations, particulars of the clinical course of labour, the history subsequent to delivery, and any cases of specific fever, erysipelas, or puerperal pyrexia visited recently by the doctor or other attendant.

The amended regulations with regard to ophthalmia neonatorum place the duty of notifying such cases solely upon the medical practitioner in attendance. Under the

existing regulations an obligation rests upon a cert midwife to notify any case in which she has reasonable grounds for supposing the existence of this condition unless the case has already been notified by the practitioner. This dual responsibility has in some cases resulted in complete failure to notify; moreover, as midwives are required to call in medical help for any inflammation or discharge from the eyes, however slight, and to give notice to the local supervising authority, the requirement to notify ophthalmia neonatorum tends to confuse them to their duty. It is to be made clear to midwives that they will still be required to summon medical assistance in cases of inflammation or discharge and to advise the local supervising authorities.

The Ministry is of opinion that, following the regulations or notifications, the proper authority to carry out necessary measures of visiting and home nursing, or provide hospital treatment where required, would be one entrusted with the scheme for maternity and child welfare. In notified cases of ophthalmia neonatorum the medical officer of the maternity and child welfare authority should personally ascertain from the practitioner whether nursing or other assistance is needed. It is added, as parents sometimes object to the recovery from the patient by the supervising authority of the fee paid to the practitioner called in by the midwife, the authorities may consider the advisability of refraining from exercising their power of recovery in this class of case in view of the importance of promptitude in seeking medical aid.

### KING EDWARD'S HOSPITAL FUND FOR LONDON.

Three gratifying features of modern hospital administration are indicated in a statistical report on the income and expenditure of London hospitals for the year 1925 just issued by King Edward's Hospital Fund for London. These are the great expansion of work, a relative reduction in its cost, and an increase in income. The report deals with 118 hospitals, containing 13,700 beds. During the year under review 240 additional beds became available and the average number occupied increased by 500 over the corresponding figure for the previous year, thus raising the percentage of occupied beds from 81.4 in 1924 to 86.2 in 1925, and approaching what used to be considered a normal percentage of 86. The increased celerity in medical treatment is shown by the fact that, whereas the number of patients per occupied bed was 14.3 in 1913, it was 16.2 in 1923, 16.2 in 1924, and 16.4 in 1925. The average duration of stay for each patient has fallen from 25.5 days in 1913 to 23 in 1923, to 22.6 in 1924, and to 22.3 in 1925. The number of new out-patients, which showed an increase in 1923 of 37,000 over those of 1913, and a further addition of 56,000 in 1924, rose still higher in 1925, when there was an increase of 89,000 over the total for 1924, and of 182,000 over that for 1913. Out-patient attendances increased 349,000 over those of 1924, and by 2,006,000 over 1913. The average attendances of each out-patient were 4.4 each of the three years 1923-25, as compared with 3.5 in 1913. The total out-patient attendances in 1925 were 7,026,000, and the total number of new in-patients 187,000.

The combined income of the 118 hospitals amounted to £3,029,000, as compared with £2,918,000 in the previous year; the increase was wholly in ordinary income, legacies and other sources of extraordinary income showing a decrease of £115,000, as compared with 1924. Subscriptions and donations increased by £98,000, payments by patients by £74,000, and receipts from public authorities by £18,000. It is interesting to note that, whereas in 1913 payments by patients were £105,000, as compared with £648,000 in the year under review, receipts from public authorities amounted to £247,000, as compared with £2,000 in 1913. Grants from public authorities now amount to 30.1 per cent. of the total Fund income, as compared with 8.2 in 1913; payments by patients represent 21.4 per cent. of the total income. The income of the Fund as a whole is more than double that of 1913, and the great increase comes under the heading of "Receipts for services rendered by the hospital."

to deal with their past deficits and to maintain a continually increasing number of beds. The number of hospitals whose annual income failed to meet their expenditure has fallen from 77 in 1920 to 49 in 1925. In addition to annual income the 118 hospitals have raised £167,000 for endowment, and £691,000 for building and equipment. The difficulties of these hospitals in the years immediately following the war are attributed to increase of expenditure and not to decrease of income. After having risen from £1,204,000 in 1913 to £2,808,000 in 1920, expenditure began to decrease, and fell to £2,594,000 in 1922, when there was some curtailment of work. Since then there has been an increase in work, and expenditure has increased; it reached £2,756,000 in 1924 and £2,906,000 in 1925, when there was a marked expansion in both in-patient and out-patient work; while the increasing expenditure in 1925 over 1920 was 3.5 per cent., the increase over 1920 in work was 8 per cent. in the in-patient department and 10 per cent. in the out-patient department. The increase in the volume of work was thus accompanied by a relatively lower expenditure in spite of the cost of the additional medical and surgical benefits provided by hospitals as the result of advances in medical and surgical practice since 1920.

The report contains sections of the nature of appendices giving details of the work and accommodation in the 118 hospitals, analyses of their income and ordinary expenditure, particulars of the more controllable items of expenditure, and group comparisons of the cost of working in the cases of the larger general hospitals, with and without medical schools; smaller general hospitals; cottage hospitals; hospitals for women; children's hospitals; ophthalmic hospitals; and hospitals for epilepsy and paralysis. It is announced that a fresh series of reports will begin next year when the new edition of the *Revised Uniform System of Hospital Accounts* will be in operation.

#### TREATMENT OF TUBERCULOSIS IN LANCASHIRE.

Sir Henry F. Hibbert, Bt., chairman of the Lancashire County Council, opened the Rufford Pulmonary Hospital, near Ormskirk, on August 5th. This new hospital has been constructed by adapting the buildings composing Rufford Hall, which was purchased by the Lancashire County Council in 1920; it provides fifty beds, and will receive patients more especially from West Lancashire. The total cost of the purchase and equipment was £31,844, and grants had been received from the Lancashire Insurance Committee and the Ministry of Health. Sir Henry Hibbert stated that the average cost per bed would be about half that in other hospitals. He added that the deaths from pulmonary tuberculosis in Lancashire had fallen from 107 per 100,000 in 1918 to 67 in 1925, and that the death rate in the county was less than the average for England and Wales. Lancashire had spent £170,000 on the treatment of tuberculosis; there were now fourteen dispensaries in operation, and the total hospital accommodation in the county had increased from 144 in 1913 to 860.

#### RURAL COMMUNITY COUNCILS.

We have received the report of the Kent Rural Community Council for 1925-26. The council was established two and a half years ago as an independent non-official body of representatives of many organizations—official and voluntary—which are concerned in the welfare of the countryside. Apparently fourteen counties in England and Scotland have rural community councils, linked together through the National Council of Social Service. The council in Kent has assisted in organizing such movements as the County Playing Fields Association and the British Empire Cancer Campaign; it has convened conferences on such subjects as village organization, agricultural training and apprenticeship, the welfare of hop-pickers, and the development of drama in villages; it has given concerts in villages, country towns, and at schools; and it is now extending its activities in the direction of juvenile welfare and public health. By the promotion of juvenile welfare committees, the council hopes to obtain the discussion of social developments from the young people's standpoint, and to foster their interest in the Kent Education Committee's schemes for juvenile welfare and the County

Council's proposals for the treatment of crippled children. Through a standing committee on public health, the council proposes to spread in the villages a better knowledge of public health administration. It is encouraging the formation of public health committees by village community councils. The experiment sounds interesting, though it has plainly many dangers. An enthusiastic public health reformer in some of our villages would not only find much to occupy his mind; he would possibly occupy his body in defending himself against the irate perpetrators of private and public nuisances.

#### MORISON MEMORIAL AT HARTLEPOOLS HOSPITAL.

On August 1st Princess Mary opened the new wing of the Hartlepool Hospital as a memorial to the late Dr. A. E. Morison, who was connected with the institution for twenty-three years. The new wing is a three-story building, and contains two wards and a children's ward, with accommodation for the whole of the nursing staff of the hospital. The cost of erection was about £10,000, towards which the joint committee of the British Red Cross and the Order of St. John of Jerusalem has contributed £5,000, and Messrs. J. Nimmo and Sons provided the children's ward. The hospital was originally built in 1857 and on two previous occasions additions have been made. By this new extension its accommodation will be raised from fifty to eighty-six beds.

#### NEW HOSPITAL AT EBBW VALE.

The new hospital of the Ebbw Vale and District Voluntary Fund was opened by Dr. Rocyn Jones on August 11th. The fund was started in 1922, and the building contains three wards with accommodation for ten beds, an x-ray room, and staff quarters. Sir Ewen Maclean, who attended the opening ceremony, recalled his visit to Ebbw Vale fifteen years previously, when they had been struggling to establish the "free choice of doctor," a matter of the greatest importance both to patients and to the medical profession. The health scheme formulated by the Welsh Consultative Council had been temporarily held up by the difficult economic conditions. Sir Ewen Maclean believed, however, that before long it would be possible to put the recommendations into operation and so benefit the many crowded districts of Wales. As soon as the new scheme became effective all available hospital accommodation would be required, and the best consultative and executive skill would be provided in all localities. The council intended to establish a consultative centre in Ebbw Vale, and this would result in the statistics of the district being studied and plans made for the improvement of the public health of the community. Sir Ewen Maclean added that he believed that in his own lifetime they would see the materialization of a great scheme which would place Wales in the forefront in health matters in Great Britain, and perhaps in the whole world.

## Scotland.

#### SCOTTISH RESEARCH WORK IN ANIMAL DISEASES.

THE annual meeting of the Animal Diseases Research Association was held at Moredun Institute, Gilmerton, near Edinburgh, on August 12th. The report for the year to March 31st last stated that research work was being carried on in laboratories rented from the Glasgow Veterinary College, pending completion of the new institute at Gilmerton and of laboratories in the Royal (Dick) Veterinary College. The research staff concentrated upon braxy, lamb dysentery, louping-ill, scrapie in sheep, and grass disease in horses. Lack of accommodation for the maintenance of farm animals at the laboratory at present available had seriously handicapped the work, but would be ample in the new institute, the building and equipment of which had already cost nearly £13,000. The Board of Agriculture continued to pay, as in previous years, two-thirds of the maintenance expenditure, and the association had to raise one-third from private sources. Part of this had been contributed by various county councils and agricultural associations.

## UNVACCINATED CHILDREN IN THE WEST OF SCOTLAND.

In the report on the health and sanitation of Dumbartonshire for 1925, Dr. T. L. Thomson, medical officer of health, draws attention to the large percentage of unvaccinated children. It was highest in the Vale of Leven, where it amounted to 44.5 per cent. Attention is drawn in the report to the danger which would attend the accidental introduction of a case of small-pox into this community, for it would almost certainly produce an epidemic of great magnitude. Attention is also drawn to the fact that there is not yet any accommodation for the treatment of small-pox in this county.

## DIAGNOSIS OF SMALL-POX.

A recent bulletin of the public health department of Glasgow refers to the case of a patient who had been removed from a liner outward bound from Glasgow to Canada, which left on June 25th. The patient had, before his departure, resided in the central district of Glasgow. He had sickened on a liner on July 2nd, and had been removed from the ship at a quarantine station. It is obvious from the dates that if he suffered from small-pox he must have been infected in Glasgow. There had been four cases of chicken-pox in the patient's home, and there had been a small school epidemic of the disease in the district where he had resided. Two of the members of the patient's family suffering from chicken-pox at the time when the patient was infected had been successfully re-vaccinated. From the evidence it is therefore clear that the disease to which the patient had been exposed was chicken-pox. In the meantime examination of the patient's skin showed that its appearance was consistent with the disease from which he suffered having been chicken-pox. The case is interesting as showing the difficulty that exists in diagnosis between cases of chicken-pox and small-pox, and the complications that may ensue should the diagnosis be mistaken.

## Ireland.

CENTENARY OF THE COOMBE LYING-IN HOSPITAL,  
DUBLIN.

The centenary of the Coombe Lying-in Hospital, Dublin, will be celebrated next month by a congress. The governors of the hospital will hold a reception on the evening of Tuesday, September 14th, in the Royal College of Surgeons, where, on the following morning, the congress will be opened by the president, Sir William J. Smyly, M.D. Afterwards a paper on obstetrical teaching in Sweden will be read by Professor E. Möller of Lund, and a discussion will be opened by Professor Couvelaire of Paris, who will be followed by Professor Munro Kerr of Glasgow, Dr. Cassidy of Dublin, Professor Fletcher Shaw of Manchester, and Mr. Conyns Berkeley of London. A film on abdominal hysterectomy will then be shown by Professor Faure of Paris, and papers will be read by Professor Eardley Holland of London, on the unnecessary induction of labour, and by Professor Werner of Vienna, on the treatment of climacteric haemorrhages. In the afternoon a visit will be paid to the Coombe Hospital, and there will be a public meeting in the Royal College of Physicians. In the evening a dinner will be given in the Royal College of Surgeons by Alderman J. Hubbard Clark, chairman of the board of governors of the Coombe Hospital. On Thursday, September 16th, a discussion on "The lower uterine segment Caesarean section operation" will be opened by Professor Munro Kerr, who will be followed by Professor De Lee of Chicago, Professor Möller, Professor Eardley Holland, and Professor Werner. Afterwards some historical notes on two important advances in the practice of obstetrics and gynaecology will be read by Professor Donald of Manchester. "Three obstetrical principles" will be set out by Professor De Lee, and Professor Louise McIlroy will read a paper on some problems in ante-natal diagnosis and prognosis. There will be a polo match between Coombe Hospital and the All-Ireland Polo Club in Phoenix Park in the afternoon, and in the evening a special performance by the Abbey Theatre Company. On Friday, September 17th, Professor Hinselmann of Altona will read a paper on eclampsia, which will be discussed by Professor

Eardley Holland, Dr. J. Hendry of Glasgow, Dr. Hugh Davidson of Edinburgh, and Dr. Gibbon FitzGibbon of Dublin. After this papers will be read by Professor R. V. Johnstone of Edinburgh on the early diagnosis of cancer by Professor Beckwith Whitehouse of Birmingham on the cause of menstrual pain, and by Dr. F. Browne on intra-natal infection in the newly born. In the afternoon there will be a garden party in the Zoological Gardens.

## India.

TREATMENT OF CANCER AT THE RANCHI RADIUM  
INSTITUTE.

We have received from Lieut.-Colonel J. C. Vaughan, I.M.S., superintendent of the Radium Institute at Ranchi an account of the treatment of uterine cancer and some statistical returns of general interest in view of the discussion at the Annual Meeting at Bath last year on the treatment of inoperable cancer of the female pelvic organs (JOURNAL, 1925, vol. ii, p. 827).

He states that the practice has been to give an intracervical application of 100 mg. of radium bromide in a glass capsule of 0.5 mm. section contained in a silver capsule of 0.5 mm. thickness enclosed in a brass capsule of 1 mm. thickness surrounded by a rubber tube of 1 mm. thickness. This is kept *in situ* generally for twenty-two hours, and the application is repeated on the seventh or eighth day and again about ten days later. Fourth and fifth applications have been employed only when there has been an insufficient disappearance of the growth about three weeks after the third application. The first application is generally associated with an external application over the fundus uteri of usually 250 to 300 mg. radium bromide, which is only repeated with the second or third application in cases of extreme growth. This external application is generally kept on for the last fifteen hours of the twenty-two hours of the whole treatment. The whole period of treatment usually lasts from about a month to six weeks, of which the first three weeks cover the period on which three applications have been given. The outside applications consist of radium screened with glass, silver, and brass, as described above, with a distance screen of loofah sponges of cotton-wool of 4 to 5 cm. in thickness. In exceptional cases with very large cervical growth involving the vault of the vagina where the os has been practically occluded with growth the first application is made by either placing the tube in contact with the growth, or burying it in the growth, or inserting it just inside the os and packing the vaginal wall round it. At the second and third applications it has been occasionally possible to make the application an intracervical one, and it is in these cases of very extreme growth that usually a fourth or even a fifth application has been employed. The interval between applications was usually determined by the intensity of the reaction (nausea, vomiting, and general malaise) after the removal of the radium, allowing an interval of at least five days after these symptoms have ceased. There was no variation in dose in cases of cancer of the body of the uterus or of the vaginal wall. In the latter there was always an intracervical as well as an intravaginal arrangement of applicator tubes where there was fixation and involvement of the uterine ligaments. The outside application took the form of many small tubes, usually of 5 to 50 mg. of radium bromide each, spread out over the area between the symphysis pubis, the spot where the fundus was palpable, and the anterior superior spine of the ilium of the affected side, or more often over both these triangles where both sides were affected, and even when bilateral involvement was not absolutely demonstrable by a digital vaginal examination, but when from the patient's general condition it was judged wisest to apply the external radium pack as well as the intracervical application. An application over the sacrum has been often combined with the above. In this way each patient received 2,002 milligram hours of each intracervical application and about 4,500 milligram hours of external application, or 3,551 milligram hours each combined in external and internal applications.

The Ranchi Radium Institute was opened on April 1st, 1922, and from then until December 31st, 1925, it has dealt with 27 cases in 1922, 37 cases in 1923, 57 cases in 1924, and 51 in 1925, making a total of 172. Excluding patients who were not treated, being too advanced for any treatment, those who abandoned treatment, and who died in the first few months after having been seen, Lieut.-Colonel Vaughan has classified the remaining 134 in four groups, from which conclusions as to the value of the treatment can be drawn. Of these cases 21 have not been traced definitely; he believes that some are clinically free from disease, but in the absence of

y definite information he has specified them as not traced. results are as follows :

Of 27 cases treated until the end of 1922, or earlier, 3 patients died after six months, 11 after one year, 4 after one and a half years, and 4 after two and a half years. Of the patients living, only one has survived since 1918, and 2 are in the fourth year. Recurrence appeared in 2 other patients after two and a half years of clinical freedom; after further control treatment they again became clinically free. Two patients were not traced at all; one was known to be living in January, 1923. Of 28 cases treated to the end of 1923, 2 died after six months, 6 after one year, and 3 after one and a half years, 2 after two years, after two and a half years. Four patients are living to-day, 11 have not been traced. Of 42 cases treated to the end of 1924, 6 died after six months, 12 after one year, 4 after one and a half years, 11 are living to-day, and 9 have not been traced. Of 37 cases treated to the end of 1925, one died after six months, after one year, and 4 after one and a half years; of the remaining 26 cases 6 have relapsed already and have been receiving treatment up to last March.

#### THE CONNAUGHT HOSPITAL, POONA.

The new British Station Hospital, to be known as the Connaught Hospital, was opened in Poona on April 14th by the Commander-in-Chief of the Bombay Presidency. The main building consists of ground and first floors, which comprise three sets of wards each capable of accommodating 100 to 120 patients. At one side of this building is a smaller block containing the operating theatre and a theatre for x-ray work. A separate building is provided for diseases of the eye, ear, nose, and throat, and some 200 yards away is a block of infectious wards. In addition to administration buildings, connected by covered passages, bungalows are being erected for the staff. The hospital still requires some internal rearrangement before it can be taken into full use, but when completed it will be the most up-to-date hospital in the residency of Bombay. It has been built on an open site at a high level, and takes its name from the fact that the Duke of Connaught was the originator of the old British Station Hospital, which forms part of the new institution. During the alterations which are necessary the temporary King George's Hospital is being used for medical treatment.

#### DELHI MEDICAL ASSOCIATION.

The heavy mortality among adults and children in India was the subject of an address given recently by the president of the Delhi Medical Association at its annual dinner. It was stated that whereas the death rate in 1923 in London was 12 per 1,000, in New York 13, in the city of Calcutta it was 49.73, in the whole of India 25, and in Calcutta 28.4. The infantile mortality in London was 38, and in New York 181, but in Delhi it was 212, in Calcutta 294, and in Bombay city 624. To combat this high mortality the president urged that the Government should inaugurate a health insurance scheme to provide expert medical advice and treatment, especially in the villages, where more than 90 per cent. of the Indian population lived. The money required for this purpose could, he said, be obtained partly from funds acquired under this scheme, and partly from State grants. Local self-governing bodies should also be stimulated to greater activity in public health work, including educational campaigns. The Delhi Medical Association strongly approved the bill introduced by Dr. Rama Rao in the Council of State, to provide for the constituting of a General Medical Council in India to regulate medical education and keep a register. The president, referring to the scheme of reorganization of the Indian Medical Service, stated that a great injustice would be done to Indian officers if they were to be transferred to military employment to make room for British military officers who, henceforward, would alone treat British civil officers. He paid a high tribute to the Indian Medical Service with its long list of distinguished physicians and surgeons and research workers. He thought the Government should permit the Delhi Medical Association to send an accredited representative to the University of Delhi and the municipal committee. Colonel Franklin, supporting the proposal for a General Medical Council in India, claimed priority in having suggested such a scheme many years ago with Dr. Chandī-Parshad in Indore. He believed that quackery would diminish with the growth of sound

public opinion, and thought the day was not far distant when the civil surgeon would have disappeared and the whole country be included in a panel system.

#### PUBLIC HEALTH IN BENGAL.

Severe criticism of the way in which vital statistics are being kept in Bengal is expressed by Major A. D. Stewart, I.M.S., the director of public health, in the Bengal Public Health Report for the year 1924. Some improvement has occurred in this respect in rural areas, but in the towns, where the registration of births and deaths is compulsory, great laxity still obtains. Out of 115 municipalities offenders were only prosecuted in thirty-seven, and it is emphasized that until greater attention is paid to this matter improvement in the public health must be retarded. Although the cholera mortality in Bengal in 1924 showed a slight increase on that in 1923, the decline in the curve noticeable during the last few years continued. This is attributed in part to the fully trained staffs now employed in anticholera work by the municipalities in disinfecting water supplies, arranging anticholera inoculations, and providing for the education of the people; voluntary agencies have co-operated in this work with very good results. During the first six months of 1925 there was a recrudescence of small-pox in epidemic intensity. The mortality, though high, was not so severe as in the previous epidemic of 1919 to 1920. The number of deaths in the various places appeared to bear a definite relation to the density of the population; the towns were the chief centres of dissemination, and the improved travelling facilities led to increased spread of infection. The general decline in malaria observed since 1921 continued; it was more prevalent and the death rate higher in the rural areas than in the towns. The consumption of quinine throughout the province is as yet not commensurate with the prevalence of the disease. Antimalarial operations in the form of drainage schemes have been put into operation in the Banka Valley, at Meenglas, and in connexion with the rivers Singaran and Bhagirathi. Many voluntary village societies have been formed to spread information about malaria prophylaxis and to provide treatment; grants have been made by the Government in support of this work. The mortality attributed to kala-azar increased during the year, but this may have been due to better registration or more careful diagnosis; enteric fever was less prevalent. Deaths from rabies, pneumonia, and pulmonary tuberculosis were rather more numerous than in 1923, while the incidence and death rate of influenza diminished. The work of the Bengal Public Health Laboratory considerably increased during the year under review; it was found that the quality of the drinking water supplied by the municipalities had improved appreciably; settlement and slow sand filtration appeared to be better processes of purification than rapid filtration, which, when employed, required the assistance of chlorination.

#### AMBULANCE AND HYGIENE TRAINING.

The annual general meeting of the St. John Ambulance Association and the Indian Red Cross Society was held at Simla on June 24th, with the Viceroy in the chair. Field-Marshal Sir William Birdwood, presenting the annual report of the St. John Ambulance Association, emphasized the importance of education in treating accidents and sudden illnesses. Many deaths from drowning and snake-bite were being prevented through the first-aid training now available. Considerable progress had been achieved during 1925, and Indian States, railways, police, educational institutions, prisons, and mines had all joined actively in the work. The course in ambulance training had been taken by 10,340 persons, of whom 1,820 were railway employees. In the All-India ambulance competition at Madras teams consisting of warders, convicts, and boys from the reformatory schools took part, and one convict team came second in the contest for the Jagmāl Raja All-India Labour Ambulance Challenge Shield. The Mackenzie school course in hygiene, sanitation, and first aid, which had proved very successful in the United Provinces, had been recently instituted in other parts of India, and the Indian States had provided instruction

for 1,500 students. Sir B. N. Mitra, reporting on the work of the Indian Red Cross Society, announced that the total membership of the branches had increased from 2,815 in 1924 to 4,200 in 1925. The headquarters organization had carried on an active public health propaganda, and the society was represented at three conferences outside India. During the coming year its representatives would visit the fourth English-speaking conference on child welfare in London and the second Oriental Red Cross Conference at Tokyo in November. The Viceroy, congratulating both organizations, observed how the Government needed and welcomed the assistance of such voluntary bodies in promoting good health, sanitation, and general hygiene throughout the country.

## Correspondence.

### ANTIGENS FOR THERAPEUTIC IMMUNIZATION.

SIR,—In company doubtless with other clinical pathologists in search of the ideal antigen, I welcome Sir Thomas Horder's researches on immunogen antigens (July 31st, p. 177) as a new hope.

At the same time, it does occur to me that there are conceivably vulnerable points in this research work, brilliant though it is. First of all, does it follow that agglutination, complement fixation, and bacteriotropin tests are necessarily criteria of immunity? Admittedly they imply infection, but we know that in gonorrhoea and tubercle, for instance, victory over infection is signalized by a negative complement fixation test, and in syphilis by a series of negative tests. And, again, the healthy human body furnishes its own immunity from the virus, the whole virus, and nothing but the virus, and it seems that in so far as we adhere to nature's methods we shall succeed, and in so far as we deviate from nature we shall fail. Hence I still pin my faith to the autogenous vaccine. The production of a good autogenous vaccine demands very great care in the selection of culture media and the separation of organisms, and also upon a rapid intensive growth of the first subcultures. More failures are probably due to faulty preparation than is commonly believed, and there are some organisms—for instance, certain strains of streptococci—which need very special inducement for rapid growth. May not the autogenous vaccine fall into partial disrepute from insufficient individual attention in an over-worked laboratory? Very easily.

I believe that to deprive an antigen of its toxin is a mistake. Is not the toxin of diphtheria the best immunizing agent we know? Is not diphtheria antitoxin the very crown of immunological success? Can we disregard the toxic element in other instances? I do not think we can afford to do so. To do so is to deviate from nature's principle, and we are not above nature in this matter.

My experience of detoxicated and defatted vaccines and other mutilated products is that they are clinically inert, and I am not alone in this view. I have used immunogens, but only in three instances, so perhaps it is unfair to state the result.

With others, I await convincing clinical records, and, whilst admiring the ideal and the brilliant technique, such experience as I have leads me to be a little sceptical as to the future of "immunogens."—I am, etc.,

Eastbourne, Aug. 10th.

GEOFFREY SHERA.

### THE DEVELOPMENT OF VAGINAL OPERATIONS FOR GENITAL PROLAPSE.

SIR,—Dr. Frank A. Nyulasy (August 7th, p. 274) is quite right in his opinion that the so-called Mackenrodt's ligaments "are not mere bands of firm fibrous tissue" arising from the ischial spines and inserted into the cervix and vaginal vault. As he says, "they arise from the uterus and pass outwards to be inserted into the pelvic fascia and the lateral wall of the pelvis, and they are packed with bundles of smooth involuntary muscle fibres. . . ." This was pointed out by Eduard Martin in 1911<sup>1</sup>; and in vol. i of my *Statics* (1918), p. 263, I say: "It is, moreover, to be noticed that these thickenings,

which are most marked centrally—that is, where the cervix happens to be—all disperse and fray out peripherally." It is clear that these thickenings are not "ligaments" in the ordinary sense; nor are they "tendons,"<sup>2</sup> comparable with those we meet in relation with striated muscle. They contain, as Dr. Nyulasy asserts, much non-striped muscle, which emanates from the uterine musculature. Dr. Nyulasy, however, misses this point, that from their structure—in virtue of the non-striped muscle content—they are not capable of sustaining the pressure which during active life is continuously tending to depress the uterus, and which during growth from the infantile to the adult form not only caused the uterus, at one time an abdominal organ, to enter the pelvis, but was actually responsible for the pelvic distension—that is, of a space limited by bones.

The immediate cause of Dr. Nyulasy's letter was my statement that no one has cured a case of complete prolapse of the uterus by operating on the visceral connective tissue alone.<sup>3</sup> He states that the late Dr. Arthur Nyulasy "rectified a number of such cases by shortening the tissues alone." The abdomen was opened, the "cardinal ligaments" isolated, and "stitched (as loops) to the front of the cervix." In the same way, it may be argued that simple amputation of the cervix, or this combined with anterior colporrhaphy, is at times followed by a visceral retention; and that such result was due either to an inflammatory reaction set up or to a veritable shortening of the visceral connective tissue concerned. To have expressed myself completely, I should have added the words: "unless other factors come into play." Thus, I do not need to be assured that the procedures mentioned may cure prolapse; the state of prolapse, however, has to be defined, and the manner of living subsequently, also. Even keeping patients in bed suffices to cure "pudendal hernia" of whatever magnitude; but what we desire is a visceral retention in the presence of general activity. In this respect I have read that Dr. Stacey Wilson cured a case of protrusion by getting the patient constantly to "draw up" the parts—that is, by constantly making the movement which we all make when defaecation appears imminent and yet must be postponed.<sup>4</sup> The spectacle of complete perineal tears—that is, into the rectum—without any prolapse whatever is also before me. Palpation shows how in such cases the levator ani muscles are hypertrophied. All the time—during every minute of the day—such patients are constantly maximally contracting the levator muscles, not to prevent an exit of the uterus or of the anterior vaginal wall, but to prevent the untimely escape of rectal contents. The result is a most efficient sphincter to the pelvic outlet—a most efficient determinant of a visceral (not only of a faecal) retention. Thirdly, I have the results of my levator plastic occasionally appearing. In this, the position of the laterally displaced arm (or arms) of the pelvic floor musculature is fixed more medially—nearer the pubic arch. My cases, naturally, have been few; but the results, in spite of occasional failures, have exceeded my expectations. To cure "prolapse," or, as I call it, "pudendal hernia," we must obtain a good closure for the pelvis, either by physiological reaction or by surgical technique.

Dr. Nyulasy, however, does not refer to such a mechanism; he does not state that in the patients, on whom the procedure he refers to was performed, the pelvic outlet (which measures 4 by 5 inches) was not efficiently occluded, or did not become efficiently occluded, as a result of the treatment, of which a most essential part is the rest in bed. If a patient with a genital extrusion be kept in bed the pelvic floor aperture, stretched by the extrusion, has a chance to retract. Similarly, if visceral parts, which previously entered the aperture and caused and maintained its dilatation, are removed, and if the general health of the patient is caused to improve, the levator muscles naturally retract, the loop they form takes up a more advantageous position, and, without anything else, an improved physiological response comes into play.

<sup>2</sup> British Medical Journal, 1926, i, 502.

<sup>3</sup> Stacey Wilson: *Cure of Uterine Prolapse by Re-education of the Muscles Constricting the Vagina*, British Medical Journal, 1924, ii, 1041.

<sup>4</sup> Martin: *Der Hoftapparat der weiblichen Genitalien*, Berlin, 1911, pp. 47, 51.

I submit that if Dr. Nyulasy studies the subject closely we will find some forces at work which, judging from his letter, he has not sufficiently regarded, and perhaps not at all. The whole individual must be considered. I have laboured at this subject since 1907, and I trust not in vain. Both volumes of my *Statics* were sent to the *Medical Journal of Australia* for review. The review of the first appeared on March 22nd, 1919, and that of the second on February 13th, 1926. A perusal of these may entice Dr. Nyulasy to read these books, and if he does he will obtain more fully my point of view. If subsequently he can show I am in error I shall be grateful.—I am, etc.,

Rugby, Aug. 7th.

R. H. PARAMORE, F.R.C.S. Eng.

SIR,—I read the letter of Dr. Frank A. Nyulasy in your issue of August 7th (p. 274) with particular interest, for I had the good fortune to be the assistant of Professor W. E. Fothergill at the time he brought his operation for the cure of prolapse to its present state of perfection.

The letter calls attention to the publication about 1914 of some anatomical and other facts, which appear to call for comment.

First, from the anatomical standpoint dealing with the special supports of the uterus, we have the earlier work of Cameron, Derry, and other anatomists stating the fact that the special supports of the uterus are lateral structures in the subperitoneal tissue, and especially in connexion with the blood vessels. This work was quoted by Fothergill before the Royal Society of Medicine in December, 1907. Elliot Smith described the same structures in the *Journal of Anatomy and Physiology* (April and June, 1908). Again, in the *Journal of Obstetrics and Gynaecology* (March, 1913) Moritz published sections showing the extension of smooth muscle of the viscera into the parametrium and paracolpos.

Secondly, as to operation, the wide dissection into the lateral fornices exposing the parametrium has been carried out in Manchester since 1910. In 1913 Fothergill published in the *BRITISH MEDICAL JOURNAL* his technique in utilizing these structures in the cure of genital prolapse.

Lastly, with regard to nomenclature, let us stick to anatomical facts, and deal with parametrium and paracolpos. There is no "ligament" in question. A good deal of the work done in Manchester in this connexion appears to have escaped the notice of your correspondent.—I am, etc.,

Manchester, Aug. 14th.

JOHN WEBSTER BRIDE.

#### MINER'S NYSTAGMUS.

SIR,—In the issue of July 17th a note was published (p. 128) commenting on the unanimous conclusion of the Miners' Nystagmus Committee that the essential factor in the production of miner's nystagmus is deficient illumination. My letter of July 31st was written in support of Dr. Freeland Fergus's contention that brighter illumination was no remedy for the disease; in it I gave a very brief summary of the work I had previously done on this subject (published May 8th, 1923). I dealt with over 36,000 underground workers in the counties of Northumberland and Durham, and found that 0.90 per cent. of the coal hewers developed nystagmus during the year 1922, whereas only 0.24 per cent. of the non-hewers acquired the disease during that year. All who understand statistical methods will admit that my results definitely confute the Miners' Nystagmus Committee's conclusion as far as Northumberland and Durham are concerned, for they show that coal hewing, or something connected with coal hewing, is a far more important factor than deficiency of light in the production of the disease.

Dr. Vernon's reasoning (August 14th, p. 323) is hard to follow; he disputes my conclusion, although he admits apparently that coal hewers are more subject to nystagmus than other underground workers; I would incidentally point out, that, at any rate in our pits, where the airways are not "stone-dusted," it is the non-hewers who attend to "the props which keep the roof from falling." Had Dr. Vernon read my original paper he would have found that I had dealt with the subject of eye-strain as well as with the vision required for hewing (and, I might add, for accurately placed hammer blows), which calls for

an accurate sense of projection far more than a high macular visual acuity, as Dr. Freeland Fergus has pointed out in his instructive account of what he terms "alignment."—I am, etc.,

Newcastle-upon-Tyne, Aug. 15th.

A. S. PERCIVAL.

#### PROPHYLACTIC VACCINATION OF THE NEWLY BORN AGAINST TUBERCULOSIS.

SIR,—The editorial article in the *JOURNAL* of March 27th (p. 581), on prophylactic vaccination against tuberculosis (B.C.G.), was a guarded comment, as the results were considered incomplete.

In analysing the figures of Calmette I am struck by the very high mortality from infantile tuberculosis in France as compared with that of the cities in England; also the deaths of infants of tuberculous parents under 1 year are higher than those observed or generally notified in this country. The difficulty of diagnosis of tuberculosis in infants and the varied causes of infantile mortality render deductions from Calmette's statistics very perplexing.

When the total deaths in infants treated by Calmette's method during a definite period of a particular year are examined no appreciable difference from those treated by isolation in Paris by Professor Couvelaire is to be noted. The figures quoted in the article in the *BRITISH MEDICAL JOURNAL* are that 586 infants were vaccinated by Calmette from July, 1924, and observed by him for eighteen months; of these 96 (16 per cent.) died of various causes, and 11 (1.8 per cent.) died presumably of tuberculosis. About the same time for a similar period Couvelaire had 26 deaths (17 per cent.) out of 151 isolated babies. Thus Calmette's 17.8 per cent. total mortality was higher than Couvelaire's; 11 deaths from tuberculosis out of 167 from all causes of vaccinated infants gave 10 per cent., which is higher than that known in England for the age period. The advantage of Calmette's method was that the infant lived with the parents under probably worse conditions as a result of vaccination.

In the absence of the after-history of all the 5,182 infants vaccinated by Calmette conclusive deductions are also not possible. From the results quoted in the *Lancet* of May 29th, 1926, it is noted that the deaths from tuberculosis were smaller in the first group, which included known tuberculous contacts, than in the second group of a more recent and shorter period of observation. Thus there were 2 deaths from tuberculosis in the first group of 564 infants, of whom 231 were tuberculous contacts; the deaths from other causes were 43, and time of observation one year to eighteen months. On the other hand, in the second group of 753 infants there were 9 deaths from tuberculosis; the deaths from other causes were 53, and observation lasted six months to one year.

The following figures are typical of infantile tuberculosis deaths in our industrial areas. In Leeds, in 1924, the deaths from pulmonary tuberculosis numbered 525; the percentage of deaths at ages 1 to 5 was 2.8, and at ages 5 to 15, 4.4. The figures for Sheffield for the same year were: 447 deaths; 1.1 per cent. at ages 1 to 5, and 3 per cent. at ages 5 to 15. Taking all deaths of infants under 1 year (1924) there were 34 (1.6 per cent.) tuberculosis deaths out of 2,113 in Liverpool. The average deaths of such infants a year for six years in Leeds was 960; of these, 34 (3.5 per cent.) died of tuberculosis and meningitis. Our experience in Leeds is that the fatal type of tuberculous meningitis accounts for a high incidence of tuberculosis deaths under 1 year, generally from sources where the existence of tuberculosis is not known to the health authorities. In 1924 there were 61 deaths from tuberculous meningitis in Leeds, of which 11 were under 1 year. In 1925 the 32 deaths from tuberculous meningitis in children under 15 were traced by our nurse visitors; 7 occurred in infants under 1 year, and of these 2 only were known to have tuberculosis in the family.

Out of 464 children under 15 found tuberculous as a result of contact examination or reference by school medical officers in Leeds in 1925, only 6 died during that year; there was no death under age 5. Death notification, however, revealed over 80 deaths from tuberculosis in children under 15.

These figures seem to show that tuberculous infantile mortality is a negligible factor in our large cities for infants under 1 year. Secondly, the fatal type so prevalent is the meningeal or acute form from sources not generally known to the health authorities, rather than from tuberculous homes. Granting the effectiveness of Calmette's vaccine, unless all the babies born are vaccinated infantile deaths from tuberculosis can hardly be reduced in England. It will mean that in a city like Leeds about 8,000 babies born every year should be vaccinated to reduce the 34 deaths from tuberculosis among the 960 that die at 1 year. To vaccinate only the tuberculous contacts in English cities, who seem to acquire a better natural immunity, can hardly diminish the mortality from tuberculosis under 1 year. Nor is there any proof that as a result of vaccination incidence of or mortality from tuberculosis can be prevented in later years in those vaccinated.—I am, etc.,

Leeds.

Z. P. FERNANDEZ, M.D., D.P.H.

## OBSTETRICS IN GENERAL PRACTICE.

SIR,—It might be of interest to practitioners to see the classified statistics for puerperal sepsis in Glasgow for 1925, which were as follows:—Cases of sepsis per 1,000 confinements: midwives 7.5; maternity institutions—outdoor 11.2, indoor 16.9; doctors 12.1.

I am sure that even Dr. Munro Kerr cannot find here grounds for removing midwifery from the field of the general practitioner to the safer (!) hands of institutions and midwives.—I am, etc.,

Dennistoun, Glasgow, Aug. 11th.

JAMES COOK, M.B.

## DEFENCE OF ASSISTANTS AND LOCUMTENENTS.

SIR,—The letter in your issue of July 31st from the secretaries of the Medical Defence Union and the London and Counties Medical Protection Society, followed by the letter in your issue of August 7th from the secretary of the Medical and Dental Defence Union of Scotland, is apt to convey the impression that members of any of these bodies are completely or almost completely covered in the matter of risk arising out of the actions of their assistants or locumtenents, and Dr. Farquhar Murray has performed a valuable service in drawing attention in your issue of August 14th (p. 324) to certain weak spots in our armour in this respect.

The main lesson to be learnt is the old one that, as far as possible, every qualified medical man should be a member of one or other of these defence societies. This is especially necessary in these days when the public are much more critical than was formerly the case regarding the quality of the medical service which they receive.

But the second and almost equally important point is, as Dr. Murray emphasizes, that there should be a comprehensive reciprocal agreement between all three medical defence societies so that a principal in practice or a member of a visiting staff of a hospital should be completely covered regarding the acts of his assistants, locumtenent, or house-surgeon.

If this could be done, I am sure that it would react, not only to the benefit of the profession, but also to the benefit of the defence societies.—I am, etc.,

GILBERT I. STRACHAN, M.D., F.R.C.S.,

Honorary Secretary, Cardiff Division,  
British Medical Association

Cardiff, Aug. 8th.

## The Services.

## ARMY MEDICAL SERVICE.

## Honorary Surgeons to the King.

HIS MAJESTY has approved of the appointment of the following Major-Generals to be Honorary Surgeons to the King:

Major-General H. P. W. Barrow, C.M.G., D.S.O., O.B.E., late Royal Army Medical Corps, with effect from June 1st, 1926, in succession to Major-General C. E. Pollock, C.B., C.B.E., D.S.O., late Royal Army Medical Corps, who has retired.

Major-General D. Harvey, C.M.G., C.B.E., M.D., late Royal Army Medical Corps, with effect from July 10th, 1926, in succession to Major-General J. R. McMunn, C.B., C.M.G., late Royal Army Medical Corps, who has retired.

Major-General Barrow is Director of Hygiene at the War Office, before that he was Director of Hygiene and Pathology in India. Major-General Harvey is Director of Pathology at the War Office. When Assistant Professor in Pathology at the Royal Army Medical College in 1906 he was sent to India as a member of a commission to investigate enteric fever, and after his return was appointed a member of the Royal Society commission on sleeping sickness, and spent two years in Nyasaland.

## Obituary.

JOHN RUSSELL, O.B.E., M.B., C.M.ABERD.

Honorary Consulting Physician, North Staffordshire Infirmary.

WE regret to announce the death, on August 10th, of Dr. John Russell, formerly of Burslem, at the age of 64. Dr. Russell was born at Insch, Aberdeenshire, in 1862, and was educated at the Universities of Aberdeen and Dublin. He graduated M.A. in 1883, and M.B., C.M.Aberd. in 1886. Forty years ago he commenced general practice as assistant to Dr. Samuel Oldham at Burslem, and succeeded to the practice on Dr. Oldham's death. He was appointed assistant honorary physician to the North Staffordshire Infirmary in 1898, and later became honorary consulting physician to that institution, as well as to the Haywood Hospital, Burslem. He also held the posts of public vaccinator and police surgeon for Burslem, and medical officer to the North-East Burslem District Union. He took a keen interest in industrial disease, and was regarded as an authority on the subject of lead poisoning in particular, of which he saw many cases among the workers in the Potteries. He was the author of an important paper entitled "Basophilia in lead poisoning," which was published in the *Journal of State Medicine* in 1915. He was frequently consulted in cases of industrial disease, and his services were in constant demand by various important commercial enterprises in Staffordshire. He was an ex-president of the North Staffordshire Medical Society and of the Staffordshire Branch of the British Medical Association, as well as ex-chairman of the North Staffordshire Division.

In his younger days he was a keen member of the old Volunteers, and held a commission as captain in the Burslem Company of the 5th Volunteer Battalion of the North Staffordshire Regiment. He was prominent in Red Cross work, and for a number of years was assistant county director of the British Red Cross Society. During the war he rendered valuable service in organizing the Red Cross work in connexion with convoys to the local war hospitals, and for this and other services he was created an O.B.E. He was a prominent member of various art societies, and one of the best known public men in the Potteries. Dr. Russell is believed to have provided the original for Mr. Arnold Bennett's character of Dr. Stirling of Bleakridge, who appears from time to time in the novels of the five towns.

Owing to ill health Dr. Russell retired from practice early this year, and went to reside at Grantown-on-Spey. Before his departure from Burslem he was the recipient of presentations from the Caledonian Society, the Ceramic Art Society, the North Staffordshire Art Society, the British Red Cross Society, the Stoke-on-Trent Insurance Committee, the Burslem Golf Club, and numerous friends and patients.

## THE MEDICAL SECRETARY writes:

Dr. Russell will be a great loss to the British Medical Association, for he was for many years one of its outstanding and most stalwart supporters in Staffordshire. He represented North Staffordshire in the Representative Body from 1905 to 1923 and again in 1925. He was at the time of his death chairman of the Stoke-on-Trent Local Medical and Panel Committee, and, with the exception of 1916, had represented Stoke at the Annual Conference of Local Medical and Panel Committees since its formation. He was one of those men who rarely spoke at a conference, but those of us who knew him well realized that his influence in his own area was very great, and was always used with great effect as well as good judgement. His kindness and hospitality were unbounded, and I have more than once

pent a very happy evening with him at gatherings of the profession in Stoke and afterwards in his own house, where a "booky" man his library was irresistible. He collected books with great discrimination and had many rarities, particularly in the way of first editions of modern authors. His taste in prints and pictures also was remarkable, and it was with great pride that he took his guests into his drawing room, where he had some fine specimens of modern painters, particularly of Munnings. The news that he has left some of his money to build and endow an institute in his native village and part of his books as the basis of a library will not be surprising to those who know of his intense local patriotism, which was shared equally between the place of his birth and the town of his adoption, for the Art Gallery at Stoke is to receive a number of his valuable pictures. The sympathy of his friends will go out to his devoted niece, Miss Elsie Bissett, who took charge of his house after the death of Mrs. Russell, and to his brother, Dr. A. W. Russell of Glasgow.

J. F. HALL-EDWARDS, L.R.C.P.Ed., D.M.R.E.,  
Surgeon Radiographer, General Hospital, Birmingham.

On August 15th Dr. J. F. Hall-Edwards, one of the earliest x-ray workers in this country, died at Edgbaston.

Dr. Hall-Edwards was the son of Dr. John Edwards, who practised at Sparkbrook. He was born on December 19th, 1858, and was educated at King Edward's School and at Queen's University, Birmingham, where he was assistant demonstrator of physiology from 1880 to 1882. He settled in practice at Moseley, where he devoted his spare time to photography and photo-micrography. Fascinated by Röntgen's discovery of x rays in 1895, Dr. Hall-Edwards in 1896 took up radiography, and in 1899 was appointed radiographer to the General and the Royal Orthopaedic Hospitals in Birmingham. He was also radiographer to the Birmingham Dental Hospital and to the Birmingham and Midland Eye Hospital, and consulting radiographer to the Guest Hospital, Dudley. When the South African war broke out Dr. Hall-Edwards volunteered, and was appointed x-ray expert to the Imperial Yeomanry Hospitals at Deelfontein and Pretoria, and received the Queen's medal with four clasps. It was on his return from South Africa that Dr. Hall-Edwards began to suffer from x-ray dermatitis. He lived in constant pain for five years, and at length had his left forearm amputated. Later on similar trouble led to the amputation of the four fingers of the right hand. A Civil List pension was granted him in 1908. In spite of his disabilities he obtained a temporary commission as major in the R.A.M.C. on the outbreak of war in 1914, and acted as consulting radiographer to the First Southern and other military hospitals in the neighbourhood of Birmingham. He was also a medical examiner at the Birmingham recruiting station, addressed recruiting meetings, and organized charity performances in aid of war funds.

After the war he not only continued to practise as a radiologist; he turned his attention to municipal interests, was elected to the Birmingham City Council in 1920, and became a member of the Public Health, the Public Libraries and Museum, and the Art Gallery Committees. He was elected an honorary member of the British Medical Association at the Annual Meeting last month at Nottingham for his work and sufferings in connexion with x rays. Mr. Alfred Lucas, who expressed the thanks of the Birmingham Central Division, said that Dr. Hall-Edwards was a very loyal member of the Association, and had read many papers before his Branch and before various sections at the Annual Meetings. In 1922 Dr. Hall-Edwards was awarded the Carnegie Hero Trust medallion, together with an annuity of £100. He was ex-president of the British Electro-Therapeutic Society, vice-president of the Röntgen Society, and an honorary member of the American Röntgen Ray Society. Amongst other applications of x rays to which he gave attention was the detection of flaws in metals. As a recreation he adopted painting, using his brush by means of the thumb which remained on his right hand and an artificial finger.

ROBERT HENRY COLE, M.D., F.R.C.P.,

Physician and Lecturer in Mental Diseases, St. Mary's Hospital, Paddington.

It is with great regret that we have to record the death of Dr. R. H. Cole, which occurred on August 10th at his residence in London. He was born in 1866, and was the son of the late Mr. R. C. Cole of Ealing. Before taking up medicine he was in the civil service. He received his medical education at St. Mary's Hospital, Paddington, and took the diplomas of M.R.C.S., L.R.C.P. in 1889. In 1892 he graduated M.B. at the London University, and proceeded to the M.D. in 1895. He took the M.R.C.P. in 1896, and was elected to the Fellowship in 1917. In 1891 he became resident physician at Moorcroft Mental Hospital, and retained this position until 1907, when he started consulting practice. He threw himself with energy into his new sphere of work, and rapidly gained a reputation as a sound and reliable psychiatrist. He was appointed to the position of lecturer on mental diseases at St. Mary's Hospital, and also lectured at the Post-Graduate College, West London Hospital, and at Bethlem Royal Hospital. His other appointments included those of physician in mental diseases, St. Mary's Hospital, visitor for the Middlesex institutions for mental defectives, Home Office visitor to the State Inebriate Reformatory, and physician to the special hospital for officers, Palace Green. For several years he was examiner in psychological medicine at the University of London.

Cole was particularly interested in the administrative and legal aspects of psychiatry, and as secretary of the Parliamentary Committee of the Royal Medico-Psychological Association from 1912 to 1921, and subsequently as chairman of this committee up to the time of his death, he was responsible for much valuable work. During his period of office as chairman he rendered invaluable service in connexion with the amending bill of the Asylum Officers' Superannuation Act and the Mental Treatment Bill, and he took a prominent part in the preparation of the evidence for the Royal Commission on Lunacy and Mental Disorder. He did much good work also in connexion with the registration of mental nurses under the Nurses' Registration Act. The problem of crime in relation to insanity was one in which he was specially interested, and his views on this subject were both sound and practical.

In 1925 Cole was made president of the Psychiatric Section of the Royal Society of Medicine. For his presidential address, in which he showed a characteristic breadth of view, he chose "Progress of psychiatry" as his subject, and gave an excellent summary of the directions in which his specialty had advanced during the past few years. He was not a voluminous writer, but contributed a number of papers to the various medical journals. He was the author of a *Textbook of Psychiatry* which is now in the third edition. He was a member of the British Medical Association; and was secretary and vice-president respectively of the Section of Psychological Medicine at the Annual Meetings in 1905 at Swansea and 1909 at Belfast.

Cole will be greatly missed by a large circle of friends, and it will be difficult to fill his place in the Royal Medico-Psychological Association, for which he worked so untiringly. He was a kind, unassuming man, and extremely conscientious, thorough, and painstaking. Where patients and their relatives were concerned nothing was too much trouble, and he devoted himself unsparingly to their interests.

In 1907 he married the widow of Dr. Arthur T. White, who survives him, and to her and his son and daughter we extend our sincere sympathy.

The death occurred suddenly at Gullane on August 10th of Dr. R. J. JOHNSTON of Edinburgh; he had been ailing for a considerable time and had gone to Gullane for a rest, but his death was quite unexpected. Dr. Johnston graduated at Edinburgh University with honours in 1892, and in the course of his professional career had been connected with numerous medical institutions in the city. He was anaesthetist to the Edinburgh Dental Hospital and medical superintendent of St. Raphael's Home for

permanently disabled sailors and soldiers, an institution which was established during the later stages of the war in the Grange district of Edinburgh, and did valued and successful work for seriously injured ex-service men. As honorary physician to the Actors' and Music-Hall Artists' Association, Dr. Johnston was brought into contact with a large number of entertainers, and he was himself an agreeable raconteur and possessed a repertoire of songs which made him much sought after at social gatherings of the medical profession. Dr. Johnston is survived by a wife and four children. The interment took place at Newington Cemetery on August 13th, and was attended by a large number of friends, members of the medical profession, and a detachment of the City Police, to which Dr. Johnston had acted as a divisional surgeon.

Dr. WILLIAM ALFRED MACMAHON GARRY, who died on August 7th, in his 62nd year, at his residence in Liverpool, was educated at Queen's College, Galway, and the Catholic University of Dublin, where he obtained the diplomas L.R.C.P.I., L.R.C.S.I. and L.M. in 1889. After holding appointments in Dublin and Salford, he practised in Liverpool for forty years, and was honorary physician to the Hospital of Providence of Aigburth and visiting physician to the Priory, Allerton, for mentally deficient children, and to St. Gabriel's, Woolton. He contributed two gynaecological articles to the *BRITISH MEDICAL JOURNAL* in 1890. Dr. Garry, who had devoted himself particularly to the service of the poor in Liverpool, among whom he was very popular, had been in bad health for some time before his death.

The death is announced of Dr. MAXIME MÉNARD, who was one of the first to devote himself, some thirty years ago, to the therapeutic use of the x rays. He suffered severely from the special skin affections the rays produce, and his condition was much aggravated by his indefatigable exertions during the war. Only a few months ago we recorded the fact that he had been awarded the Legion of Honour, and had received a prize from the Académie des Sciences.

## Medical News.

THE committee of the Research Defence Society has decided to found a "Stephen Paget Memorial Lectureship," the lecturer and his subject to be connected directly or indirectly with research in order that a better appreciation of the value of medical and surgical studies may result. Each lecture, which will be given annually or biennially, at a university or other centre, will carry with it an honorarium of £20, and the expenses of the lecturer will be met by the society. Though no special appeal for funds is being made, the committee will, if desired, allocate for this purpose any donations received.

DURING next week at the Post-Graduate Hostel (Imperial Hotel, Russell Square, W.C.1) Mr. W. McAdam Eccles will open a discussion on when not to operate for hernia (Tuesday, August 24th, at 9 p.m.), and Mr. R. J. McNeill Love will open another discussion (Thursday, August 26th, at 9 p.m.) on the treatment of acute appendicitis. All medical practitioners are cordially invited. Last week Mr. A. P. Bertwistle described how the silhouette radiogram could be used in the interpretation of clinical signs. It is prepared by scratching the outline of the soft parts, which are always visible on the film of the negative, with a mounted needle before printing. This does not interfere with the bone definition, while it serves to give the less experienced observer his bearings. A radiogram so prepared demonstrates congenital deformities, such as Sprengel's shoulder, absence of the radius, spina bifida, thyro-glossal cysts; fractures such as Colles's fracture, greenstick fracture of the radius, and that of the patella due to muscular action; it shows the cause of the bulbous finger-tip and spindle-finger of periosteal whitlow and tuberculous dactylitis, and, moreover, demonstrates the presence of wasting. It indicates the depth of foreign bodies and sinuses, and for publication enhances bony definition.

THE Fellowship of Medicine announces that at Queen Mary's Hospital, Stratford, a two weeks' intensive course in medicine, surgery, and the specialties, with operations, lectures, and demonstrations in all departments of the hospital, will begin

on August 23rd. The City of London Maternity Hospital holds a special course in obstetrics each week, instruction being given during the whole day. An intensive course at the Westminster Hospital, covering all branches of medicine, surgery, and the specialties, and occupying the whole of each day, will extend from September 20th to October 2nd. On September 13th the Infants Hospital will commence a fortnight's course in the diseases of infants; lectures and demonstrations will be given each afternoon, and a visit will be paid to Thavies Inn Venereal Diseases Centre on the Sunday. At the Royal Free Hospital Dr. C. B. Heald will give four lecture demonstrations on treatment by electrotherapy on September 22nd, and the three succeeding Wednesdays, at 5.15 p.m. An ophthalmological course will be held at the Central London Ophthalmic Hospital from September 6th to October 2nd, and at the Bethlem Royal Hospital a series of lecture demonstrations will be given on Tuesdays and Saturdays at 11 a.m. from September 7th to October 2nd. An all-day course in orthopaedics will be held at the Royal National Orthopaedic Hospital from September 20th to October 2nd. Copies of all syllabuses, the general course programme, and the Fellowship journal may be obtained from the Secretary, 1, Wimpole Street, W.1.

THE Ministry of Health has issued a circular (No. 724) to local supervising authorities, which contains an explanation of the Midwives and Maternity Homes Act, 1926, Part I of which comes into force at once, and Part II, which deals with the registration of maternity homes, on January 1st next. A note on the scope of the new Act appeared in last week's issue (p. 319). The circular, which includes a form of application for the registration of a maternity home as required under the new Act, may be obtained from H.M. Stationery Office, Adastral House, Kingsway, W.C.2, price 3d. net, or through any bookseller.

THE Middlesex County Council in 1911 decided that whenever a vacancy took place the areas of the coroners for Central and East Middlesex should be combined. By the death of Mr. A. M. M. Forbes, Dr. George Alexander Cohen is now coroner for the whole division. He has also been appointed by the Crown coroner for the Duchy of Lancaster, which comprises Enfield, Southgate, and Tottenham.

THE Home Secretary gives notice that he has withdrawn from Dr. Frederick George Lewtas, M.R.C.S., L.R.C.P., the authorizations granted by the Regulations made under the Dangerous Drugs Act, 1920, to duly qualified medical practitioners to be in possession of and supply raw opium and the drugs to which Part III of the Dangerous Drugs Act, 1920, applies. Any person supplying Dr. Lewtas with raw opium or any of the drugs to which Part III of the Dangerous Drugs Act, 1920, applies will be committing an offence against the Acts.

IN a recent number of the *JOURNAL* (July 31st, p. 213) the report of the Rockefeller Foundation for 1925 was noticed, and now in rapid sequence comes the review of the work of the Rockefeller Foundation for 1925 by the president, Dr. G. E. Vincent, who gives in simple, popular language and under headings sometimes intriguing, such as "A world memory for biology," "International trade in men and ideas," and "By-products of team work," a summary of the Foundation's manifold benefactions and achievements during last year. In 1925 there were only three cases of yellow fever in all the Americas, but new cases have since been reported from North Brazil. There is good evidence that yellow fever originated in Africa and was conveyed in slave ships from the West Coast to America, where it was formerly believed to be indigenous. In July, 1925, the International Health Board established yellow fever headquarters at Lagos in Nigeria. Dr. Vincent pays a tribute to the memory of two workers for the Rockefeller Foundation—Henry R. Carter, a pioneer in yellow fever control, and Samuel T. Darling, an expert in malaria, who was killed in a motor accident in Syria. Attention is again drawn to the use of Paris green, "so fatal to the potato bug," in killing the larvae of the malaria mosquito. The campaign against hookworm disease, which is so insidious and thus contrasts with the dramatic incidence of yellow fever, was vigorously waged during 1925 in eighteen countries, where nearly a million and a half people were treated. The Foundation has to exercise discretion, and as many as 631 formal applications for help were not granted.

THE fifty-first annual report of the Mission to Lepers states that during 1925 a considerable improvement was effected in the medical equipment of the existing institutions for the treatment of lepers. In India the leper home at Purulia in Bihar is being enlarged, and new buildings were opened at Valathorasalur in Madras. A new leper hospital has been erected at Tsinan-fu in China. During the year the total number of patients under treatment in the forty-eight institutions controlled by the Mission was 7,467, while grants in aid were given to twenty-six other institutions which

accommodated 9,484 patients. The report, which is freely illustrated, is published at 6d., and together with the quarterly magazine of the Mission, *Without the Camp*, for which the subscription is 1s. a year, post free, may be obtained from the Secretary of the Mission, 33, Henrietta Street, W.C.2.

THE new regulations amending the Dangerous Drugs Regulations, the draft of which was issued in the *London Gazette* of June 4th and noted in our columns of June 12th (pp. 998 and 1001), have now been confirmed by the Home Secretary. Copies are shortly to be made available by H.M. Stationery Office.

MR. BASIL GRAVES will be the guest of honour at the thirty-first annual congress of the American Academy of Ophthalmology and Otolaryngology, to be held at Colorado Springs on September 13th. He will give an address on the surgery of senile cataract.

THE first impression of the *Theory and Practice of Radiology* by Dr. Bernard Leggett has been destroyed by fire, and the publishers, Messrs. Chapman and Hall, fear that it may be some months before the volume can be issued.

THE late Dr. William J. Miskelly of Everton, Liverpool, who died on May 13th last, left estate of the value of £10,079, with net personality £9,323. Subject to two life interests he leaves the whole of his property to the Royal Medical Benevolent Fund.

THE British Guiana Society for the Prevention and Treatment of Tuberculosis came into existence in 1907, and in its annual report for 1925 it is stated that five dispensaries and one hospital are now in active work. There is great need for a whole-time salaried medical officer for tuberculosis; at present the work of the society is being carried on voluntarily. It is hoped that an additional hospital for tuberculosis will be available very shortly. The work is maintained by grants received from the Government of British Guiana, the Georgetown Town Council, and to a smaller extent from private sources. It is added that each year between 250 and 300 people die of tuberculosis in the colony, and that more energetic preventive work is necessary.

PROFESSOR BRUMPT, member of the Académie de Médecine, has been awarded the Herbert-Fournet prize of 6,000 francs by the Société de Géographie.

THE annual meeting of the German Pediatric Society will be held at Düsseldorf from September 16th to 19th, when the following subjects will be discussed: injury to the skull at birth; the child and sport. Further information can be obtained from the secretary, Professor Goebel, Universitäts-kinderklinik, Franzosenweg, Halle.

PROFESSOR OTTO LANZ, director of the surgical clinic of the University of Amsterdam, has been made honorary doctor of medicine of Cologne University.

IT is proposed to elect seven honorary freemen of the City of Leeds; among them is Sir Berkeley Moynihan.

## REGULATIONS UNDER THE THERAPEUTIC SUBSTANCES ACT.

### ADVISORY COMMITTEE.

THE Therapeutic Substances Act, 1925, provides that the Regulations to be made under the Act should be framed by a Joint Committee consisting of the Minister of Health, the Secretary for Scotland, and the Minister of Home Affairs for Northern Ireland, and that they should have the assistance of an Advisory Committee. This has now been constituted as follows:

Sir George Newman, K.C.B., M.D., Chairman (appointed by the Minister of Health).

Mr. John Jeffrey (Scottish Board of Health).

Dr. Thomas Houston (Ministry of Home Affairs for Northern Ireland).

Dr. H. H. Dale, C.B.E., F.R.S. (Medical Research Council).

Sir Nestor Tirard, M.D. (General Medical Council).

Dr. C. O. Hawthorne, F.R.C.P. (British Medical Association).

Dr. J. H. Burn (Pharmaceutical Society of Great Britain).

Dr. J. F. Tocher (Institute of Chemistry of Great Britain and Ireland).

Dr. Houston is joint lecturer in medical jurisprudence at Queen's College, Belfast. Dr. J. H. Burn is the director of the laboratories recently established by the Pharmaceutical Society to carry out some of the tests contemplated under the Act. Dr. J. F. Tocher, F.I.C., is lecturer in statistics in the University of Aberdeen, and analyst and agricultural analyst for Aberdeen and other northern Scottish counties.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *JOURNAL*, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are *MUSEUM 9561, 9562, 9563, and 9564* (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are:

EDITOR of the *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

## QUERIES AND ANSWERS.

### ASTHMA AND BRONCHITIS.

"P." asks for suggestions in the treatment of a youth, aged 21, with chronic asthma and bronchitis; for the past four years he has tried various remedies, including a course of vaccine treatment, but the attacks tend to grow in intensity and duration.

### TREATMENT OF DYSCHESIA.

"H. M." asks whether treatment by drugs, massage, or electricity would be helpful in a case of dyschezia in a woman. The patient alternates between constipation, which makes her very uncomfortable, and diarrhoea, if purgatives are used. Glycerin and water enemata have been employed; the latter seemed to suit her best and are at present the sole form of treatment, except dieting and exercise. There seems little sign of the sigmoid colon and rectum recovering their normal tone by these measures. The patient is highly egocentric.

### URINARY STAINS.

DR. A. H. SKINNER (Hankov) asks which green or blue dye is the safest to use as a test for renal effluvia. He finds phenol red urine is tinged with blood, and small doses, is destroyed by the violet dyes that are safe and easy to detect?

### PRESERVATION OF RUBBER INSTRUMENTS.

WE have again received a question as to the best way to preserve rubber gloves and tubing. The replies to previous inquiries may be summarized as follows: Lieut.-Colonel J. A. NUNN, Army Veterinary Department, stated that he had kept rubber instruments in the plains of India throughout the hot weather in an airtight tin box with a small quantity of kerosene oil in a gallipot; the oil evaporates and must be renewed from time to time. Dr. M. ASTON KEY, Southsea, recommended swabbing five or six times a year with a saturated solution of turpentine dissolved in methylated spirit. The spirit evaporates, leaving a very fine coat of turpentine, which is quickly absorbed by the rubber; he added that when the turpentine was applied the instruments ought to be hung up and not coiled. Various chemical plans were suggested, but most of them were of cotton-wool. If old they should be plunged occasionally into hot water, well dried, wrapped again in the wool, and placed in airtight cases. Oily lubricants should not, he thought, be used for rubber catheters; he recommended a modification of Gouley's mucilaginous lubricant.

### LONGEVITY IN A FAMILY.

DR. ANDREW S. BARR (Glasgow) writes: On July 31st (p. 236) Dr. A. E. Roche gave the ages of his father's family, brothers and sisters, nine in all, with combined age of 633 years (average age over 70), and he asks "Can any reader beat this?" The answer is "Yes." My mother, aged 63 years, is the youngest of a family of nine, all of whom are alive and active. Their ages are as follows: 83, 81, 78, 76, 74, 72, 69, 67, 63. Total, 663 years. Average, 73.7.

## INCOME TAX.

## Motor Car Transaction.

"J. R. T." replaced his car in 1925 and asks whether he should have claimed any allowance as for 1925-26.

The "depreciation" or percentage allowance is a deduction from the average, and should be claimed when the return is made or at least before the assessment is confirmed, and it was to that allowance that we referred in our reply to "F. T. B." But the claim for cost of replacement or "obsolescence" is a matter to deal with when the accounts for the year in which the transaction occurred are taken into the average. Consequently, although "J. R. T." cannot now claim "depreciation" as for 1925-26, he can claim his renewal expenditure (maximum £520-£57=£463) when dealing with the results of the year 1926. On the other point mentioned, if "J. R. T." succeeded to the practice his liability for 1925-26 would strictly be on the three years' average profits of the practice which he took over, subject to a right of revision to the profits of the year; but in computing the profits of the new year the cash basis is inappropriate, and he would have to value his outstanding book debts to bring into the statement the full value of the first year's earnings.

## LETTERS, NOTES, ETC.

## THE D.P.H.

DR. HAIG (Crieff) writes: In the obituary notice of Dr. John C. McVail in your issue of August 14th, 1926, it was stated: "In 1885 McVail took the D.P.H. It was no easy thing for a busy man to do, and he gave up his time and attention to find the leisure to prepare for such an examination." As McVail was born on October 22nd, 1849, he must have been 36 at that time and 42 when in 1891 he was appointed as the first medical officer of health for the counties of Stirling and Dumfriesshire. The M.O.H. for the burgh of Crieff has had a somewhat similar experience. Dr. Gairdner, nearly four years Dr. McVail's senior, took the D.P.H. of St. Andrews University in 1912 when entering his 66th year; he had been appointed the first M.O.H. for Crieff in 1885. At the time Dr. Gairdner studied the standard of education and examination for D.P.H. had been considerably raised owing to the action of the General Medical Council. It is to the credit of both McVail and Gairdner that neither of them was under any obligation to take this diploma, which is now necessary in the case of officers holding similar appointments to theirs.

## THE MANUFACTURE OF DEGREES AND DIPLOMAS.

From time to time we have noted the existence in America of establishments for the sale of bogus degrees. Apparently this trade is not yet extinct, for a recent issue of the *Journal of the American Medical Association* contains an interesting account, with reproductions of the diplomas, of three institutions, entitled the Lincoln-Jefferson University, the University of Trinity College, and the American University (Los Angeles). The Council on Medical Education of the American Medical Association took the trouble of investigating these universities, stimulated thereto by receiving from the *Japan Medical World* photostat copies of diplomas issued to some students in Japan. These diplomas, complete with seals, crests, and signatures, would be an ornament to any consulting room. The Universitas Collegii Trinitatis professes Latin to convey to all whom it may concern its *salutem in Domino*. The Lincoln-Jefferson University is content with English. But the investigators discovered some interesting facts. Neither university has any buildings, laboratories, libraries, equipment, or even ground. Two of these institutions are housed in two small adjoining rooms in an office building in Chicago; while the third, the American University (Los Angeles), boasts of one small upper room, where the "Dean" sleeps on a dilapidated bed, when he is not carrying on the work of the university, with the help of an aged desk and a couple of chairs. The Lincoln-Jefferson University announces that, in little more than two years, degrees of thirty-eight varieties have been issued to 556 persons. In the thirty-eight varieties there have been degrees in "divinity," "theology," and "sacred theology"; in "law," "laws," "juris," "civil law," and "commercial law." In several cases the title "professor" has been granted. It is evident that our universities are behind the times in the scope they provide for the choice of a degree. This is shown, also, by the titles possessed by the two reverend heads of these universities—namely, M.A., D.D., LL.D., Ph.D., F.R.G.S., and A.K.C.I. This sort of enterprise, it would seem, is not confined to America, for there is, we gather, in Palermo an Italian Physico-Chemical Academy. Apparently the academy has been impressed by the financial possibilities of the degree-mongering methods which still exist in America. A member of the British Medical Association has received a printed letter from Professor A. Bandiera, secretary of the Academy, announcing that the council, in consideration of our member's many dignities and great learning, has resolved to nominate him an honorary member of the Academy, and to bestow on him a first-class silver-gilt medal for technical and scientific merit—price £2. The committee of the Academy contains the names of Senators, Members of Parlia-

ment, and an ex-Minister of Public Instruction. The field of activity is large, covering medicine, engineering, and the invention of chemical products and pharmaceutical preparations. The methods to be adopted are also a little mixed; they include the promotion of gymnastic and athletic clubs, the examination of food and drinking water, exhibitions of hygiene, special prizes for photography, and philanthropic work in medicine and engineering. The president of the Academy is one Professor Giuseppe Marletta, who appears to be a veritable Pook-Bah of authority. He controls the conduct of affairs, proposes new members, enforces the constitution and regulations, presides at meetings, and elects the technical committee. The technical committee is concerned with many subjects, including "medical chemistry, bromotological chemistry, clinical and biological chemistry, and docimastic chemistry." The members of the Academy are divided into six categories; every member sends a sample of his scientific, artistic, chemical, agricultural, industrial, or pharmaceutical products to the Academy's museum, and includes with these his photograph for the Academy's album. All members, honorary or otherwise, appear to pay an entrance fee of £2, in addition, presumably, to the £2 for the medal. In return they receive a diploma, bearing the seal of the Academy. For an additional two dollars a bulletin is thrown in; this subscription is obligatory, "such publication," as the prospectus says, "being greatly to the interest" of members. Recently we learnt that the American bogus-diploma merchant found a field for his efforts in Italy. Apparently the Italian is taking his revenge; but why vent it on the Britisher?

## "JOHNNIAN HOGS": AN EXPLANATION.

A JOHNNIAN writes: The review of Dr. Teichman's book, *The Cambridge Undergraduate 100 Years Ago* (August 14th, p. 309), contains the statement that "for some unaccountable reason Johnnians were always called Johnnian hogs." The nickname had died out in my time at John's (alas! nearly thirty years ago); but I have been informed that its origin was as follows: The gown of the Johnnian undergraduates is made with horizontal bars of black velvet across the sleeves—whether three or four in number, I forget. The fancied resemblance of these bars to pigs' ribs earned for Johnnians their uncomplimentary nickname. No doubt resentment of it gave rise to the custom of slitting the sleeves above the elbows, and the arms through the slits. In this way the arms of the wearer. This custom drew attention to this history of St. John's College because it is not the characters of Johnnians were the fons et origo of the nickname.

DR. M. ASTON KEY (Southsea) offers an alternative: Two theories were, he says, current in my day, the first being that the famous St. John's Bridge of Sighs was nicknamed the isthmus of Suez, and this being transliterated into Greek produced *ovos*—that is, pigs. The second derived the name from the velvet strips on the Johnnian gowns, which were known as "crackling." Apparently there is no evidence indicating which explanation is the older, but it is at least conceivable that the former grew out of the latter.

## MANIC-DEPRESSIVE PSYCHOSIS: CORRECTION.

DR. R. D. GILLESPIE (London) writes to correct a sentence in the preliminary note on the discussion of manic-depressive psychosis in the Section of Neurology and Psychology published on August 7th (p. 252). He is reported to have said that the number of cases (of manic-depressive psychosis) terminating in dementia was very small indeed. He desires it to be noted that what he said was: "The number of cases beginning as symptomatically pure manic-depressives and ending as schizophrenic dementia must be extremely small." This, he adds, is "a very different statement, and one more relevant to the discussion."

## PICTORIAL ROAD PLANS.

VOLUME VII of the Dunlop pictorial road plans, *On the Road*, describes the three main routes through East Anglia, from London through Cambridge to King's Lynn and Hunstanton, through Bishop's Stortford and Thetford to Norwich, Cromer, and Yarmouth, and through Colchester and Ipswich to Lowestoft. After a short account of places of interest in East Anglia, the routes are indicated by a thick red line running up each page, on either side of which are pictures of some of the towns or villages passed through. These neat little guides are published by E. J. Burrow and Co., Cheltenham and London, price 6d. each.

MESSRS. HAWKSLEY AND SONS, LIMITED (83, Wigmore Street, W.1), ask us to state that they are not the makers of the portable mercury sphygmomanometer noticed last week. It is made by the W. A. Baum Company of New York, and Messrs. Hawksley are agents for its sale.

## VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 36, 37, 38, 39, 42, and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 40 and 41.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 136.

## SECTION OF DISEASES OF CHILDREN.

HUGH THURSFIELD, M.D., F.R.C.P., President.

DISCUSSION ON  
ACUTE NEPHRITIS IN CHILDHOOD.

## OPENING PAPER

BY

LEONARD G. PARSONS, M.D., F.R.C.P.,  
Physician to the Children's Hospital, Birmingham.

DURING the last few years there has been a great deal of clinical and pathological research on nephritis, but the investigations have largely dealt with the manifestations of this disease in adults. The manifestations in childhood have received relatively little attention, although the problems are perhaps not so complicated as in the adult. In the adult the picture is often complicated by previous attacks, and it is difficult to estimate the etiological factor; whereas in the child the evaluation of the etiological factor is simpler, as is the problem of correlating symptoms with the structural changes, and of assessing what has been called the functional pathology of the kidney.

Whilst it is true that the problems to be faced are relatively simpler in the child than in the adult, "simple" is really the last word that can be applied to them, for they are many and varied, and many seem at the moment almost insoluble. In this discussion it will be impossible to treat the subject at all exhaustively, but a few of the problems which require solution may perhaps be indicated. What are the etiological factors of nephritis? How can the cases be classified? What is the cause of the oliguria; why does it not occur in all cases? What is the cause of the oedema? What is the cause of the critical diuresis? How many glomeruli and tubules are involved? What are the criteria of cure? Perhaps most important of all, what is the prognosis, and on what grounds can it be based? These, and very many other problems, will at once present themselves to our minds.

## CLINICAL TYPES AND CLASSIFICATION.

A survey of a series of cases of acute nephritis admitted to the Children's Hospital, Birmingham, shows that advice was sought, in by far the largest number of instances, for one of two manifestations: either the child was passing a bloody urine, or he was puffy and swollen. Occasionally the symptom for which advice was sought was vomiting, or even diarrhoea and vomiting; the latter symptoms may have preceded the occurrence of haematuria, but more frequently of oedema. These two types of onset are associated with a series of symptoms and a clinical course which serve to differentiate the cases into two groups. In the haemorrhagic and larger group the cases showed but little oedema, rarely more than some puffiness of the face, and in some cases oedema was unnoticed. Frequently the haematuria occurred after a tonsillitis. The urine showed, in addition to the naked-eye blood, albumin and casts, but neither to the degree seen in the other group of cases; the amount of urine passed was variable, but frequently was practically normal in amount, at other times there was a degree of oliguria. If oliguria occurred, a subsequent polyuria was often a marked feature, and denoted that the case was improving. The haematuria was present for a variable period, but the tendency of most of the cases was towards recovery, sometimes complete recovery.

In the oedematous group there was in many cases no previous history of disease, and oedema was the characteristic feature. This varied in amount, but was sometimes very marked, and often the only symptom of which complaint was made. The urine was usually diminished in amount, and rarely showed naked-eye blood, but frequently under the microscope showed red cells.

Casts were much more numerous than in the haemorrhagic type, pus cells were frequently a feature of the deposit, and albumin was also present in much greater amounts than in the preceding type. I have referred to the presence of vomiting, and at times of diarrhoea. The courses of these cases was longer, the tendency to recover less marked, but the tendency to become chronic more marked than in the haemorrhagic type. Other cases showed symptoms and signs which were a combination of the two types I have outlined.

Finally, there was another group of cases, which in the course of an illness such as diphtheria, scarlet fever, pneumonia, or rheumatism, either the above symptoms occurred, or routine examination of the urine showed a definite albuminuria with or without casts. It is clear, therefore, that cases of acute nephritis in children can be grouped symptomatically as either: (1) haemorrhagic; (2) oedematous or hydraemic; or (3) febrile albuminuria.

According to the modern or Cushny theory of renal secretion, when blood passes through the capillaries of the renal glomeruli an exudate consisting of water and all the crystalloid bodies of the plasma, in their respective proportions, is passed out into Bowman's capsule, by a process of physical filtration, which is modified normally by such factors as blood pressure and flow, the osmotic tension of the colloids of the blood, and the permeability of the membrane covering the capillary tuft. This glomerular filtrate, which is "practically deproteinized plasma," is modified in the tubules by the absorption of some of its contents, a function depending upon the vital activity of the tubular epithelium. The tubular epithelium takes up and returns to the blood an alkaline fluid containing in approximately the proportions in which they are present in normal plasma the threshold bodies—that is, substances, such as glucose, which do not appear in the urine unless they exceed a certain percentage or threshold value in the blood—whilst no threshold bodies such as urea are rejected and pass out into the ureter.

This theory is generally accepted as a working hypothesis except that some authorities still hold that the tubule cells secrete and do not absorb the threshold bodies; but according to some critics it does not provide a completely satisfactory explanation of certain phenomena in disease, and, as stated by Thomson, it may well be that the modern theory tells a part rather than the whole of the story of renal secretion.

Now it is universally admitted that there is a defective excretion of the threshold bodies in the oedematous or hydraemic form of nephritis; and whether we take the view that the tubules absorb or secrete these bodies it seems impossible to subscribe to the view that this defect cannot be correlated with structural damage to any particular portion of the kidney. It does appear to be a justifiable assumption that the defect in the cases which show oedema is a tubular one; and, on the other hand, its absence suggests that any damage to the tubules is slight in degree and that the origin of the blood is from some part of the kidney, in effect the glomerulus, and pathological evidence in favour of such a view is not lacking. It is, however, only fair to state that a criticism of this view has been made in a recent paper on the functional pathology of nephritis by Mayr. He states that chloride retention is not necessarily due to disease of the tubules, or may only indicate comparatively slight damage, and that therefore the conception of functional changes in the kidney must depend chiefly on the route by which protein reaches the urine. The protein is derived from blood plasma, and most or all of it passes through the glomerulus, and hence in his opinion hydraemic nephritis may be regarded as a disease mainly involving filtration. Mayr freely admits that such a view appears inconsistent with the microscopic changes found in the kidney; but as a set-off to the lack of pathological support he points out that, whatever view of the function (secretion or absorption) of the tubule cells be held, these are the cells which do the chief work of the kidney, and since urea concentration is normal in hydraemic nephritis these cells must be functioning well and able to do their work. Whilst I am ready to admit that in exudative nephritis the permeability of the capsule is altered so as to allow albumin to pass without any patho-

logical change being demonstrated in the capsule—or in other words that some functional glomerular change occurs—yet from the standpoint of the child's future surely the more important change is the structural change in the tubule. The clinician may perhaps be forgiven if he adopts the view that the change that can be seen has at least as much claim to be regarded as important as the change that cannot be seen, and that therefore he prefers to accept exudative nephritis as a tubular change, and not as a disease mainly involving filtration. According to Mayr the oedema is largely due to failure of the plasma protein to retain water in the circulation—that is, to diminution of the protein osmotic pressure, which normally tends to prevent fluid being forced into the tissues by the capillary blood pressure. He also thinks that the usual form of acute nephritis is of the hydraemic type. This is certainly not true of acute nephritis in childhood, for published statistics, and my own cases, show that by far the more frequent type is that characterized by the presence of blood and absence of any but slight oedema.

Acute nephritis in children, then, may be classified under two headings: (1) Acute haemorrhagic, or glomerular nephritis. (2) Acute exudative, hydraemic, tubular, or parenchymatous nephritis. The place of febrile albuminuria in such a classification will be considered later.

The unsatisfactory and confusing state of the classification of acute nephritis becomes obvious when an attempt is made to find out what clinical picture is described by different writers under these headings.

I will take the latest paper which has appeared on this subject, that of Paterson and Wylie. Under the title of "acute haemorrhagic nephritis" these writers give a description essentially similar to the one I have given of my own cases; they point out that these cases show no oliguria, and that the blood pressure and blood urea are not usually raised, and urea concentration is normal. The condition is regarded as probably of embolic origin, affecting a portion of glomeruli in a scattered manner. In their group of acute exudative or parenchymatous nephritis are included all cases of tubular and glomerular nephritis, post-scarlatinal nephritis being given as the best known example of the latter. Both tubular and glomerular nephritis are said to show the same symptoms, and during life it is usually conjectured whether the glomeruli or the tubules are chiefly affected. The symptoms described are the same as in my group of hydraemic cases. They found in this group that usually either the blood pressure or the blood urea is raised, and that urea concentration is impaired, and they think that the presence of toxins in the circulation is probably the cause of the kidney disorder.

From the foregoing it will be seen that although these writers state that in the haemorrhagic form the glomerulus only is affected, yet they classify glomerular nephritis with acute exudative nephritis. It is clear, however, that they realize that each of the two groups shows one distinctive feature—in the one case oedema, and in the other haematuria.

Hill gives a description of these two groups practically identical with that given by Paterson and Wylie.

Blackfan and Hamilton mean by acute glomerular nephritis a condition frequently preceded by some acute disease, in which haematuria is the striking symptom, and oedema is slight, serum protein is normal, blood urea and non-protein nitrogen tend to rise, arterial tension is raised, uraemia is not uncommon, and recurrence is rare. The characteristics of acute tubular nephritis are the absence of any history of acute infection and the presence of generalized oedema. In these cases albuminuria is marked, serum protein is low, blood urea and non-protein nitrogen are not increased, the blood pressure is not raised, uraemia is rare, and recurrence is common.

Clausen agrees with Blackfan and Hamilton, but for him, as for many of our transatlantic colleagues, parenchymatous or tubular nephritis becomes nephrosis.

The clinical pictures described by these two groups of writers are clearly fundamentally the same, and agree with my earlier statements, but they differ in relation to urea retention and increased blood pressure—for one group these are characteristics of the hydraemic, for the other of the haemorrhagic, type, and the pathology is also some-

what different. It seems possible, however, that there is an adequate explanation of the differences as regards urea retention, etc., to which reference will be made later.

Let us now, for a moment, consider the view of the pathologist as regards classification. The following classification and description of acute nephritis is that given by Shaw Dunn.

### 1. Diffuse Glomerulo-Tubular Nephritis.

**A. Glomeruli.**—A diffuse lesion of the glomeruli is the most important form of acute nephritis and is almost invariably found in cases which die of renal insufficiency, in the acute stage of the disease, but it is also often present where the nephritis appears as a complication of some septic or other infection, and is not directly the cause of death. This presumably is the type of lesion which exists during the acute stages of a large number of cases of acute nephritis, which ultimately recover. The lesion in the glomerulus may be:

(a) An intracapillary glomerulitis, showing all grades of severity, but affecting usually in similar degree every glomerulus of both kidneys. In extreme cases, especially those dying of extreme suppression of uraemia, the capillaries are so blocked that their circulation seems almost entirely checked, and in some of the severest cases the glomerular changes are entirely intrinsic.

(b) Capsulitis. In these cases, which may not differ in any clinical aspect from the foregoing, there is the appearance in the capsular space of exudates of blood fibrin and leucocytes, followed by catarrh and proliferation of glomerular and capsular epithelium, which accumulates in masses round about the tuft, often compressing it. The incidence of capsulitis varies greatly, from a few to nearly all the glomeruli.

**B. Tubules.**—The condition of tubules shows great variation. Often in cases dying of suppression they show no alteration, but lesions of all degrees may occur. The changes are more severe if there be capsulitis of the glomeruli.

### 2. Focal Glomerular Nephritis.

This is of fairly common occurrence, and may be found in forms of septic infection (so-called focal embolic type); it is best known as a complication of infective endocarditis. The essential lesion is the appearance of minute plugs of thrombin in glomerular capillaries, giving rise to necrosis, complete or partial, of the tuft, and which may be associated with more or less capsulitis, often localized over the infarcted area. These lesions are erratic in distribution and many tufts escape, while others apparently survive with partial damage. This form seldom, if ever, causes symptoms of renal insufficiency, although it may produce albuminuria and haematuria.

### 3. Acute Interstitial Nephritis.

This condition is possibly not very far removed from that of multiple pyaemic abscesses, and may occur as an early complication of scarlet fever and other streptococcal infections. As a rule the amount of undamaged renal tissue is so large that definite renal symptoms are absent, and therefore, from our point of view, this form can be disregarded.

An acute tubular nephritis without any lesion of the glomeruli can occur from chemical poisoning—for example, corrosive sublimate—but Shaw Dunn thinks that its occurrence, apart from poisoning, is rare. He does, however, state that in those cases of acute nephritis which have passed into the "nephrosis" type of subacute nephritis the tubules show marked changes and the glomeruli only slight ones, and indeed by some authorities are classified as normal, and that it is just in those cases in which the glomeruli are least certainly damaged that the symptoms are most purely hydraemic, and the tendency to uraemia and high blood pressure most in abeyance.

Muir adopts essentially the same classification, with the exception that he does admit the existence of—

### 4. Acute Catarrhal Desquamative or Tubular Nephritis.

This is a condition occurring in varying degree, as the result of acute infections, such as septicaemia and pneumonia, and is due to their toxins. It may occur in chemical poisoning. A degree of oliguria may be present.

from obstruction of the tubules by desquamated cells and extravasated red blood cells. This condition may largely be recovered from when the cause is removed.

I believe that such a classification is the best pathological one available, that it will fit most of the clinical cases, and that it can be made the basis of a clinical classification.

There is no lack of clinical evidence of the existence in childhood of a pure diffuse glomerulitis, fulminating in type, and showing the characteristic histological changes described by Shaw Dunn. Dyke has recently reported such a case in a girl aged 12 years, who during a period of five days before her death passed only five ounces of urine, which contained much blood but did not show any casts. The blood urea was 648 mg. per 100 c.cm., there was marked vomiting, a general morbilliform rash, and bleeding from the mouth and gums. The changes present in the kidneys were chiefly a diffuse intracapillary glomerulitis, but there was also some evidence of capsulitis.

In my opinion the following classification includes the various types of acute nephritis seen in childhood, and, whilst emphasizing certain clinical characters, has also pathological evidence in its favour. The retention of the terms "haemorrhagic" and "exudative" emphasizes the fact that haematuria is the characteristic symptom of the first group, oedema of the second group of cases.

1. Acute haemorrhagic or glomerular nephritis.
  - (a) Mild type (focal glomerulitis).
  - (b) Severe type (diffuse glomerulitis).
2. Acute exudative or tubular nephritis.
  - (a) Mild type.
  - (b) Severe type. This form in many cases passes on into a subacute form, and then constitutes nephrosis (Volhard and Fahr).
3. Mixed forms. A diffuse glomerulo-tubular nephritis, which in many cases goes on into a subacute or chronic form (chronic parenchymatous nephritis), and in adult life may develop into the secondary contracted kidney.

Febrile albuminuria I believe constitutes the mildest form of acute nephritis. In many febrile conditions, such as pneumonia and rheumatism, it is possible in a series of cases to find some showing albuminuria, with or without casts, others showing a transient haematuria, and again others showing an obvious acute nephritis. The transient haematuria is typically seen in acute rheumatism, the patient does not appear to be any the worse for the occurrence, and the course of the disease is not modified. The true significance of these cases does not seem to have been recognized by many writers, some of whom speak of the condition as "renal irritation." There can be no doubt, I think, that these are actually a very benign type of nephritis, and that a febrile albuminuria may represent the mildest type of haemorrhagic or glomerular nephritis.

There is good evidence for believing that a febrile albuminuria may also represent the mildest type of tubular nephritis—that is, a form in which there is no oedema, but which if the case comes to autopsy shows changes in the tubule cells. In diphtheria, albuminuria without oedema and associated with tubular changes may occur. The occurrence of these tubular changes in febrile states and diphtheria without oedema has been used by Clausen as an argument in favour of his views that the "toxin" of nephrosis affects not merely the kidney, but also the tissues in general.

To make our suggested classification, therefore, more complete a subheading "transient types" might be added to the group of acute glomerular and tubular nephritis. The recognition of the existence of this group of cases is important, for many of them pass unnoticed, or are regarded as trivial, and it is not improbable that they form the explanation of those cases of chronic nephritis which appear to arise insidiously, and also of the failure to clear up what is apparently a first attack of a frank acute tubular nephritis. In this connexion it is of interest to note that Wilcox and Lytle found, in about one-half of a series of 217 cases of acute infections, definite chemical evidence of impairment of kidney function, although many of these cases showed no clinical evidence of kidney involvement.

### *Nitrogen Retention, Blood Pressure, Uracmia.*

Reference has previously been made to the fact that nitrogen retention and raised blood pressure are stated by some writers to be characteristic of the haemorrhagic, by others of the tubular, variety of acute nephritis. It would appear that both observations are correct and that the presence of these symptoms depends entirely on the severity of the case, although the explanation of their occurrence differs in the two groups of cases. In the glomerular type they are associated with a degree of oliguria. If there be no oliguria, blood urea and non-protein nitrogen are not increased nor is the blood pressure raised. On the other hand, if there be some oliguria, the blood urea, non-protein nitrogen, and blood pressure may be raised, and uraemic convulsions may occur. Some cases of haemorrhagic nephritis, during the first few days of their illness, show a considerable diminution in the amount of urine excreted, but subsequently commence, quite abruptly, to pass large quantities of urine up to 70 ounces or more in the twenty-four hours. This "critical diuresis" is of the most favourable prognostic import, and is probably due to urea retention. I believe that the swelling of the glomerular tuft mechanically produces a retention of water, and therefore of urea, and that when the swelling becomes slightly less, so that it is possible for more water to pass from the blood into the tubule, the "head" of urea in the blood causes a diuresis.

The prognostic importance of this critical diuresis was first impressed upon me when treating cases of blackwater fever, during the late war. I noticed that cases occurred in which oliguria was pronounced, and that although the blackwater disappeared in a day or two the urine did not increase in quantity. Such cases invariably died; whereas in other cases, after a short oliguria, marked diuresis occurred, and these cases practically always recovered, even although the blackwater remained after the onset of the diuresis.

In severe cases of the tubular form of acute nephritis blood urea and non-protein nitrogen may also be increased in the early days of the attack. The probable explanation of this increase is that advanced by Shaw Dunn and Jones, who produced, by the injection of sodium oxalate intravenously into rabbits, a tubular nephritis, showing urea retention, and an initial oliguria. They point out that whether the function of the epithelium of the first convoluted tubules be regarded as absorption or secretion, the fluid in the distal portion of the first convoluted tubules contain a higher percentage of urea than the filtrate leaving the tuft—that is, the cells normally have to prevent the high percentage of urea from finding its way back into the connective tissues and vessels—and that, in view of the destructive effect of the urine on most other living tissues with which it may be brought in contact, this property of the tubule must be recognized as a very highly specialized protective quality. Now if any of the cells are killed, as happens in oxalate nephritis, the dead cells cannot prevent the filtrate, which may have been already more or less concentrated, coming into contact with the exposed connective tissue surfaces, and consequently some part of the filtrate, or even all of it, may diffuse back into the more dilute and changing tissue fluids in the supporting structures. If the cells are damaged only and not necrosed, it is probable that in so far as they are damaged they lose a proportion of their protective power. From clinical considerations it would, however, appear that these cells, except when necrosed or very severely damaged, are active enough to resist absorption of urea (cf. Mayr), although possibly unable to resist the indiscriminate absorption of threshold bodies.

On this view the occurrence of raised nitrogen in the blood in severe cases can readily be understood. The oliguria of acute tubular nephritis may also be explained in part by the same thesis. It is clear that the oliguria of acute oxalate nephritis in rabbits is not due to tension inside the capsules of the swollen kidneys, for Shaw Dunn and his co-workers have also shown that the mean circulation rate through such kidneys is greater than in normal animals. Clinical experience also suggests that oliguria in the two groups of nephritis does not admit of the same

explanation, for whereas the critical diuresis is a common mode of cure in haemorrhagic nephritis, in tubular nephritis the increase in the amount of urine passed—which, it is true, may at some time amount to a polyuria—is gradual and often unnoticed.

The occurrence of raised blood pressure in severe cases of haemorrhagic nephritis has been mentioned. According to Vollhard and Fahr a rising blood pressure precedes or is closely associated with the development of cerebral symptoms; but they cannot say whether these symptoms are secondary to the raised blood pressure or whether the cerebral symptoms and the increased blood pressure are due to circulatory disturbances in the brain. Blackfan and Hamilton have, however, clearly demonstrated that a steady rise in blood pressure is the most reliable sign of approaching uraemia. They found that patients with acute glomerular nephritis who developed uraemia showed an increase in oedema. There was a parallelism between (1) the cerebral manifestations, (2) the blood pressure, and (3) the oedema. When the blood pressure rose the patient vomited, became irritable, and complained of headache; at the same time oedema was indicated, either by an increase in the visible oedema or a gain in weight. The visible oedema was not necessarily a marked oedema. With increasing oedema and continued rise in blood pressure, visual disturbances, coma, and convulsions almost invariably followed. Decrease in oedema and fall in blood pressure were always coincident with the disappearance of cerebral symptoms. In their opinion raised intracranial tension, resulting from oedema of the brain, is the causative factor in the uraemic symptoms, and the raised intracranial pressure is the cause of the raised blood pressure. In favour of their hypothesis they quote (1) Cushing's experiments, which showed that when compression of the brain was produced in dogs the arterial pressure rose as the intracranial pressure was increased; (2) the favourable results of their treatment of uraemia by intravenous injections of magnesium sulphate; and (3) the finding in an autopsy of a case of uraemia a brain which was so oedematous and tense that when the dura mater was opened the brain literally bulged through the small incision.

In passing it may be remarked that uraemia occurring with acute nephritis is always of the type thus described, and has been labelled eclamptic pseudo-uraemia, to distinguish it from true uraemia, which is the terminal stage of chronic interstitial nephritis.

#### ETIOLOGY.

The etiology of acute nephritis presents some points of considerable interest. Marriott maintains that the symptoms of acute nephritis (glomerular and parenchymatous) are not due to renal insufficiency, but that the renal involvement is only part of a general disease, and that both forms are due to toxins, each elaborated by a more or less specific micro-organism. In glomerular nephritis the toxin, which is derived from a streptococcal infection, usually of the tonsils, acts as a capillary poison and increases the permeability of the capillary wall. In parenchymatous nephritis the toxin, which is due to a staphylococcal infection, usually of the nasal sinuses, acts by disturbing the normal physico-chemical equilibrium between the body tissue and fluids. Clausen also holds the same views; but the evidence that they produce to show that nephritis is only part of a general disease is not very convincing, especially as Marriott says that he does not include cases of nephritis in which there are bacterial embolic foci in the kidneys.

Whether the cause of acute nephritis be due to actual infection of the kidney with bacteria, or to toxin only, it is quite obvious, from a consideration of a series of cases, that the exudative type appears to arise in many instances without any obvious cause; whereas the haemorrhagic type in a very large number of cases is associated with acute infections, particularly streptococcal infections, and especially with a tonsillitis, or some infection in that area—for example, otitis media. Haemorrhagic nephritis also occurs in the course of other pyococcal infections, and I would mention in this connexion its occurrence in impetigo.

The results of bacteriological examination of the urine are variable; some authorities appear to have great difficulty in isolating organisms, others have found streptococci

and pneumococci. On the whole, my experience has been that the findings are usually negative, but in rare cases streptococci and pneumococci have been found in haemorrhagic nephritis.

Although, as I have stated, many cases of exudative nephritis do not appear to have any obvious cause, yet Clausen would have us believe that even in these a nasal sinusitis is present, for in a series comprising all the cases (11) of parenchymatous nephritis seen at the St. Louis Children's Hospital in a period of three years he found that nasal sinusitis was invariably present.

In the remarks on pathology it will have been noted that Muir regards acute tubular nephritis as due to the action of toxins. The fact that in a diffuse glomerulitis all the glomeruli are affected is easier to explain on the ground of a toxic than a bacterial cause, whereas the focal glomerular infection may conceivably be bacterial in origin. The relatively common occurrence of recovery in cases of haemorrhagic nephritis is evidence in favour of a focal and not a diffuse glomerulitis as the cause of the group of mild cases, and therefore, if the foregoing argument be correct, of their bacterial origin. It will be remembered that such an embolic origin was suggested by Paterson and Wylie.

#### PROGNOSIS.

This particular aspect of the discussion is to be considered by my colleague Dr. Smellie, and therefore I do not propose to deal with it at any great length. Complete recovery from an acute attack of nephritis is a possibility, although the tendency for the lesion to become a chronic and progressive one is well recognized. On the whole, the tendency of the mild haemorrhagic cases is towards recovery; mild exudative cases may also recover completely, but, except in the very mildest forms in this group, the tendency is towards developing into the subacute and chronic types. Indeed, as I have previously stated, it is quite possible that in many instances what is apparently a first attack of exudative nephritis is really a recrudescence of a previous mild, perhaps unnoticed, attack of nephritis. Recovery from a severe haemorrhagic or exudative attack is rare. In the former the fatal issue is more likely to occur in the acute attack, whereas in the latter the child becomes a chronic nephritic. Functional recovery, however, does appear to occur in some cases of subacute or chronic hydraemic nephritis (nephrosis) after many weeks or months, and when all hope of a favourable termination has been abandoned.

One of the most difficult problems in acute nephritis is to say whether a particular case has recovered or not. The disappearance of all symptoms and signs, and a urine free from albumin after return to full diet, and after assuming the upright position, can, of course, be taken as evidence of complete recovery. So many cases, however, show a faint haze of albumin after the disappearance of all symptoms, but in quite a fair proportion of these the urine eventually becomes albumin-free. The prognosis must be based on, amongst other things, the type and severity of the attack, persistence of red blood cells and casts, persistence and amount of albumin, the occurrence or not of a critical diuresis. The ordinary kidney function tests are, in my opinion, quite useless as a help in the prognosis of acute nephritis. In the acute stage they are valueless, and some indeed are harmful. The tests may show a deviation from the normal in cases which are passing into a subacute or chronic stage, but in these the prognosis is only too obvious. In the type of case in which help is most needed—that is, one in which recovery appears to be almost or quite complete—kidney function tests are quite useless as an index of the completeness or otherwise of the recovery, because the lesion in these circumstances is not sufficient in degree to produce anything but normal results.

Mayr has recently devised a relatively simple method of estimating the osmotic pressure of the plasma which can be used in clinical work. A determination of the osmotic pressure of the plasma may help in the prognosis of a case of acute nephritis, particularly in the early stages, and the method seems well worth investigating. The colloid osmotic pressure of the plasma appears to be exerted chiefly by the serum albumin; any form of albuminuria involves a loss of plasma protein and therefore a reduction in the

colloid pressure of the plasma. Severe cases of hydraemic nephritis are characterized by a particularly low osmotic pressure of the plasma, and if a case of acute nephritis shows a low osmotic pressure, such a case is likely to pass on into a chronic hydraemic nephritis, even if the oedema at the time of the acute attack be not very marked in degree.

In my opinion the best guide to the completeness of recovery of the kidney is by the estimation of the amount of albumin in the urine, when the latter is free from blood cells and casts. I am referring to the presence of such amounts of albumin as are too small to be estimated by an Esbach's albuminometer. The method of estimation is that introduced by my former colleague, the late Dr. J. W. Russell, and consists in comparing the albumin with a very delicate standard haze. The standard haze is practically the smallest haze recognizable in a good light against a dark background. A case can be regarded as cured when the urine is free from albumin, or when the amount of albumin is only a few units, and if this be uninfluenced by a full dietary and posture, and if the urine be free from red blood cells and casts.

In considering the question of prognosis the observations of Richards should not be forgotten. He has shown that in the frog normally only a number of glomeruli are working, but that under certain conditions fresh glomeruli become opened up—in other words, that the kidney has considerable reserve power. It is therefore possible for a functional recovery to occur in acute nephritis even although a certain number of glomeruli and tubules are permanently thrown out of action.

#### TREATMENT.

In discussing the treatment of nephritis I would lay stress on three things: (a) the necessity for rest; (b) the importance of a suitable dietary; (c) the removal of any focus of septic infection. By rest I do not mean so much any rest produced by limitation of the dietary, to which I refer later, but rest of the body as a whole, which is as essential in the treatment of acute nephritis as it is in the treatment of rheumatic heart disease. With the possible exception of the very mildest cases, the patient should be confined to bed for at least three months, and if at the end of that time the kidney responds by a noticeable increase in albumin when the patient assumes the upright position, or is given an increased dietary, the period of time in bed should be increased.

Although the present-day tendency is against a rigid milk diet in acute nephritis, I am old-fashioned enough to believe that such a diet is the most suitable. Although the excretion of protein end-products entails so little effort on the part of the kidney, and it is well known that complete "renal rest" in this sense cannot be produced even by starvation, I cannot accept the view that limitation of protein in the diet is unnecessary. For six to eight weeks the diet should consist of milk, which may be given as undiluted milk, or milk and barley water, or junket. Sugar may also be allowed as a sweetening agent, or the child may be given barley sugar. Fruit juice is also allowed as a flavouring agent, and at the end of six weeks a small amount of chocolate may be added. The first increase in food is the addition of breadcrumbs to the milk; later bread-and-butter; during the third month milk pudding, banana and cream, potato and green vegetables, and at the end of this month a small quantity of fat bacon, which should be well soaked overnight to remove as much salt as possible. During the fourth month, if the child has apparently recovered, a gradual return to the full diet is permitted. In the absence of symptoms the amount of albumin is carefully watched after each increase in diet.

The report of the Medical Research Council for the year 1924-25 contains the results of some experiments by Maclean on rabbits, which may have an important bearing on the treatment of nephritis. He found that the albuminuria, and other evidence of renal damage produced by high protein feeding, was apparently dependent on the lack of vitamins, or some other essential constituent of fresh food. When a small amount of cabbage was given no renal changes were produced, even when the animals were kept on an otherwise exclusively protein diet for

long periods. The extreme sensitiveness of the renal system to lack of vitamins was very striking, and he concludes that excessive protein feeding as such is not harmful to the kidneys. These results are of extreme interest, but they do not, of course, prove that a high protein diet can have no harmful effect on an acute nephritis. The dietary I have suggested contains a fair supply of vitamins, but in view of this investigation, green vegetable in small amounts might be introduced into the dietary at an earlier stage.

The third essential in treatment is the removal of any focus of septic infection—a point which has already been stressed. Particular attention should be paid to the condition of the tonsils, nasopharynx, ears, teeth, and to the presence of any infective skin lesion, such as impetigo. The removal of tonsils and adenoids is best deferred until the third month of the illness, because occasionally the kidney condition is for a time somewhat aggravated by the operation, but in the majority of cases no such reaction occurs.

With regard to other points in treatment, I would say that in my view attempts to relieve the kidney by increasing elimination of fluids by the skin and by the bowel are of little value; that diuretics are probably harmful and should never be used; and that in the treatment of acute nephritis drugs have no place. The only exceptions to the latter statement are the following:

1. In cases which show a considerable amount of pus in the urine alkalis—for example, sodium bicarbonate or potassium citrate—may be used in an attempt to alkalinize the urine; but the results are not very satisfactory, and I think it is probably wiser not to give them for this purpose.

2. Occasionally in the earlier stages of the disease a ketosis occurs which can be treated by glucose and sodium bicarbonate.

3. In uraemia the value of intravenous injection of magnesium sulphate is undoubted.

#### GENERAL DISCUSSION.

Dr. J. M. SMELLIE (Birmingham) said that many classifications of nephritis had been suggested, but it was unusual for any two observers to hold similar views. Until much closer correlation of the clinical picture with the true histology of the morbid process or processes was possible no classification could be considered final. Surely all forms of acute nephritis were of secondary origin. In the minority the primary focus of disease was evident, but in the majority it was concealed. From a clinical aspect a large number of the cases of acute nephritis in childhood could be sharply divided into two groups: (a) the hydraemic, oedematous, or "exudative"; and (b) the haemorrhagic; though in a review of clinical histories many mixed forms were encountered. This purely clinical classification did not enter the precincts of pathology. Many observers had called the first group alternatively "acute parenchymatous nephritis," but Dr. Smellie objected to the term "parenchymatous" in this connexion, as it suggested that the parenchymatous changes were of negligible extent or not at all present in the haemorrhagic form. The classification given by Dr. Parsons rendered this view untenable. In the prognosis of acute nephritis in children, as in classification, an appreciable divergence of opinion existed. Fowler held that in children over the age of 3 years, if there were no specially bad symptoms, recovery would almost certainly occur. Holt, on the other hand, asserted that chronic nephritis was not a very uncommon sequel of the acute form. There was further difference of opinion on the help given to prognosis by the various renal function tests. The cases that Dr. Smellie had personally investigated from the prognostic point of view fell naturally into three distinct groups—namely, early, intermediate, and late. In order to ascertain the early prognosis eleven cases treated in the General Hospital, Birmingham, during the three-year period 1922-24 and discharged as relieved were taken. One child died shortly after leaving hospital, presumably from an acute exacerbation of the disease; two were known to be quite well; two could not be traced; and the remaining six had recently been seen and examined;

the blood urea was estimated and the urea concentration test performed. Of five cases of the hydraemic type, in four the blood urea was under 35 mg. per 100 c.cm.; a boy with cardiac enlargement and raised blood pressure had a blood urea of 98 mg. Urinary examinations showed no blood or casts in any case. The urea concentration test demonstrated a defective renal function in three cases, but in two of these the urea concentration factor was up to standard. The only child who had suffered from the haemorrhagic type had, on admission, only very slight facial oedema, and, though the urine was deeply blood-stained, symptoms of threatened uraemia developed in hospital. When examined, two years after the acute disease, the systolic and diastolic blood pressures were slightly raised; there were no abnormal urinary constituents, and the blood urea and urea concentration tests were within the limits of health.

As regards intermediate prognosis Dr. Smellie quoted the case of a boy whom he had watched for six and a half years. In November, 1920, he was in a comatose condition and having frequent fits. In March, 1925, he had chorea for six weeks. During this period the blood urea was within normal limits, and there was never any evidence of cardiac affection of either a rheumatic or renal origin. The blood pressure was normal. In April, 1926, the boy, aged 13 years, looked perfectly well and fit, with a healthy cardio-vascular system. The blood urea was a little raised—namely, 57 mg.—but the urea concentration factor was only 29. The urea concentration test did not give any evidence of impaired renal function. At present the clinical condition was one of health, but the biochemical findings were at variance.

For late prognosis, unless a minimum period of ten years had elapsed since the date of the primary acute infection, no really indicative results would be forthcoming. Therefore, notes of cases of acute nephritis during the ten-year period 1906-15 inclusive were collected. Of these, 64 were of the hydraemic type and 37 of the haemorrhagic. Forty-seven of the patients were traced—32 hydraemic and 15 haemorrhagic. Twenty-three of these were known to be alive, but could not be got to come for examination, as they could see no reason for it.

Clinical examination and renal function tests—blood urea and urea concentration—were performed in sixteen cases. An average period of sixteen years had expired after their discharge from hospital. None of these patients complained of any symptoms (oedema, polyuria, headache, etc.) referable to disturbed renal function, though in all direct information on these points was invited. Only five patients had completely normal hearts, blood pressure, blood urea, urea concentration test, and urea concentration factor. The other eleven gave such diversity of clinical and laboratory findings that the results could not be correlated in any way. Clinically, judged on life insurance standards, ten of these adults were fit and well. The remaining six had slight cardiac enlargement and a raised blood pressure, notably the diastolic, but no abnormal urinary constituents. An opinion based entirely on the tests for renal function—namely, either a raised blood urea, or a low urea concentration test, or both—would have indicated six with disturbed function. Four of these, judged clinically, would have been considered normal and healthy, but the remaining two did have a raised blood pressure.

From these findings Dr. Smellie concluded that the early prognosis, judged on six cases examined eighteen months to four years after an acute nephritis, revealed only one case of clinical and biochemical findings indicative of renal damage; that in one case observed for six and a half years the boy passed through an acute pyrexial illness without any recurrence of kidney mischief; that remote prognosis is based on review of thirty-nine cases, at an average period of sixteen years after an acute nephritis. All these were to-day symptomatically well. Four had passed through pregnancy, one of whom suffered from convulsions at the time of labour. Of sixteen submitted to clinical examination and to tests for renal efficiency none had any of the urinary changes associated with a chronic nephritis. Six revealed evidence of disturbance of the cardio-vascular system, but it might not be correct to

assume that this disturbance was consequent upon the previous renal inflammation.

Dr. Smellie thought that positive biochemical results, in the absence of symptoms or physical signs, called for a further careful scrutiny of the patient and a certain guard in the prognosis until he had been observed for a longer period, but could not be taken as conclusive evidence of renal damage. He thought also that chronic nephritis was much more likely to develop from a succession of mild acute attacks—so often inadequately or totally untreated—than from one severe attack with adequate treatment. This opinion would satisfactorily account for the absence from his cases of the chronic forms of the disease, as only severe cases were admitted to hospital, and any case not definitely a primary acute attack had been excluded from consideration. His investigations had led him to the opinion that the ultimate prognosis of acute nephritis in childhood hinged entirely on the treatment that had been given. If the original acute disease received efficient treatment complete recovery would ensue in a very high proportion of cases. Conversely, the subacute and chronic varieties of nephritis encountered in early adult life were largely, if not entirely, due to inadequate treatment of the initial acute infection.

Dr. HUGH BARBER (Derby) said that twenty years ago acute nephritis in a child was regarded either as due to scarlet fever or else as idiopathic in origin. More recent investigation had demonstrated the importance of focal sepsis in the throat, nose and ears, or teeth. The cases put down as idiopathic in origin became fewer, but with their present want of knowledge they still had such a group. There did not appear to be any evidence of epidemic nephritis in children.

Acute nephritis was not very common. Dr. Parsons made an apt comparison between acute nephritis and acute rheumatism with regard to the length of rest required. It was possible to make a comparison between the two conditions so far as diagnosis was concerned. In both early diagnosis was of the utmost importance in treatment. Of the numerous complications two appeared worthy of emphasis: Pericarditis, which was fairly common, was an insidious condition giving rise to little if any pain; persistent vomiting might be the only symptom of uraemia. Persistent vomiting in a case not yet diagnosed should always suggest the necessity for examining the urine. The diagnosis of acute nephritis was made from the characteristic findings in the urine and necessitated a microscopical examination, but did not require a centrifuge or full laboratory report. Renal efficiency tests were more interesting in prognosis during convalescence, but were not sufficiently delicate to help very much. The urea concentration test did not require a clinical laboratory. It was of some value towards the later stages of convalescence. Its chief value was in helping to detect chronic interstitial nephritis, which in children might be very insidious. The estimation of urea in the blood was a useful guide to diet in all cases of nephritis, but it was only towards convalescence that any such guide was required in acute nephritis. In those cases which had progressed to an extreme degree of oedema with much albumin in the urine the blood urea was nearly always within the normal and a diet rich in protein gave the best results. Thus an estimation gave confidence in prescribing a diet which might perhaps seem rather unexpected to the parents. The prognosis, judged clinically, was serious in proportion to the length of time for which symptoms of acute trouble were present. The first sign of improvement was when diuresis took place. To obtain this improvement it was not necessary to give large quantities of fluid.

The chief essential in treatment was absolute rest in bed, warm between blankets, continued certainly until there was no longer blood in the urine, and if possible until albuminuria had cleared up; failing that, for about three months. For diet, water, fruit juice and sugar, and then diluted milk. Meat extracts should, of course, be avoided. Aperients should be mild; and for threatening uraemia, hot packs or hot-air baths were better than diaphoretic drugs. Convalescence should proceed very

gradually. Rest, iron, and suitable clothing were the indications, but the little abdominal belts worn next the skin were not healthy. It was the thighs and legs that tended to be neglected without medical advice.

Dr. HUGH T. ASHBY (Manchester) drew attention to decapsulation of the kidneys for chronic nephritis. In the type of nephritis characterized by extensive oedema, large albuminuria with casts in the urine, toxic symptoms of the uraemic type, such as vomiting, drowsiness, etc., decapsulation became a definite indication, and might promise satisfactory results when the usual line of treatment failed. Subsequent to decapsulation of the kidney a marked diuresis took place, and this diuresis might bring about much improvement in the patient's condition, and allow him to pass a crisis. Dr. Ashby mentioned the case of a child who had been under observation for a year suffering from nephritis with marked oedema. It was decided as a last resort to decapsulate one kidney, after which the patient lived for eighteen months. Previous to operation she had passed 6 to 8 ounces of urine a day. After the operation the urine increased, so that at the end of a week she was passing 30 ounces in the twenty-four hours. It was found at the necropsy that the progress of the nephritis had not been arrested. Both kidneys were finely granular and well on the way to contraction. The changes in the decapsulated kidney were, if anything, more advanced than in the other. Decapsulation was not followed by the formation of a new fibrous capsule of any considerable thickness or vascularity.

Three views had been advanced to explain the results of decapsulation: First, that by depriving the kidney of its capsule and then bringing the cortex into contact with the perinephritic tissues new vessels were formed, which anastomosed with those of the kidney itself, thus providing for the removal of inflammatory exudate and assisting in re-establishing the renal function. This view was not substantiated by the case recorded; moreover, diuresis after decapsulation was generally set up a few days after operation, long before new vessels could be formed. Secondly, it had been suggested that the rapid effects after operation were due to relief of tension. But little actual tension could be seen at the operation. The kidney did not expand and the capsule did not appear capable of resisting tension. The rapidity of expansion in cases of pyelonephrosis proved that the capsule could have little resistance to pressure from within. Thirdly, it was much more likely, as Horder suggested, that the mechanism of the production of the diuresis and disappearance of oedema was the same as in the process of the inefficient wet cupping of the past. A very effective and direct wet cupping was done to the kidney itself by decapsulating it. If this was the true explanation it was possible that simple incision of the kidney would be as effective as decapsulation.

Dr. J. C. SPENCE (Newcastle-on-Tyne) did not regard classification in acute nephritis as of much value. In infants there were two varieties—a febrile nephritis with respiratory symptoms such as bronchopneumonia, much albumin, and little oedema, and a syphilitic nephritis with oedema of the feet and anaemia, but with an absence of preceding signs of syphilis. The patient in the second case always died. In other types of nephritis classification was of no value clinically. Often haemorrhagic cases after a few weeks became hydraemic. Prognosis could only be based on clinical observation; but biochemical tests were of some value. If the blood urea began to rise it was of some importance. The methods, however, were still largely experimental. The original focus causing a nephritis was often small and easily overlooked. Dr. Spence did not agree with Dr. Parsons about protein diet, since the protein in a pint of milk was about equal to the protein in half a pound of steak; but he admitted that meat might contain other deleterious substances. In many cases of chronic interstitial nephritis there was no history of an acute attack. It almost seemed as if the condition started as a congenital abnormality.

Dr. HUGH THURSFIELD (London) said that venesection, which was formerly an almost universal treatment of acute disease of all kinds, had now all but gone out of favour.

Yet there could be no doubt of the service of timely venesection in acute oliguria in adults, and it seemed well worthy of consideration in some of the acute cases in children. Decapsulation of the kidney in acute cases possibly owed its somewhat rare successes to the principle of blood-letting; and the old practice of cupping had the same effect. Renal efficiency tests appeared to be out of favour, whether for diagnosis of types of the disease or for assisting prognosis. Dr. Thursfield thought that the standard of these tests had been insufficiently established in children, either in normal health or when the child was suffering from disease other than that of the kidney.

Dr. WILKIE SCOTT (Nottingham) thought that decapsulation was indicated (a) in hydraemic cases of prolonged duration—that is, in the large white kidney; (b) in acute nephritis with suppression, especially if there was a pre-existent chronic nephritis.

Dr. N. C. CAPON (Liverpool) discussed the classification of cases of nephritis, and emphasized the desirability of restricting the term "nephrosis" to the rare cases in which kidney degeneration (epithelial) existed without inflammatory changes. In treatment, he held that it was important to remove any septic focus without delay, even during the acute stage of nephritis; and he believed it to be probable that in the future renal decapsulation would be employed at an earlier stage in nephritis, and would not be used solely as a last resort.

Dr. J. D'EWARD (Manchester) regretted that Dr. Parsons had not condemned beef-tea more thoroughly. Women seemed to be brought up to believe that beef-tea was necessary for all sick persons. He thought that a fairly rich protein diet led to improvement in cases of nephritis; and the addition of green vegetables was probably helpful. It was difficult to get parents to understand the necessity for rest for patients who appeared otherwise healthy.

Dr. HAZEL C. GREGORY (London) had found the constipation associated with prolonged rest so troublesome that she was in the habit of getting children up sooner than had been suggested. She thought that in infancy the etiology of the skin was associated with septic patches on the skin.

Dr. PARSONS, in reply, said that renal efficiency tests were of no use in the acute stage. They were simply tests of reserve function in the kidney. In acute cases where there was no reserve, the tests were useless and possibly dangerous. He thought that not so many patients as Dr. Spence thought went on to the chronic stage. The chronic patient turned up again and again, and so produced an impression of the frequency of chronic cases. Decapsulation was somewhat outside the scope of the discussion. In the only case in which he had seen it done the kidneys were under tension, but there was less urine after the operation than before. He thought nephrosis a horrible word, and everyone differed as to its meaning. Probably it was the same thing as chronic parenchymatous nephritis. A high protein diet was suitable in chronic cases, but not in acute. Dr. Parsons agreed that tonsils and other septic foci should be removed as early as convenient; but it must be remembered that occasionally nephritis flared up afterwards.

## GOITRE IN CHILDHOOD.

BY

E. H. M. MILLIGAN, M.D., D.P.H.,  
Medical Officer of Health, Glossop.

BEFORE dealing with the question of goitre in children I would just like to say briefly, as a whole-time medical officer of health, that I recognize the need for co-operation between the health services and the general practice of medicine, and it was for this among other reasons I was present this morning. Even regarding the subject which has been under discussion, nephritis in children, which might appear purely a question for a private doctor, I found in my own district things which might be of interest

—namely, (1) a lead-soluble water supply to be one of the causes of nephritis in childhood; (2) that in my own district, which in addition to having a lead-soluble water supply has a very damp climate, the death rate of this disease was about twice that in England and Wales. Coming to the question of goitre, I consider it under various headings: its incidence as regards age, sex, and locality; conditions associated with goitre; the types of goitre; then causes, prevention, and treatment. I have only time, however, to deal very briefly with the subject.

#### Incidence.

I append details of result of the routine examination of 1,870 children in Glossop.

#### Incidence of Goitre among Glossop Children examined at Routine Inspection, 1924 and 1925.

|                        | No. Examined. | Had Goitre. |
|------------------------|---------------|-------------|
| Total boys and girls   | 1870          | 96 = 5.1%   |
| Total girls            | 937           | 75 = 8.0%   |
| Total boys             | 933           | 21 = 2.2%   |
| Girls aged 12 years    | 205           | 36 = 17.59% |
| Boys aged 12 years     | 187           | 8 = 4.2%    |
| Girls aged 13 and over | 104           | 27 = 25.9%  |
| Boys aged 13 and over  | 108           | 10 = 8.4%   |
| Boys and girls under 9 | 1143          | 9 = 0.9%    |

The percentages are for the respective groups examined.

From this table, as regards age of incidence it will be seen that under 9 years of age only 0.9 per cent. of children had goitre, whereas 8.4 per cent. of boys of 13 and 25.9 per cent. of girls of 13 had goitre, showing clearly the greater prevalence of goitre during adolescence and the greater prevalence in girls. At Bath out of 7,025 children examined a similar result was obtained. No boys under 9 years of age have been found there to have had goitre of 2,020 examined; 20 girls out of 1,904 examined had goitre; of these 20 girls, 9 were between the years of 8 and 9, at which age 748 girls were examined. Now as regards the meaning of goitre: in the above examinations at Glossop, children with visible thyroid enlargement were counted as having goitre. At the examinations at Bath only children with visible thyroid enlargement *plus* alteration of the contour of the neck or with symptoms were counted as having goitre; I found by a control examination at Bath that to compare the Glossop and Bath results it would be necessary to multiply the Bath figures by four.

#### Sex.

The table given shows also the prevalence of goitre as regards sex. The percentage of boys of 13 affected was 8.4, as compared with 25.9 of girls of the same age—that is, roughly about three times as many girls as boys were affected at Glossop. At Bath the incidence among 7,025 children examined was the same—that is, 1.5 per cent. of girls to 0.5 per cent. of boys, or 3 girls to 1 boy.

#### Locality.

I now come to locality, and give you herewith details of the prevalence of visible thyroid enlargement at 12 years of age in various districts in England and Wales. These figures are by no means complete, and I do not wish to labour the point, as Sir George Newman, chief medical officer of the Ministry of Health, will shortly be reporting fully on the matter.

#### Percentages of Visible Enlargement of Thyroid Gland at 12 Years of Age in Various Districts, 1924.

|                         | Girls. | Boys. |                    | Girls. | Boys. |
|-------------------------|--------|-------|--------------------|--------|-------|
| Glossop                 | 17.5   | 4.2   | Ripley (urban)     | 23.1   | 30.3  |
| Bath                    | 7.3    | 2.2   | Heanor (urban)     | 15.4   | 9.3   |
| Lancashire              | 12.5   | 6.3   | Clay Cross (urban) | 3.4    | 4.5   |
| Glossop-ter-hire        | 5.7    | 1.3   | Blackwell (rural)  | 2.7    | 0.7   |
| Nottinghamshire         | 13.3   | 4.7   | Bakewell (rural)   | 7.2    | 2.3   |
| Derbyshire              | 11.87  | 5.15  | Shardlow (rural)   | 12.1   | 4.1   |
| Wirksworth (one school) | 57.0   | 0.0   | Essex              | 0.61   | 0.04  |
| Ditto                   | 35.0   | 0.2   | Batley             | 5.1    | 3.9   |

At Margate goitre was almost unknown.

The table shows, however, that while at Margate and in Essex goitre is almost unknown, in Derbyshire there is an incidence of 11.8 per cent. girls and 5 per cent. boys; Nottinghamshire 13.3 per cent. girls and 4.7 per cent. boys; in Glossop 17.5 per cent. girls and 4.2 per cent. boys; in Wirksworth 57 per cent. girls and 50 per cent. boys (in one school); in Ripley 23.1 per cent. girls and 30.3 per cent. boys.

Taking the criterion of goitre as visible enlargement of the thyroid gland at 12 years of age, it can be seen that there is considerable variation in England. Goitre shows a varied prevalence in different parts of the world. Areas of great prevalence are the hilly countries, like the Alps, Pyrenees, Himalayas, and Carpathians, also the great lake region of North America. Areas of freedom from goitre are Japan and Malaya, which, it will be noted, have a marine climate.

#### Associated Conditions.

Certain conditions appear to be associated with goitre. At Glossop among 1,870 children examined I found a considerable incidence of rheumatism and diseases of the ears, nose, and throat. The following table shows this.

#### Percentage of Certain Defects in Goitrous School Children, Compared with Percentage in all Children (Goitrous and Non-goitrous), examined in 1925 and in 1924 and 1925.

| Disease or Defect.                          | Goitrous Children (120) Percentage. | All Children in 1925 (920). | Percentage in 1924 and 1925.* |
|---|-------------------------------------|-----------------------------|-------------------------------|
| Nose and throat                             | 32.2                                | 15.0                        | 14.0                          |
| Otorrhoea                                   | 1.6                                 | 0.3                         | 0.4                           |
| Rheumatism (includes "growing pains")       | 25.0                                | 5.5                         |                               |
| Chorea                                      | 0.8                                 | 0.1                         | 0.3                           |
| Mentally defective                          | 5.8                                 | 0.7 (among 2765)            |                               |
| Heart disease (functional and organic)      | 15.8                                | 16.1                        | 13.3                          |
| Definite and suspect phthisis               | 1.6                                 | 1.1                         | 1.7                           |
| Definite and suspect tuberculosis of glands | 1.6                                 | 0.5                         | 0.5                           |
| Dental decay (2 bad teeth and over)         | 28.3                                | 31.3                        |                               |

\* Total examined 1924-25, 1,870.

This table shows that diseases of the nose, throat, and ear have a much greater incidence in goitrous children than in all children (goitrous and non-goitrous), 32.2 per cent., as compared with 14. Rheumatism is also much more prevalent in goitrous children, 25 per cent. having rheumatism.

The incidence of rheumatism in the above table (25 per cent.) is startling. It must be noted, however, that rheumatism in this examination included "growing pains" as rheumatism. Of all children examined in 1925, 5.5 per cent. had rheumatism; this figure is perhaps higher than one might expect. Diseases of the ear, nose, and throat were present in 32.2 per cent. of goitrous children and 15 per cent. of all children. Mental defects were found in 5.8 per cent. of goitrous children and 0.7 per cent. of all children. In the beginning of this year I made an independent inquiry regarding rheumatism. In this inquiry I included children who had small fibrous nodules (as described by Dr. Carey Coombs of Bristol and Drs. Thomas and Coates of Bath) as rheumatic. Among 264 girls (of all ages) examined I found 19 had goitre, and among 273 boys examined 9 had goitre. Of all the children (goitrous and non-goitrous) 37 girls, or 13.9 per cent., had rheumatism, and 36 boys, or 13.1 per cent., had rheumatism. Among the goitrous children, of the 19 girls 5, or 26.3 per cent., had rheumatism, and of the 9 boys 33.3 per cent. had rheumatism.

#### Types of Goitre.

The chief types of goitre seen in childhood are simple parenchymatous and puberty hyperplasia. These two types have a negative and a positive phase—that is, there are hypothyroid symptoms associated with the goitre on the one hand, and hyperthyroid ones on the other. The hypothyroid conditions are mental dullness, dry skin and hair, chilblains, bed-wetting, and other well known conditions associated with hypothyroidism. Hyperthyroidism included conditions

such as rapid pulse, tremor, mental brightness, and a tendency to perspire. One thing I particularly want to lay stress on is that thyroid enlargement in children is a preliminary to two conditions—endemic or colloid goitre on the one hand, and toxic adenoma and Graves's disease on the other.

Regarding the association of thyroid enlargement in children with Graves's disease I would refer to the work done by Dr. Brewer of Swindon, who has carried out a large number of examinations to find the relationship between the conditions; his findings suggest that slight hyperthyroidism in childhood is a very much commoner condition than has been hitherto supposed. In my own district in Glosop I carried out an investigation of a similar kind, but I did not find hyperthyroidism present to any extent among the children. There appeared to be, on the other hand, a trend towards hypothyroid conditions. It is quite possible, however, that the tendency to hyperthyroidism varies according to locality, and that in districts where colloid goitre is prevalent the thyroid enlargement among children will be more of the hypothyroid type, whereas in areas where exophthalmic goitre is prevalent there may be hypothyroidism among children—that is, it will be the precursor of endemic goitre on the one hand, or of Graves's disease on the other. Other types of goitre in addition to those given are toxic adenoma, exophthalmic goitre, malignant goitre, and thyroiditis. Goitre may also be classified according to the pathology of the thyroid—for example, parenchymatous, colloid, adenomatous, cystic, fibrous, inflammatory, parasitic, and malignant, and goitres of the exophthalmic type. There are a number of signs and symptoms for distinguishing between all these types. Two tests are known which help to clinch the diagnosis in cases where one is doubtful of Graves's disease. The two tests are the adrenaline test and the quinine test of Bram. The former test is well known. The principle of Bram's test is that cinchonism is not caused in cases of Graves's disease by the exhibition of quinine.

#### *Causes of Goitre.*

The chief causes appear to be: (1) infective; (2) physiological, associated with an upset of glandular balance; (3) heredity; (4) strain and anxiety in the case of Graves's disease; (5) lack or excess of certain constituents in water and food or even the air, such as iodine.

I have not time to go fully into this question, but I will refer to the work of McCarrison, Lenhart, Otto Stiner, McClendon and Williams, Marine and Kimball, Cantaro, and other workers. At the recent meeting of the Royal Sanitary Institute at Derby Dr. Turton mentioned the association of goitre with water supply of a chalky nature. The balance of evidence appears to be that water pollution is associated with colloid goitre; the lack of iodine as a cause is debatable. In the investigation I made in Bath regarding goitre, pollution of water supply and verminous conditions appeared to be the chief factors at work in an outbreak in one school. Those interested in the question should read McCarrison's account of the outbreak at Sanawar, Northern India, and other details of his work; also Crotti's account of the causation of goitre and Sir James Berry's article in the *BRITISH MEDICAL JOURNAL*, December 5th, 1925.

Regarding heredity I submit details of a family in which goitre occurred for several generations.

Mrs. W., aged 59, had a large goitre, unilateral and vesicular in type. She has two children, a son with no goitre, and a daughter who is goitrous.

Mrs. W.'s mother had goitre and Mrs. W.'s mother's six sisters all had goitre. Mrs. W.'s mother had five brothers, none of whom had goitre.

Mrs. W.'s father had not got goitre. Mrs. W.'s mother had goitre, but her mother's father did not have goitre. Mrs. W.'s mother had five sons and five daughters. All the daughters had goitre but none of the sons. Among the sons' children five had goitre—all the girls; three had not goitre—the three sons. The daughters had eight children (seven girls and one boy) all of whom had goitre.

It would appear that goitre is the opposite to haemophilia, the disease occurring chiefly in females, although males may transmit it.

#### *Prevention.*

Regarding prevention, the chief means I desire to emphasize are—that infection, particularly alimentary infection, must be prevented by such means as seeing that there is a clean and satisfactory water, milk, and food supply, and that the population has a diet which contains the minimum of iodine necessary for the thyroid gland's needs (cruciferous vegetables of various kinds in particular); that there must be prevention or remedy of ear, nose, and throat diseases in children, and the prevention of overstrain, physical and mental, particularly the latter, and care after debilitating diseases. Attention must be given also to any upset of glandular balance, especially at adolescence and before and after childbirth.

Additional preventive treatment would include the recommending of a special diet containing vitamins and cod-liver oil (which contains iodine in minute quantities); cleanliness of habits; fresh air and sunshine; and removal of focal infections.

#### *Treatment.*

Iodine in some form is very beneficial; among 65 cases treated in Glosop I found 16 were cured, 36 greatly improved, and 13 unchanged. Of the unchanged cases some had been only a short time under treatment. Very careful examination had been made of all the children treated, and no symptoms of Graves's disease had been found to follow the exhibition of iodine. The removal of septic conditions was also found very helpful. A great many other medical men in America and on the Continent, as well as in England, have found iodine to be very curative. It is necessary, however, to keep the children treated under close observation, as in some instances exophthalmic symptoms have been noted to follow it. At Glosop the children are examined once a week; the following procedure is adopted. In the first instance a complete medical examination is made, and matters such as length of residence in the district, sanitary conditions and water supply, diet, etc., inquired into. After this the child is weighed weekly, and the circumference of the neck over the thyroid taken. Each child is then examined carefully for signs of incipient Graves's disease as follows; tremor is looked for by making the child stand on tip-toe with extended arms and the fingers separate one from the other; the pulse is taken, and then the child takes twelve jumps and the pulse is recorded again and counted each quarter-minute for at least forty-five seconds after; von Graefe's and Möbius's signs are also looked for. In hyperthyroidism the pulse is rapid and is not accelerated by exertion. The fine intention tremor and the other signs might also be found. Dr. Brewer, school medical officer for Swindon, gives in his annual report minute details of examination on these lines, and his results should be read by everyone interested in goitre in childhood. Treatment must also include the removal of any cause. There are, of course, other methods of treatment, such as x rays and the giving of thyroid gland.

#### *Summary.*

Goitre is not nearly so prevalent in Derbyshire now as in former years.

The beginnings of exophthalmic goitre should always be looked for in the case of the enlarged thyroids of childhood.

In Glosop in a population of 20,000 there were in round figures 12 cases of severe exophthalmic goitre and 24 of a mild type, and the deaths per year average about 0.6. These figures relate to all ages and sexes. This death rate is slightly higher than that for England and Wales.

I would like to point out also that it is highly desirable that the gap in the Insurance Act left between the ages of 14 and 16 ought to be removed, so that boys and girls will have more medical care on leaving school. The age of adolescence is a critical age for goitre as well as other diseases. In Glosop we tried to emphasize to parents the need for treatment of thyroid enlargement after leaving school.

In conclusion, owing to the association I had found of rheumatism with goitre, I would like to suggest to the British Medical Association committee investigating rheumatism that this point might be worth inquiring into.

## DISCUSSION.

Dr. L. A. PARRY (Hove) thought that the enormous variation in the figures given by Dr. Milligan as to the incidence of goitre in children—varying from practically nil in Essex and Kent to over 50 per cent. in Derbyshire—must be due to something more than mere locality, although this undoubtedly was one of the factors. In this, as in so many other investigations, the personal factor, the mentality of the investigator, must be largely concerned. Inquiries on other clinical matters had revealed the same discrepancies in figures by different observers. He agreed that the iodine treatment was the best, and had been very successful.

Dr. M. E. POPE (New South Wales) gave the results of some investigations in New South Wales. It had been found that goitre occurred in the hilly districts, while hot, dry plains and seaports were free from the disease.

Dr. H. BARBER (Derby) doubted if rheumatism was associated with goitre. Mitral stenosis or evidence of chronic valvular disease was not found in later years. Goitre was still very prevalent in Derbyshire, and he was not sure that it was decreasing at all. The public health authorities should work at the water supply rather than at giving iodine, if, as seemed probable, the water supply was at fault. There was no doubt whatever that locality was very important in relation to goitre. It was prevalent in hilly districts far from the sea.

Dr. H. W. POOLER (Stonebroom, Derbyshire) thought there was still a very great deal of goitre in Derbyshire, far more than he had observed during a long professional career in Birmingham; and he was not sure that the disease was decreasing. Fewer large unsightly wens were seen. He believed that there were many cases showing signs of derangement of function without obvious thyroid disease; this applied to hyper- as well as hypo-thyroid symptoms. Evidences of hypothyroidism could be seen in many children in the villages, ranging from mild forms with thinned coarse hair, thickened lips or alae nasi, or flattened noses or lessened mental alertness, to imbecility and full cretinism. In adults such conditions as nervous excitement, tremor, palpitation, etc., were frequent, without obvious thyroid enlargement. He could not recall seeing any case of hyperthyroidism in a child under 14 years. He believed the conditions to be due to iodine deficiency, caused by remoteness from the sea. Preventive measures suggested were the administration of iodized table salt, chocolates, or water. Iodized chocolate was much too expensive; iodizing the water supply, in view of the fact that so small a proportion of the water was used for drinking purposes, was wasteful; the best method seemed to be the use of iodized table salt.

Dr. MILLIGAN, in reply, referred to the doubts as to the decreasing incidence of goitre in Derbyshire; he had it from Dr. Nelson of Glossop, who had practised there over thirty years ago, that there had been a great decrease in the number of cases seen and the severity of the disease; Dr. Turton, speaking at the Royal Sanitary Institute meeting in Derby this year, had also expressed a similar opinion; he believed credit must be given to the late Dr. Barwise for improving the quality of water supplies in helping to effect this diminution. Regarding rheumatism and goitre, he had counted as rheumatic children who had growing pains, and in the second investigation children also who had fibrous nodules. One speaker had expressed doubts as to the reliability of percentages of goitre; Dr. Milligan said the examination was made on an agreed basis and by skilled observers; he himself had also carried out investigations in the south as well as the north. In reply to the President, Dr. Thursfield, he entirely agreed that exophthalmic goitre was rare under 14 years of age; the figures he gave (36 mild and severe cases among 20,000 persons in Glossop) referred to all ages and sexes. The point he wished to make was that thyroid enlargement might lead to exophthalmic goitre later in life as well as to endemic goitre, and the premonitory signs of both should be carefully looked for.

## SECTION OF PUBLIC HEALTH.

WILLIAM J. HOWARTH, C.B.E., M.D., D.P.H., President.

DISCUSSION ON  
POOR LAW REFORM AND PUBLIC HEALTH.

## OPENING PAPERS.

I.—J. MIDDLETON MARTIN, M.D.CAMB., D.P.H.,  
County Medical Officer of Health, Gloucestershire.

*Introduction.*

THE problem of the so-called Poor Law is the care of a section of the community which, for one reason or another, is unable to provide independently for its maintenance or, in times of illness, for the special circumstances arising therefrom, including medical care. It is a problem that has existed from the earliest times, but the nature of the problem has varied in changing social conditions. Broadly speaking, there have been four marked stages: (1) Pre-Reformation. (2) Early Reformation. (3) Industrial revolution. (4) Period of social development.

In pre-Reformation times the community as such took little, if any, heed of the needs of the necessitous, and what was provided was given by the monasteries and clergy. As Sir Francis Hyett observes in his *Gloucester in National History*:

"Work which is now done by universities and education committees, by boards of guardians, by philanthropic associations, or by individual effort, was then done exclusively by the monastic orders. For three centuries the pursuit and diffusion of knowledge was the prerogative of the Church. Statesmen and lawyers, architects and artists, schoolmasters and agriculturalists, and craftsmen, were trained in the cloister. It was monks who collected, preserved, and multiplied books, who built churches, who made roads, cut down forests, drained fens, and tilled the lands which they reclaimed. It was they who, by a systematic distribution of charity, saved the poor from starvation without the intervention of the State, and who maintained hospitals and dispensaries without subscription lists, and while they aided the onward march of contemporary civilization they have left us some priceless legacies."

In addition, the stationary poor seem to have had some sort of a legal claim on lords of manors.

*Evolution of Present-day Poor Law Services.*

In the middle of the sixteenth century there was a great upheaval of the whole social system occasioned by the Reformation, and immediately the problem of the care of the necessitous was forced on the Government of the day by their very existence and the loss of the assistance previously given by the monasteries. As a result the first Elizabethan Poor Law Act of 1553 was passed requiring "that contribution towards the relief of the impotent poor should be leviable on every competent person"—the beginning of the now well known system of rates. It was not long before amending legislation proved to be necessary, and in 1601 was passed the great charter of this branch of English law—the Poor Relief Act of 1601, which formed the basis of all Poor Law legislation for two and a quarter centuries, and a good deal of which is even now actively in force. The unit of administration was the parish.

Up to this period legislation had been very severe and repressive in character, and had failed in its purpose of reducing destitution. The new legislation was based on more humanitarian principles, though more or less deterrent treatment still obtained for the able-bodied. From time to time the problem was forced on the attention of the Government from another aspect by the epidemics of infectious disease occurring at different periods of history, and as a special example may be mentioned the Great Plague of the middle of the seventeenth century, so graphically described by Mr. Walter G. Bell. A particularly interesting side of the subject for present purposes is the evidence of activity while danger was existing, the waste of effort in the way remedy was applied, and the fading away of the lessons as soon as the immediate danger was over—but one example of many in the history of our country. Mr. Bell's account of the Plague in London is also specially interesting from the picture which he draws

of the conditions of medical practice and nursing in these days. Many other examples might be quoted, but it is sufficient evidence of the haphazard character of the relief of the necessitous and the state of curative and preventive services in those times.

Little, if any, improvement is to be noted as time went on until early in the nineteenth century, when, after industrial conditions in various directions had gradually become more and more difficult, the attention of the Government was forcibly directed to the necessity of action in regard to the poor. Meanwhile, too, extreme abuses had crept into the administration of the Elizabethan Poor Law in various directions, including the provision for the sick poor in workhouses. A Royal Commission was appointed and reported in 1832, and as an example of the condition of affairs may be mentioned their description of the state of the workhouses in the small pauperized parishes as deplorable, and of the condition of the sick poor therein as leaving much to be desired. They say, "the sick were housed with prostitutes, ex-gaolbirds, tramps, and other characters of the worst description, and their sufferings were not infrequently aggravated by the incessant ravings of some neglected lunatic." For such attention as they received they were apparently indebted to the care of less disabled paupers.

The Poor Law Amendment Act of 1834 was the outcome, and under it the care of the poor was spread over a wider area, the union of parishes with a workhouse in common, while each parish was still responsible for the expense of its own poor up to 1865.

Such is, very briefly, the history of the care of the poor up to the middle of the nineteenth century—up to the time of the Reformation a voluntary charge of the Church, then deterrent legislation, next still harsh parochial relief, and finally systematized charge spread over a group of parishes. Now the problem gradually assumed a different character from the gradual change in the social outlook, progressing with extraordinary rapidity towards the end of the nineteenth century, and especially in the past twenty-five years. As a result public opinion has led to consideration of the matter from various points of view, and amongst the more important of the bodies issuing reports on Poor Law reform may be mentioned:

- 1905. Royal Commission on the Poor Laws and Relief of Distress (reporting in 1903).
- 1908. Royal Commission on the Feeble-minded.
- 1909. Report of the Local Government Board on social conditions.
- 1911. Committee of the County Councils Association.
- 1918. Committee of the Ministry of Reconstruction.
- 1926. Memorandum of the Ministry of Health on proposals for Poor Law Reform.
- Royal Commission on National Health Insurance.
- County Councils Association.
- Association of Poor Law Unions.

Still sitting—Royal Commission on Local Government.

There is general agreement among all of them that responsibility for the care of the poor should now be spread over a much wider area, and that the direction in which the change should be made is that the charge should be laid on the authorities—county and county borough councils administering the invading social services which embrace already so much of the work of the present relief authorities.

#### Dimensions of the Problem.

The social changes and the advance of knowledge in this time have led to two important changes in the nature of the problem, especially of the care of the sick poor. The first is the dimensions of the problem, which, as will be seen from the following table, is steadily diminishing.

#### England and Wales.

|          | Population. | Paupers.  |                 |
|----------|-------------|-----------|-----------------|
| 1851 ... | 17,927,609  | 941,315   | = 5.3 per cent. |
| 1861 ... | 20,066,224  | 883,921   | = 4.4 "         |
| 1871 ... | 22,712,266  | 1,037,360 | = 4.6 "         |
| 1881 ... | 25,974,439  | 790,937   | = 3.1 "         |
| 1891 ... | 29,002,525  | 759,750   | = 2.6 "         |
| 1901 ... | 32,527,843  | 777,097   | = 2.4 "         |
| 1911 ... | 36,070,452  | 886,177   | = 2.5 "         |
| 1921 ... | 37,885,242  | 663,667   | = 1.75 "        |

In 1922 there was a sudden increase in the proportion of persons in receipt of Poor Law relief to 3.8 per cent., and in the four past years it has averaged 3.7 per cent.

It would, however, be unduly pessimistic to regard the present unfavourable conditions as other than temporary in character.

The second change is the development of social legislation and services which have invaded the province of the Poor Law and have helped to some extent in the general decrease shown above; they also provide services for persons who are above the border-line of poverty. Among these developments may be mentioned:

- 1897 Workmen's Compensation Act and subsequent Acts.
- 1902. Provision for midwifery services under Midwives Act.
- Early in twentieth century—Maternity and child welfare schemes.
- 1906. Meals for necessitous school children.
- 1908. Medical inspection of elementary school children.
- 1908. Old age pensions at 70 years of age.
- 1911. National Insurance Act.
- 1911. Unemployment Act.
- 1912. Schemes for the treatment of tuberculosis.
- 1913. Mental Deficiency Act.
- 1914. Pensions for disabilities of the great war.
- 1918. Treatment of venereal disease.
- 1918. Payment of medical fees for assistance to midwives.
- 1920. Blind Persons Act.
- 1926. Widows', Orphans', and Old Age Contributory Pensions Act.

All of these are of importance and some of them have not yet reached their full development; the most far-reaching is National Health Insurance, of which fuller mention is made later.

#### Medical Relief.

The general lines of the development to the present stage of the relief of the necessitous have been set out to show the character of the problem and the natural lines of progress, which have changed from time to time but always in the same direction from the time at which the State first assumed responsibility in the matter—a wider basis, the present stage reached being that of the union area. But, in the course of this progress, "medical relief" is a very late development, and as the Royal Commission of 1905 reported—

"the absence of reference to Poor Law medical relief in the early statutes is due in great measure to the reliance placed on voluntary association for medical relief. The hospitals received patients from the parish at fixed charges and patients generally were charged for indoor treatment. There was also a number of dispensaries in the metropolis and elsewhere."

It must also be remembered that even so late as 1858 medical practice itself was by no means clearly defined and only assumed a recognized status after the passing of the Medical Act of that year. Thus, the Royal Commission of 1905 reported to the following effect. There was no provision for a system of medical relief under the Act of Elizabeth, and even the Reform Act of 1834 did not specifically provide for a system. The Act of 1848, however, required provision to be made for medical or other assistance on account of accident, bodily casualty, or sudden illness, but it was not until 1863 that the Local Government Board had specific powers to order a board of guardians to provide surgical and medical appliances in a workhouse. Up to that time it was left to boards to make such provision as they saw fit, and from the agitation in the middle of the nineteenth century it would appear that there is grave reason for thinking that the medical care was far from satisfactory. The term "medical relief" first appears in an Order of 1842, and seems at first to have been limited to medical attendance and the usual bottle of medicine which accompanied a doctor's visit at that time. This attendance also varied according as the medical officer possessed a degree in medicine or surgery or both. They go on to say that indoor medical relief, administered under the purely deterrent principle of the workhouse system, ended in failure and was abandoned in 1867 in favour of a system in which curative treatment became the dominant principle. From that time, largely as a result of outside pressure, the standard of the care of the sick poor rose, and by the end of the nineteenth century there was little cause for serious complaint from the humanitarian standpoint, though much more was possible had full advantage been taken of medical progress.

A very interesting reference is made later by the Royal Commission of 1905 to a circular of the Poor Law Commissioners issued in 1836 and brought up to date in their

own Report. "Medical relief was to be given only in cases of actual destitution, and every endeavour was to be made to induce the labouring classes to join sick clubs or friendly societies." The numbers given for three years are:

|          | Societies. | Members.  | Paupers.  |
|----------|------------|-----------|-----------|
| 1803 ... | 9,672      | 704,350   | 1,039,716 |
| 1815 ... | ?          | 925,439   | 895,993   |
| 1904 ... | ?          | 5,700,000 | 932,000   |

Two further observations of the Commissioners may be quoted—one as a sign of the conditions of the past and the other as to their views for the future. The first is that "originally the remuneration of the medical officer was fixed by open tender," which was abolished by the General Medical Order of 1842. The second is: "We hope that, ultimately, it may be possible to dispense altogether with the service of the district medical officer and that his duties will be shared among medical men practising in the district."

Meanwhile, there had been steadily growing appreciation of two very important principles: (1) that illness and disease were important causes of pauperism, and (2) that much illness was preventable by improvement in social conditions. Many individuals might be named as pioneers in this development of knowledge, and the British Medical Association took an important share in bringing the matter before the public and the Government. A joint committee of that Association and the Social Science Association memorialized the Government in May, 1868, and as a result Mr. Disraeli appointed a Royal Commission under a Royal Warrant issued on November 24th, 1868. That Commission reported in 1871, and from the time of their report began the long series of public health legislation leading to the very wide developments of the present day. Of these health developments the most far-reaching in many respects was the National Insurance Act of 1911, the full possibilities of which have not even yet been realized.

The history of the care of the poor has been outlined—very sketchily it is true, but as fully as a paper of this character will allow—to indicate the lines on which it has developed, to show the fact that the apparent state of stability it has reached is but a stage in that development, and lastly, because its history tends to show the natural lines for further development at the present time.

#### The Problem in a County Area.

Before setting out suggestions in detail it is now desirable to consider the dimensions of the problem, and as an example the circumstances of a county area such as Gloucestershire, with a population of about 380,676, will be considered. The existing social services in addition to the "Poor Law" have been set out above and give some indication of the extent to which the province of the Poor Law has been gradually invaded.

#### Domiciliary Service.

In the county are fifteen boards of guardians with fourteen workhouses responsible for the poor amongst a population of 315,234, of which 3,959 are resident in adjoining counties; the Poor Law authorities for the remaining population of 71,401 are eight boards of guardians in adjoining counties.

The medical services and agencies available for the population of 380,676 are:

| Groups:  | Population.       | Services.   |
|--|-------------------|---|
| Insured persons ...                            | 140,000           | General domiciliary medical attendance; about half of number see doctor during any year.                                |
| Dependants ...                                 | 133,000           |   |
| Others ...                                     | 52,000            |   |
| Local medical clubs (no detailed information). |                   |   |
| Poor Law ...                                   | 8,500             | Domiciliary medical attendance (about one-third under treatment at any one time) and infirmaries                        |
| Asylum patients ...                            | 1,276             | In-patient treatment.   |
| School children ...                            | 59,000            | Treatment of a few conditions, more particularly defects of sense organs and air passages, and skin diseases and teeth. |
| Tuberculosis ...                               | Whole population. | Dispensary and sanatorium.  |
| Veneral diseases ...                           | "                 | Out-patient and in-patient at hospitals   |
| Maternity and child ...                        | "                 | Very limited treatment.   |
| War and ...                                    | "                 |   |
| Cripples ...                                   | "                 |   |
| War disabilities (numbers unknown).            |                   | A few cases only.   |

| Agencies:   | No. | Feds.       |
|---|-----|-------------|
| Hospitals—  |     |             |
| General ...   | 3   | 303         |
| Special ...   | 3   | 69          |
| Cottage ...   | 13  | 172         |
|   | 19  | 549         |
| Poor Law...   | 14  | 700 (about) |
| Infectious diseases ...   | 17  | 459 (about) |
| Tuberculosis:   |     |             |
| Sanatorium...   |     | 175         |
| Advanced beds ...   |     | 35          |
| Nursing homes ...   | 10  | 50          |
| Medical practitioners (practising) ...                                    | 212 |             |
| Dentists ...  |     | 40 (about)  |
| Nurses—district ...   |     | 140 (about) |
| Ambulances ...  |     | ?           |
| Bacteriological and pathological laboratory: Very limited and incomplete. |     |             |

It will thus be seen that for the 8,500 Poor Law persons there is available, in addition to the services of the Poor Law medical officers, treatment arrangements for many under one or other of the agencies set out in the above table. On January 1st, 1925, the distribution of the 8,500 persons in receipt of Poor Law relief was:

|  |       |  |
|--|-------|--|
| Number suffering mentally:                       |       |  |
| In institutions ...                              | 1,300 |  |
| At home ...                                      | 87    |  |
|  | 1,387 |  |
| Number suffering from sickness, infirmity, etc.: |       |  |
| In institutions ...                              | 603   |  |
| At home ...                                      | 2,065 |  |
|  | 2,668 |  |
| Number not so suffering:                         |       |  |
| In institutions ...                              | 188*  |  |
| Other persons ...                                | 785   |  |
|  | 973   |  |
| Number not so suffering at home:                 |       |  |
| Widows and wives apart ...                       | 403   |  |
| Children ...                                     | 1,140 |  |
| Others ...                                       | 1,278 |  |
|  | 2,821 |  |
| Relief on account of unemployment:               |       |  |
| Men ...  | 134   |  |
| Women ...  | 115   |  |
| Children ...                                     | 237   |  |
|  | 486   |  |
| Casuals ...                                      | 145   |  |
|  | 8,500 |  |

\* Children in specialized institutions.

For the purpose of estimating the medical assistance required, this table may be concisely summarized as follows:

|                     | No.   | Per cent. |
|---------------------|-------|-----------|
| Mentally ill ...    | 1,387 | 16.3      |
| Physically ill:     |       |           |
| In institutions ... | 603   | 7.1       |
| At home ...         | 2,065 | 24.5      |
|                     | 2,668 | 31.6      |
| Not ill ...         | 4,425 | 52.1      |
|                     | 8,500 |           |

With a view to obtaining exact information as to the numbers of sick persons undergoing treatment at any one time an inquiry was made of Poor Law medical officers in the county as to the cases in the infirmary and under treatment in their homes on January 24th, 1926, but not necessarily visited on that day, and as to the accommodation available for in-patients. The summary of the replies is:

|                                       |         |
|---------------------------------------|---------|
| Population ...                        | 309,275 |
| Workhouses ...                        | 14      |
| Total beds ...                        | 2,145   |
| Infirmary beds ...                    | 715     |
| Infirmity patients ...                | 561     |
| Patients under attendance at home ... | 750*    |

\* About 11.5 per cent. of total Poor Law persons.

As regards the nature of the illness, information was given with respect to 413 in-patients and 565 patients in their homes. It is unnecessary to set out the results in detail, but it may be briefly stated that medical attendance was required mostly on account of senility (about one-fourth of the whole), respiratory disease, largely of a chronic character (one-sixth), and diseases of the nervous system—paralysis and mental defect (about one-seventh); a total of over one-half of the cases. It is somewhat surprising to note that of 978 patients only 57 were having attention for heart disease and only 24 for malignant disease.

Of the 252 medical practitioners in the county 212 are in practice; of these, 174 are insurance practitioners and 75 are Poor Law medical officers—that is, of all the practising doctors 82 per cent. attend insured persons and 35 per

cent. attend Poor Law persons. These proportions are particularly mentioned to show that it would not entail very great changes if some arrangement were made whereby domiciliary medical attendance on Poor Law persons were distributed among all doctors willing to accept them as they do insured persons. Indeed, it would appear that the time has arrived when the anticipation of the Royal Commissioners of 1905 (made three years before the National Insurance Act) may well be realized—namely, "we hope that, ultimately, it may be possible to dispense altogether with the service of the district medical officer, and that his duties will be shared among medical men practising in the district."

This course would have great advantages over the present arrangement and would put the 8,500 so-called Poor Law persons on the same footing as the 140,000 insured persons, and would remove once for all the distinction or stigma of "Poor Law" so far as medical assistance is concerned.

In putting such a proposal into operation there are two practical difficulties. The first is the varying periods for which persons on the border-line of necessitous would require medical care, and the second is the distribution of the funds available for such care. Both these difficulties are, however, of a diminishing quantity, as the probability is that, with the full development of health insurance, the number requiring what is at present called Poor Law medical assistance will decrease; as an example it may be mentioned that an insured person is entitled to medical benefit on the insurance basis when he ceases to be an insured person and becomes an old age pensioner, in future at 65 instead of 70 years of age, and the remuneration for such medical attendance is provided from insurance funds, presumably including the share of the State contributions. Also it is to be noted that the "lives" in question are less satisfactory than the normal, and, if the remuneration is to be adequate, the capitation rate must necessarily be at a higher rate than that for insured persons. A possible manner of meeting all these difficulties would be somewhat as follows:

1. The total sum set aside for domiciliary treatment for these persons would be pooled—say, A pounds.
2. "Orders" for attendance on individuals issued by officers of the Public Assistance Authority (whatever the new authority may be) would be given to the individuals, who would choose their own doctor, the "Orders" totalling for the year, say, B.
3. The numbers of persons attended by the respective doctors will be a, b, c, d, etc.
4. At the end of a quarter or year the capitation fee available will be A pounds divided by B persons—say, C shillings.
5. The payment to each doctor will be this figure (C) multiplied by a, b, c, d.

In this way the whole amount available for medical attendance will be distributed among the doctors giving the services.

An effort has been made to calculate what the capitation rate would be at the present cost of Poor Law medical services, based on information kindly supplied by Poor Law medical officers in the county. From the return of August 4th, 1925, to the House of Commons the persons in receipt of relief on January 1st, 1925, were distributed as follows:

|                       |     |     |       |
|-----------------------|-----|-----|-------|
| In institutions:      |     |     |       |
| Mentally ill          | ... | ... | 1,300 |
| Physically ill        | ... | ... | 603   |
|                       |     |     | 1,903 |
| Others                | ... | ... | 1,118 |
|                       |     |     | 3,021 |
| Total in institutions |     |     |       |
|                       |     |     | 3,021 |
| At home:              |     |     |       |
| Mentally ill          | ... | ... | 87    |
| Physically ill        | ... | ... | 2,085 |
|                       |     |     | 2,172 |
| Not ill—general       | ... | ... | 2,821 |
| Unemployment          | ... | ... | 486   |
|                       |     |     | 3,307 |
| Total at home         |     |     |       |
|                       |     |     | 5,479 |
| Grand total           |     |     |       |
|                       |     |     | 8,500 |

The total amount of the present salaries of medical officers is £5,200, and this sum distributed over 5,479 persons gives an average of approximately nineteen shillings per head, or about double the present capitation rate. From the further information supplied by the medical officers about one-ninth of the persons are under medical attendance at

any one time; though certain information is not available, it would appear that the attendance required by this group of persons is not so greatly in excess of that given to insured persons as is generally estimated. It would, therefore, appear to be practicable to arrange a system of domiciliary medical attendance on a plan which would avoid any distinction from the ordinary population, and to give the individuals the choice of doctor.

#### In-patient Treatment.

There are in the workhouses in the county about 550 beds for sick persons, and there is also a number of beds (on the same proportion, about 120) for Gloucestershire persons in workhouses outside the county—a total of about 680. Nearly double this number of beds is available in—

|                              |     |     |       |
|------------------------------|-----|-----|-------|
| Three general hospitals      | ... | ... | 308   |
| Three special hospitals      | ... | ... | 69    |
| Thirteen cottage hospitals   | ... | ... | 172   |
|                              |     |     | 549   |
| Infectious disease hospitals | ... | ... | 450   |
| Tuberculosis:                |     |     |       |
| Sanatorium                   | ... | ... | 175   |
| Advanced beds                | ... | ... | 36    |
|                              |     |     | 211   |
|                              |     |     | 1,210 |

Presumably the present accommodation in the workhouses is sufficient in quantity, and in three of them at least, with 309 beds, is excellent in quality. Probably the remainder of the accommodation cannot be regarded as satisfactory in view of modern requirements and may need replacement. To particularize one special class of case for which beds are necessary, additional accommodation for maternity cases is required, especially in view of the housing conditions of both town and country. Some accommodation for them is already provided in the maternity wards of district nursing homes and in certain cottage hospitals, and the care of all these cases requiring special provision should be arranged in extended accommodation at the homes and hospitals.

The replacement of other Poor Law infirmary accommodation which is unsatisfactory should be undertaken gradually, and it would appear that the most satisfactory alternative provision should also be found in extensions of existing cottage hospitals and in the establishment of new ones in other parts, in many of which they are desirable for other purposes. This course would have the two great advantages of relieving the beds in general hospitals of prolonged cases and enabling more patients to have the special services available in the general hospitals, and, secondly, of removing entirely the distinction or stigma of the Poor Law from patients so treated.

#### Consultant Service.

The next requirement—a new service—is to ensure arrangements whereby consultant advice may be available as required and whereby patients in need of special treatment may proceed to the appropriate place without delay. As examples of the former may be mentioned examination by an ophthalmic surgeon and the provision of glasses, so necessary for the comfort of old persons as presbyopia comes on with age, and, of the latter, admission to hospitals for operation. The scheme for the extension of medical services in Gloucestershire makes it readily possible to put such a proposal into operation immediately, and may be given as an example of a method in which the necessary arrangements can be made at a reasonable cost.

#### Drugs.

The supply of drugs by chemists or, in distant parts, by doctors, on the lines of the insurance service, could readily be arranged.

#### Nursing.

A very important further domiciliary assistance is nursing care. Gloucestershire is very fairly covered by district nursing associations and already they provide services for the county council. It would involve a comparatively slight extension of the present arrangements of the council to include general provision of this valuable assistance to Poor Law persons, similarly in a manner which would involve no distinction of class.

*Dental.*

The provision of dental treatment cannot be arranged so easily, largely owing to the fact that dentists are not so generally distributed as are doctors—for example, there are only 40 dentists in the same area as the 212 doctors and 140 district nurses—and, further, the dentists are to be found only in the large centres of population. It is important, however, that requisite dental treatment should be provided, and possibly the solution may be found temporarily in the appointment of peripatetic dentists who will see patients in the out-stations of the Scheme for the Extension of Medical Services.

*Summary.*

Shortly, the services for the "sick poor" above outlined include:

1. Domiciliary attendance by medical practitioners, as far as possible on the lines of the present insurance medical practice, which tends towards a preventive health service.
2. In-patient treatment in hospitals (at present Poor Law infirmaries), and in additional accommodation (to replace unsatisfactory infirmaries) at existing or new cottage hospitals.
3. Consultant services—for example, ophthalmic treatment.
4. Nursing assistance.
5. Dental treatment as fully as practicable.
6. Complete arrangements under the Scheme for the Extension of Medical Services, whereby the sick poor may have immediate access to the particular form or place of treatment most appropriate to his case.

*Conclusion.*

The gradual evolution of the problem of the care of the necessitous section of the population has been briefly outlined, and it has been shown that in the course of evolution the next stage would naturally be to provide care and treatment of the sick amongst them on the lines recently developed for another large section of the community, thus avoiding the class distinction which is rightly regarded as very unfortunate.

## II.—JAMES FENTON, M.D., D.P.H.,

Medical Officer of Health, Royal Borough of Kensington.

POOR LAW REFORM AND PUBLIC HEALTH IN RELATION  
TO LONDON.

THERE are wide differences in methods of local government existing in London from those in the rest of the country, and in order to understand the problem of health administration in relation to Poor Law reform in the metropolis it will be necessary to review briefly the London system of local government.

The administrative county of London had a population at the last census of 4,484,523. It has a county council which is the local education authority controlling the school medical service. This body also supervises midwives, provides residential treatment for persons suffering from tuberculosis, has charge of the main sewers, and, although not a sanitary authority, it enforces the law in regard to offensive trades, common lodging-houses, and several other matters. The county council possesses powers somewhat similar to those of a borough council under the Housing Acts in regard to slum clearance schemes and the provision of new housing accommodation. The combination of certain of the duties usually undertaken by administrative county councils, with other duties commonly performed by local sanitary authorities, makes the administrative problems of the London County Council different from those of any other county in the country.

The Metropolitan Asylums Board provides fever hospital accommodation for the whole of the administrative county. It is an independent body, the members of which are nominated by the Ministry of Health and the Poor Law authorities of London.

The Metropolitan Water Board is a somewhat similar body to the Asylums Board, except that its members are appointed by the borough councils.

In addition to the City, which has a peculiar and distinctive position, with many powers and privileges which are not possessed by other authorities, there are twenty-eight metropolitan borough councils. The borough councils are the sanitary authorities in London and exercise the powers and duties as such under the Public Health (London) Act, 1891, and allied measures. They are also

the maternity and child welfare authorities and are responsible for the provision of the tuberculosis dispensary service.

There is a Poor Law authority in each borough, and the area in which it carries out its duties is generally co-terminous with that of the borough. Commonly the borough council and the Poor Law authority bear the same name. There are, however, a few cases where the areas of two boroughs are combined to form one Poor Law union. The London Poor Law guardians have powers almost identical with those of similar authorities in the rest of the country. One Insurance Committee serves for the entire administrative county.

It will be seen that, apart from the Water Board, there are at work in each borough five independent executive authorities (county council, borough council, Poor Law authority, Metropolitan Asylums Board, and the Insurance Committee) whose activities include health problems, and the existing more or less haphazard distribution of functions amongst them inevitably leads to loss of efficiency in administration and impedes the advance of public health. Not one of the five authorities has a complete knowledge of the whole field of work, with a consequential danger of competition and overlapping. The borough medical officer of health is not in a position to envisage as a whole the factors affecting public health in his area, nor to develop his work on the most efficient lines. The county medical officer of health and officers of the other authorities are even less able to do so, and satisfactory progress cannot, therefore, be achieved.

The present unsatisfactory position of public health administration in the metropolis is mainly due to the abandonment of the principle underlying the Public Health (London) Act, 1891—namely, that the functions of the borough councils should be executive and those of the county council almost exclusively supervisory. That policy was departed from when the school medical service, set up under the Education (Administrative Provisions) Act, 1907, was placed entirely under the direct control of the county council, to the exclusion of the borough councils.

The following examples are submitted to throw light upon what has been written:

(a) *School Medical Service.*—The school medical officers of the London County Council are out of touch with the borough medical officer of health. The majority of them are unknown to him. He has no intimate and personal knowledge of their work, he does not control their activities, and has no opportunity of co-ordinating the service with local health administration. The borough medical officer of health is deprived of the possibilities of studying and investigating health conditions amongst school children in relation to home environment by the dissociation from his department of the school medical staff, and the latter loses the stimulus derivable from maternity and child welfare work. The borough medical officer of health does not enter the schools, which are centres from which there may be a spread of infectious disease, for the prevention of which he is primarily responsible. Were the two services (local health administration and school medical service) combined, the individual's health, until the end of school life at least, would be in the charge of one set of officials, medical and other, instead of two independent authorities, with the resultant duplication of home visiting, etc.

(b) *Maternity and Child Welfare.*—While the whole service arising out of the Notification of Births Act and the Maternity and Child Welfare Act is entirely in the hands of borough councils, those authorities have no part in such ancillary work as the inspection of boarded-out children and lying-in homes, or the supervision of midwives—all of which is in the hands of the county council, to the detriment of maternity and child welfare work, and from that division of duties duplication of home visiting results.

(c) *Tuberculosis.*—Originally the whole of the administrative measures required for dealing with tuberculosis were in the hands of the borough councils and their medical officers of health. Now that the county council arranges for the admission of patients to sanatoriums and other institutions provided by other authorities, the officers of the county council decide which cases are to be admitted, and to a considerable extent investigate their after-histories. The system involves a mass of correspondence as to claims for admission, home conditions, after-care, etc., between the borough medical officer of health, and the officials of the London County Council. There is real need for simplification, and if health work were reorganized on the lines to be suggested, the two bodies—the London County

Council as supervisory and the Metropolitan Borough Council as executive—might between them evolve a scheme much less complicated.

(d) *Veneral Diseases.*—Though these diseases constitute, as a group, a factor of first-class importance to the public health, the borough authorities have no part in the scheme for their treatment, etc.

(e) *Vaccination.*—Whilst vaccination is closely associated with the prevention of infectious disease, for which borough councils are primarily responsible by statute, Poor Law guardians are responsible for operating this measure of prevention. Experience has shown that the authority responsible for the prevention of the spread of infection of small-pox should be the body responsible for operating such an important preventive measure as vaccination. The Public Health (Smallpox Prevention) Regulations of 1917 do enable the borough medical officer of health to vaccinate persons who have been in contact with small-pox patients, but vaccination is a service which should be entirely transferred to the metropolitan borough councils.

(f) *General Sanitation.*—Without going into details, mention may be made of the overlapping of jurisdiction of the county and borough councils in connexion with the Housing Acts, common lodging-houses, slaughterhouses, and cowhouses. The same remark applies to matters affecting public health connected with theatres, cinemas, and other places where the public congregate.

(g) *Registration of Births, Deaths, and Marriages.*—It is an anomaly that Poor Law guardians, whose primary duty is to relieve distress, should be responsible for the registration of births, deaths, and marriages amongst all members of the community. This duty should be transferred to metropolitan borough councils and controlled from the local town halls.

(h) *Outdoor Medical Relief.*—This service, now under the control of the Poor Law authority, is very closely wrapped up with the maternity and child welfare work of borough councils and the medical work of national health Insurance Committees. The duty of giving outdoor medical aid to those in distress would be simplified if the responsibility were transferred direct to the borough councils. The relieving officers should be placed under the control of the borough councils; they could secure the admission of persons to residential institutions for the poor in the manner now followed when officers of borough councils arrange for admission of patients to hospitals of the Metropolitan Asylums Board.

(i) *General Medicine.*—In the administration of medical treatment, maternity benefit, etc., provided under the Insurance Acts, and medical relief, care of children, etc., provided by the Poor Law, the borough councils have no part, nor are they in a position to obtain any information as to lunatics, mental defectives, and inebriates, though these and other subjects are usually regarded as parts of the general medical services, and are of high importance *qua* public health.

It will be obvious that the time has arrived when an amendment of the somewhat complicated system of local government administration in London is desirable.

The Minister of Health has recently issued provisional proposals for Poor Law reform for circulation to the various bodies concerned as a basis for consideration and discussion. The proposals for the country and for London are in the main almost identical, but in view of the widely different administration a separate set has been issued for London. Although the Minister's proposals are intended primarily to indicate a suggested method of reform of the Poor Law, they aim at securing simplification of the whole of the health administration work carried out by the various local authorities operating in London. The proposals contemplate that the London County Council will undertake for the whole administrative county—

(a) The general oversight of the administration of all health services, and the duty of acting in place of a metropolitan borough council declared to be in default of any of these services.

(b) The complete responsibility for outdoor relief (including domiciliary medical relief).

(c) The control of all residential institutions transferred under the reform scheme from the Poor Law authorities to the county council.

(d) The services at present maintained by the Metropolitan Asylums Board.

(e) The duties in connexion with vaccination now undertaken by the Poor Law authorities.

It is also proposed that certain anomalies of historical origin, such as the association of registration of births, deaths, and marriages with the provision for the relief of the poor, should be corrected, and it is intended that there

shall be an improved correlation between Poor Law relief and unemployment benefit.

It is a principle which will generally be accepted by those intimately concerned in public health work that so far as the health of the individual is concerned the best results are only to be obtained if he remain under the supervision of one single authority throughout the course of his life. The transfer of supervision, as at the present time, from the "maternity and child welfare" authority to the "education" authority, later to the "insurance" authority, and in times of distress or when suffering from infectious illness to the "Poor Law" or "fever" authority, affects adversely the individual, leads to wasteful expenditure and confused administration, and interferes with the progress of each of the authorities, none of which derives the full amount of experience that might be obtained.

There is no doubt that it would be to the general benefit that public health administration should aim definitely at the establishment of a single authority in each area charged with all executive health functions; but in London, with a population of four and a half millions, this would prove a task insuperable for one body. There is, however, much to be said in favour of securing simplicity and efficiency in administration by transferring the duties of the London Insurance Committee, the Metropolitan Asylums Board, and the Poor Law authorities within the county of London to the County Council and the metropolitan borough councils. The Metropolitan Asylums Board organization and the Poor Law residential institutions should be transferred to the County Council, thus allowing one body to control the residential institutional treatment for the whole of London. The services now being carried out by the London Insurance Committee and those of a non-residential institutional character now being administered by the Poor Law authorities should be transferred to the metropolitan borough councils.

In London Poor Law institutions there are approximately 46,800 beds, and in the Metropolitan Asylums Board institutions approximately 23,000 beds. Some idea of the task which would fall on the County Council if it were called upon to control this large number of beds, in addition to continuing its present duties, can be gathered when it is remembered that the total number of beds in the voluntary hospitals in London is only 13,000.

If the London County Council were made the authority for residential institutional treatment for London it would probably be impossible for that authority to carry out satisfactorily local health executive duties of a non-residential character, and, further, it is in the interests of the health of the individual that these duties should be in the hands of the local sanitary authorities. It would appear, therefore, necessary and desirable to add to the present powers of the metropolitan borough councils by charging them definitely with the duty of carrying out all local health services of a non-residential character.

This proposal would involve the transfer to the borough councils of all non-residential executive health functions now in the hands of the London County Council, such as the school medical service, the inspection of common lodging-houses, and the supervision of midwives. Each borough council would be entrusted, in addition, with the work of the medical and other staffs (except the residential institutional staffs) of the Poor Law guardians; the registration of births, deaths, and marriages; vaccination; and the work of the London Insurance Committee within its area.

Thus in London we should have the metropolitan borough councils acting as the local health executive authorities and the London County Council as the institutional authority for Poor Law, infectious disease, and tuberculosis. The County Council would also remain the supervisory and co-ordinating authority with regard to health services generally; but it is essential that the county authority should be entirely supervisory in regard to local health matters rather than partially executive and partially supervisory. The London County Council could, in fact, act as a Provincial Board of Health for London, thus relieving the Minister of Health of much of the detailed work now falling upon him. Under these proposals the two authorities, working closely together, would operate in each area, instead of five as at present.

It is only by such distribution of functions as that outlined that metropolitan public health administration can become efficient, elastic, and capable of fullest development. In this way only can administration be really democratic, enabling the citizens of each borough to have easy access to local representatives and responsible officers in their own areas, for central executive administration over an area so vast as the metropolis must, of necessity, be bureaucratic.

### III.—R. P. GARROW, M.D. ABERD., D.P.H.,

Medical Officer of Health, Municipal Borough of Chesterfield.

#### FROM THE POINT OF VIEW OF THE NON-COUNTY BOROUGH OR URBAN DISTRICT.

The provisional proposals for Poor Law reform prepared in the Ministry of Health for circulation to the London County Council, associations of local authorities, and others concerned, as a basis for consideration and discussion, have fallen like a bombshell upon non-county boroughs and urban districts throughout England and Wales.

The principal proposal affecting non-county boroughs and urban districts—namely, that the county council is to be the supervising and controlling authority for all health purposes throughout the administrative county—is the cause of profound consternation to members and officials of municipal boroughs and urban districts. Commenting on this, the council of the Association of Municipal Corporations, in its annual report, says:

"It will be apparent to members of the association that these are proposals to which the association could not possibly assent. Some non-county boroughs have been in existence for centuries, and most of them have been exercising health functions for many years before county councils were created. In the opinion of the Council, the borough councils are well able to discharge their duties in this respect, and it would be entirely contrary to their interests and to the public interests that they should be placed under the control of the county councils. Moreover, dual responsibility, which is involved in the proposal of the Ministry, is open to grave objection."

Having regard to the objects sought to be attained by the reforms—namely, unification and co-ordination and the prevention of overlapping—the proposal to put all borough and urban and rural district councils under the county councils is difficult to understand. The Ministry's memorandum says:

"As regards the counties, the problem of administration is complicated (a) by the size of the areas involved; and (b) by the present existence in every part of the administrative counties of two authorities (the county council and a borough or district council), each of which has functions in regard to health to perform."

But neither the unwieldy size of the counties nor the divided authority throughout their areas is in any way mitigated by the proposal that—

"the county council shall in all cases definitely undertake for the whole administrative county—

(a) A general oversight of the administration of all health services, whether existing or transferred, and a duty of acting in the place of a borough or district council declared to be in default in any of those services, and

(b) a complete responsibility for (1) the consideration of applications for relief and the grant of outdoor relief (or home assistance) (including domiciliary medical relief), and (2) all institutions transferred under the reform scheme and the uses to which these institutions are put."

Both difficulties would be accentuated by the proposed reforms. If the administrative counties are generally too large for the efficient discharge of the present health functions of the county councils, they will be still more unwieldy if the county councils attempt general supervision and control of all health services throughout their entire areas. The complications arising from the present existence in every part of the administrative counties of two authorities responsible for different health services are generally trifling compared with the possibilities of friction under a system in which every health function became subject to dual control.

Counties and county boroughs have come to be regarded as the most suitable areas of local administration, and all the more important developments in public health in recent years are administered by the county councils and county borough councils. Everybody is agreed that the county

borough presents the closest approach to the ideal unit for health administration in this country, but we are very far from a similar unanimity in regard to the counties.

The non-county boroughs and urban districts, of which there are twenty-two amongst the "great towns" of England and Wales with populations of over 50,000, resent exclusion from participation in modern health developments.

Their natural aspirations towards the complete autonomy in local affairs by acquiring county borough powers have had a serious set-back by the recommendation of the present Royal Commission on Local Government that the minimum population entitling a borough to apply for county borough status should be raised from 50,000 to 75,000. But the proposals for Poor Law reform are a still more serious menace to the prestige of these towns, and have stimulated the council of the Non-County Borough Association to pass the following resolution unanimously:

"That this Association will resist to the uttermost any further encroachments upon the rights, liberties, and privileges of municipal corporations granted to them by charter."

From the point of view of medical administration, the proposals are fraught with great possibilities if not probabilities of friction and trouble. Administration is a thing difficult to define, but at least it can be said that it has two aspects—one is administering, the other is being administered. The subject is almost invariably discussed from the point of view of the minority who administer, and seldom from the point of view of the majority who are being administered; but the latter is a most important point of view, especially in purely medical matters. It must be remembered in this connexion that public health no longer concerns itself purely with the environment of communities, but has in recent years invaded the realms of personal hygiene in many directions—tuberculosis, venereal diseases, school medical service, and maternity and child welfare. In these departments the medical officers of local authorities are carrying out medical work in many respects indistinguishable from the work of the general practitioner of medicine. It is true that personal advice given by the former is called "preventive medicine," and precisely the same advice by the family doctor "curative medicine," but there is no difference—the public health official in these matters stands in the same close personal relationship to the person advised that the family doctor does. In this relationship his most important asset is his personality, and personality is a thing which cannot be administered. The public medical officer should be as free as possible to give the advice he thinks best without regard to the medical opinions of other medical officials. Further, it is notorious that "doctors differ," and it is a common belief amongst members of local authorities and others that many, if not all, medical officers are "faddists." This belief is supported by high official authority, which says that many medical officers "muddle on from hand to mouth, the victims of every passing whim or popular stunt."

It is probably given to few medical officers of health to distinguish with certainty between ephemeral fads and eternal truths, so that under any arrangements such as those suggested, in which the work of medical officers of health of boroughs and urban districts became subject to the supervision of county medical officers, there would be endless opportunities for difference of opinion leading to friction.

The principle involved is one which seems to me to be of fundamental importance to the British Medical Association, which stands for the honour and interests of the profession. Neither the honour nor the interests of the profession are served by any arrangements which detract from the freedom and independence of large numbers of its members.

From the non-county borough and urban district point of view, then, the proposed reforms are thoroughly objectionable. What are the alternatives?

The first alternative, and the one which seems to provide the most complete solution to the medical difficulties of local administration, is that put forward in the Memorandum of Evidence to be given on behalf of the British Medical Association before the Royal Commission on Local Government. This solution involves a radical revision of

the areas of local government, each of which should have as a centre a considerable town, associated with which would be such surrounding urban or rural areas as would most naturally or conveniently look to such town for its main hospital provision or as a focus of health administration. In each such area the local authority would administer all health services, including those now administered by the guardians and the Insurance Committees.

It is improbable that any such radical revision of areas would be undertaken even by the boldest reformer, so that something short of this ideal must satisfy us.

The council of the Association of Municipal Corporations puts forward for consideration—

"the suggestion that these transferred functions of the guardians should be performed by the council of a non-county borough in cases where that council are the local education authority for the purposes of elementary education and are also an authority under the Maternity and Child Welfare Act, 1918."

This suggestion implies that these councils retain their present health functions and status without the supervision of the county council. Anything less than this would be a calamity to municipal health administration in this country, which in many respects represents the most progressive and advanced health services to be seen anywhere.

I am aware that in the above short consideration of the subject I have not added anything new to views already expressed, nor have I gone into details. Consideration of details might only tend to obscure the main principle for which the boroughs and urban districts are fighting—namely, that they be allowed to carry on their good work with such additional powers and duties as Poor Law reform may impose upon them, but without supervision from the county councils, which is entirely unnecessary and undesirable.

#### IV.—ARTHUR L. BALY, M.A.CAMB., M.R.C.S., L.R.C.P., Chief Medical Officer, Lambeth Board of Guardians.

##### FROM THE POOR LAW MEDICAL OFFICER'S VIEWPOINT.

THERE is a great deal of confusion of thought in regard to Poor Law matters, and it is to be feared that as a consequence ill considered schemes may be passed through Parliament, which will make confusion worse confounded and lead to gross extravagance.

Sixteen years' experience as medical superintendent of a Poor Law hospital controlled by a board of guardians enables me to judge what can be done under the existing Poor Law, and as my work has brought me into contact with numerous other authorities at the present time engaged in doing small portions of medical relief, such as tuberculosis, mental deficiency, lunacy, war pensions, etc., I am in a position to express an opinion as to what is likely to happen if the work at present performed by boards of guardians is handed over to any one authority; or, still worse, divided between two or more authorities, none of whom is at present capable of dealing with the work which it is supposed to do completely and efficiently without the assistance of the existing boards of guardians. There is no doubt that if any of the proposals so far put forward are introduced without retaining the present Poor Law system controlled by a local authority in each area of a reasonable size, the result will be waste of public funds and, as far as medical relief is concerned, an even more chaotic state of affairs than at present exists.

It might be worth while, even at this late hour, to ask the question, What is it that the public desire? This question is best answered by quoting from the annual report of the United Hospital Fund for New York, 1924-25, wherein is described a scheme which is being introduced into that city which "will give the patient what he had in the days of the old family practitioner—a single source on which he can depend for his health."

This is undoubtedly an ideal to be aimed at, but in existing circumstances is impossible, and in any circumstances would take a prolonged period, possibly a quarter of a century, to develop. Such a scheme, as far as London

is concerned, would require a single authority in each area to deal with all forms of medical relief, and, for efficiency's sake, that area should be large enough to justify the necessary expenditure in order to provide all forms of medical relief in each area, but not so large as to cause the evils always associated with large central (especially medical) authorities. Such a scheme would require that in each area there should be a controlling or parent institution into which patients of all classes, including fever, mental, and all the other specialized branches of medicine, could be admitted, so as to abolish, as far as possible, the separate specialized institutions; and, to complete the scheme, all other institutions in that area, and all domiciliary treatment, should be subordinate to the staff of the parent institution.

How can this ideal be obtained? There is no doubt that the simplest method of attaining such an ideal is by modifying the existing Poor Laws in order to ensure that they will be properly administered.

The Poor Laws sanction the provision of every possible form of medical relief; in fact they not only sanction but require the guardians to provide whatever may be necessary to maintain all persons (who are destitute on account of sickness or insufficient means) in health. The standard of work performed by the guardians depends upon the character of the guardians and their officers. Is it past the wit of man to alter the electoral law and constitution of boards of guardians so as to ensure that they will carry out the real wishes of the people? I would suggest that the guardians should be in part elected and in part nominated; and further, that those unable to pay in full for the relief they receive should be disfranchised as far as their local vote is concerned.

Having established efficient boards of guardians it would then be possible to undo the harm caused in recent years by the creation of new and superfluous authorities for dealing with small portions of medical relief and to revert to a single authority in each area, so that the ideal which is being aimed at in New York—of abolishing specialized institutions and placing all classes of patients in charge of a single general staff, assisted by specialists—might be obtained, to the infinite advantage of all concerned, including the ratepayer.

Incidentally this will aid in the solution of the most serious problem connected with lunacy reform, which arises from the fact that certified mental cases have to be segregated in separate institutions known to the public as asylums. Under the scheme outlined it would not be necessary to transfer recoverable mental cases to asylums, but they would be treated in a general institution, or a block of a general institution set aside for the purpose, so that the stigma of certification in such cases would very soon die out, and ultimately the existing asylums would be handed over to the various local authorities and utilized as general institutions for all varieties of cases.

The Medical Centre which is being created in New York by the United Hospital Fund for that city has in fact been started by the amalgamation of a general hospital with several special hospitals, and, although all branches of medicine have not yet been included, it is important to note that a mental hospital has been included.

It must be admitted that an atmosphere has been created, as a result of which the public demand the abolition of the Poor Law; but there is no doubt whatever that, in making what might appear to be a drastic change, a prudent law-maker would abolish the boards of guardians and retain practically the whole of the Poor Law intact, and at the same time create a new and more satisfactory local body to administer that law; avoiding on the one hand the evils always associated with a large central medical authority, and, on the other, the transference of the guardians' duties to any existing local authority which has not in any way demonstrated its superiority to the existing guardians; and, ultimately, having set up a satisfactory local authority, take steps to hand over all questions of medical relief to the single local assistance authority.

The principles suggested in the Maclean report have been put into practice in regard to tuberculosis, the

domiciliary treatment being placed under the charge of the borough councils and the sanatorium treatment under the county councils. The guardians have ample evidence of the unsatisfactory results obtained, and it may be on this account that the proposals suggested in the recently issued White Paper have avoided the obvious pitfall of dividing the work between two authorities, and suggest the centralization of all Poor Law matters under the London County Council, to be assisted by local committees appointed for the purpose; but, there is nothing in the White Paper to suggest that these local committees are to have any more power than is possessed at the present time, in regard to education, by school managers, which power is so limited that the Government proposals amount to the creation of a large central authority. It may be possible to have an efficient central educational authority, but it is very doubtful if, in the opinion of the medical profession, an efficient central medical authority on such a large scale can be devised.

On the other hand, if it is intended to centralize all the work in London on the County Council solely for the purpose of abolishing the existing boundaries, and, without attempting to administer the whole of London from one centre, immediately to redivide the county into suitable areas and place them under the control of local committees with full powers to carry out their work in their own way, the County Council only retaining the supervisory powers at present exercised by the Ministry of Health, it is possible that a satisfactory solution may be evolved.

In view, however, of the cost of centralization, which some authorities seem to consider would be enormous, it might be more economical to reconstitute some of the existing boards of guardians controlling the larger areas and transfer to them all the various forms of medical relief at present under the control of other authorities, and in the meantime the smaller areas could either be absorbed or amalgamated. If the local committees or reconstituted boards of guardians are to be given effective power, there is little doubt that, for the sake of economy, they should be in part directly elected, as it is well known that bodies created by indirect election tend to become extravagant.

It must not be overlooked that not only do the Poor Laws sanction every form of medical relief, but they also require the guardians to demand payment for the relief given from those who receive it and from the liable relatives (adults being responsible for their parents and grandparents, and parents for their children and grandchildren), in accordance with their means after due inquiry. The Lambeth Guardians collect over £20,000 per annum by this means. Is it possible to imagine a local committee, subordinate to a central London authority, lacking any real power (like existing school managers) and not directly responsible to the electors, having sufficient interest to carry out the work of assessing these charges in a satisfactory manner? At present the cost per head per week in the Lambeth Hospital for everything, including interest on loans, is 35s. 4d. for a daily average of 1,360 inmates. Provision is made for the acutely sick of all classes, there being 1,000 beds staffed by trained nurses and probationers, and 600 for infirm and cripples, although a further 400 infirm cases are boarded out elsewhere, which makes the cost even more satisfactory. I venture to predict that the same work will certainly not cost less if administered by a central authority.

The public appear to be demanding two things: first, an alteration in the present system, and, secondly, an increase in the amount of medical work to be carried out by public assistance; and they should realize that both will lead to increased expenditure.

Lastly, there is a most undesirable tendency to amalgamate medical insurance and public assistance. The former should be on an economic basis, possibly assisted by the funds of voluntary charities, and if it is found necessary that any work should be performed by the public assistance authority on behalf of an insured person such work should be paid for out of the insurance funds. On the other hand, any public assistance not paid for in full should entail local disfranchisement.

## GENERAL DISCUSSION.

Dr. EUSTACE HILL (Durham) said the Memorandum of the British Medical Association and the readers of some of the opening papers had overlooked the necessity for unifying the public health services, which was the essence of the proposals of the Ministry of Health. The Memorandum, he considered, must have been drafted without full knowledge of public health administration in all its aspects. It was also inconsistent, inasmuch as it stated that county councils were totally lacking in the machinery for sanitary administration, yet in another paragraph it suggested that the health administration of the smaller rural areas should be handed over to them. It was interesting to note that while the Association of Municipal Corporations and other bodies were opposing the suggestion of the Minister of Health to give supervisory powers to county councils, this principle had been adopted in much recent legislation relating to public health. An instance of this was to be found in the law relating to control of the milk supply, whereby it is enacted that if in the opinion of the Minister of Health a local authority is in default in exercising its duties its powers may be transferred to the county council. This was the very type of legislation to which Dr. Garrow now took exception, yet so far as he was aware no serious objection had been offered by the local authorities concerned while the bill was under discussion. It appeared to be the opinion of some of the speakers that county councils would be found to be lacking in administrative capacity, but if they examined the personnel of such councils they would find that a large proportion of the members were also members of urban or rural councils. At present he considered that sanitary administration in this country was often most ineffective. There were many urban districts with populations of 1,000 or less, and on the other hand there were rural districts with large populations—in some cases exceeding 70,000—which were urban in character and rural only in name. Some system of unification was essential, and he would like to see the counties divided, for purposes of public health administration, into districts with a population of from 80,000 to 100,000, to each of which should be appointed a properly qualified and experienced whole-time medical officer of health, subject to the necessary supervision of the Ministry of Health and the county council. If that were done he would be quite prepared to recommend that much of the health administration of the county council, such as that which concerned tuberculosis, maternity and child welfare, etc., should be delegated to such district officers, who in respect of these delegated services would become assistant county medical officers.

Dr. D. C. KIRKHOPE (Tottenham) believed that public health administration should follow the lines indicated by evolution, which were in the direction of concentration on the individual. The medical officer of a small area, he thought, had the more intimate acquaintance with the population of his area and the circumstances in which they lived, so that their environmental and personal disabilities were generally known to him and as speedily as possible relieved. It was, in his opinion, the intimate relation with the individual family, rendered possible by the maternity and child welfare and school medical services, that had contributed most largely to the reduction in mortality and morbidity which was general throughout the country. The county area would be too large for the administration of such public health services, although the county might be the authority for the administration of large institutions, which could not be economically established by smaller authorities.

Dr. STELLA CHURCHILL (London County Council) said the existing scheme of public health administration in London was responsible for a great deal of overlapping. There was, for instance, the Children's Act of 1908, administered by the County Council with fourteen whole-time inspectors at a cost of approximately £5,000 a year, and the same children were also visited by the health visitors employed and paid by the various metropolitan boroughs. Contacts of infectious diseases in schools were dealt with at once by the local

medical officer of health, but the school medical officer only visited after a given number of cases had occurred in the same class. The actual work of inquiry into cases of surgical tuberculosis was done by the borough care committee, but clothes and other necessities were often provided by the board of guardians. The Metropolitan Asylums Board, which was really a Poor Law authority, provided nearly all the beds for tuberculous cases in London and all the accommodation for infectious diseases. County Council by-laws, she said, were not generally acceptable to the boroughs, but many of them were important from the public health point of view. She asked why each borough infirmary should not become the municipal hospital, with local control independent of the Metropolitan Asylums Board, which now attempted the colossal task of administering some 71,000 beds. She could not follow Dr. Baly in his suggestion of disfranchisement for everyone who accepted any service paid for by the Poor Law, and asked if he would demand the same penalty from a mother who availed herself of the maternity and child welfare service provided by the municipality, or from anyone who had to be isolated in a municipal isolation hospital.

Dr. G. H. PEARCE (Batley) agreed with Dr. Garrow's contention, and gave examples of the difficulties which would arise if non-county boroughs and the larger urban districts were placed under the administration of the county councils in respect of health services. He supported the Memorandum of the Association, and expressed the view that county councils could not carry on the work as well as it was being done at present by the larger non-county authorities.

Dr. H. SCURFIELD (Folkestone) quoted the cases of Essex and Hampshire as two instances in which counties were securing unification of public health services, and pointed out the differences in the methods adopted. Any satisfactory scheme must, in his opinion, include the formation of areas of sufficient size to justify the appointment of whole-time medical officers with local control by elected representatives. It had been stated that democracy was a failure. It might have failed in certain instances, but it was impossible now to contemplate the abandonment of its principles.

Professor F. E. WYNN (Sheffield) said he thought the differences of opinion which had been revealed within the ranks of the Association were more apparent than real. He did not think anyone seriously wanted to deprive large and highly organized urban districts of public health functions which they were performing satisfactorily. But there were rural areas in which neither the local authority nor the county council seemed to be equipped for dealing with practical sanitation, and it was essential that any reform should include provision for bringing the sanitation of such districts into line with that of the larger urban districts and county boroughs.

Dr. BRACKENBURY (Hornsey) said the Memorandum of the Association had been referred to as his Memorandum. It was true that he had been responsible for the drafting, but that had consisted merely of putting in consecutive order resolutions adopted by the Representative Body and the Council of the Association. There was nothing in that Memorandum that did not represent the considered policy of the Association, and he repudiated the suggestion that had been made that the Memorandum had been drafted without adequate knowledge of municipal administration. Both the Representative Body and the Council of the Association contained members thoroughly experienced in public health administration, and he himself had been for many years a member both of a county and of a borough authority. Dr. Brackenbury then explained in further detail the nature of the delegation of duties involved in the Memorandum, and stated that the Association was not opposed to the assumption of the public health functions of a local authority by the county council where it could be shown to the satisfaction of the Ministry of Health that the local authority was in default.

Dr. B. HILL (Selby) spoke from the point of view of the medical officer of health of a large combined urban and rural area. The whole question was, What was to be the health authority of the future? He was convinced that in the case of combined areas it was essential that all health duties should be retained by them, as otherwise it would be impossible to preserve the individual aspect of public health work, or to increase the interest taken in public health work by the local representatives. Neither of these objects would be attained by making the local medical officer of health merely an assistant to the county medical officer.

Dr. MIDDLETON MARTIN, replying on the discussion, said he had not questioned the administrative competence of boards of guardians or their officials. Unification of the public health services was essential, and there was no doubt that the Government intended to achieve it. He did not suggest that the county council should necessarily be the sole sanitary authority in the future, but they were bound to use their experience of the past to guide them in getting the best authority for the future, and he thought it would be found that in many cases the county would be the best unit of administration.

## LEGAL DEFINITION OF LIVE BIRTH.

BY

GODFREY CARTER, M.B.VICT., M.R.C.P.ED.,  
D.P.H.LOND.,

Lecturer on Forensic Medicine, University of Sheffield;  
Senior Police Surgeon, Sheffield City Police.

THE subject of puerperal morbidity has of late been receiving some of the increased attention to which it is justly entitled. It is one having interests in varied directions, and is destined, without doubt, to conserve a considerable amount of infant life; but there is one matter coming clearly within its purview which seems to have almost escaped attention, yet its importance justifies serious consideration. I refer to the large number of babies who are criminally interfered with during or immediately after birth because their advent is not desired, and because, also, it has become known that detection and punishment rarely follow—I was going to say, "follow this crime of infanticide"; but in English law, as it stands to-day, it is no crime, nor even a misdemeanour, to kill a child during the act of being born. This is a fact which, although plainly stated in all our works on forensic medicine, seems to have escaped the attention of the medical profession as a whole, and failed to be seriously noted by medical jurists. The consequence is that throughout the country, and certainly in our cities, an appreciable number of full-term healthy infants lose their lives.

I have been asked, What is the legal definition of live birth? The answer gives rise to surprise: that there is no statutory definition of live birth in English law, only a formula accepted by what is known as "common law."

The rulings laid down by judges in the past, and now by general consent accepted in the courts, are to this effect: That in order to be born alive a child must show some signs of independent existence *after every portion of its body is free from the mother's parts*. As Dixon Mann says in his work: "In order that murder can be perpetrated, the victim must have had a separate existence. The killing of a child in the act of birth, and before it is fully born, is not an offence by the present law."

In the legal sense a partially born infant has not a separate existence, although it may breathe and has consequently acquired the power of maintaining life as a distinct individual. It must be "under the King's peace."

Since infanticide is usually committed with the object of concealing the occurrence of birth, the deed is done in secret, and in most instances without the connivance of a second person. The burden of proof of live birth therefore falls on the medical witness. How is he to swear that when certain injuries found upon the body, and which put an end to physiological life, were inflicted, every part of the child's body was free from the mother's parts? He cannot; only an eye-witness could so testify. The bed-rock fallacy of

the legal definition lies in the fatal inaccuracy in that the law assumes all children to be born dead unless satisfactory evidence is produced to the contrary. Could anything be further removed from the truth, or act as a greater deterrent to the course of justice? What is the rate of infant morbidity from all causes, and taken in the mass of attended and unattended births? Little more than one in a thousand. Evidence required of an independent existence after the complete extrusion of the child is a fallacy, and probably had its inception in past ignorance, when it was believed that a foetus drew its blood direct from the mother's circulation. We know that the foetus has its own independent circulation, anatomically separate from the mother's, from the time of the establishment of foetal heart beats. Therefore the child has an independent existence when in the mother's womb, drawing its oxygen through a limiting membrane, as later in the lungs.

The living child recovered from the body of the dead mother by Caesarean section is carrying on with the reserve oxygen contained in its own blood. To rule that a full-term well formed child, showing no signs of disease, and obviously having been physiologically alive at or about the time of birth, was born dead, because no witness is produced who will testify to some obvious sign of life, after full delivery, and before certain injuries were inflicted, or criminal interference had taken place, is travesty, and an encouragement to the wrongdoer.

Not all the judges, be it said, have held to the present accepted definition.

Lord Young, at the High Court of Perth in 1892, in charging the jury in a case of alleged infanticide, said:

"If the child was killed and the prisoner was to blame for its death she is guilty of culpable homicide. If she went on from the conception to the birth of the child, desiring to hide her shame, and refrained from calling assistance when assistance was at hand and took upon herself to assist herself, and in the agony of childbirth grasped the throat of the child, with the result of causing its death, I cannot say that she is not blameworthy, or that her blameworthiness does not amount to culpable homicide. If you think that blame does attach to her, then culpable homicide is the name for that blame, resulting as it did in the death of a child which had both cried and breathed. It does not matter in the least, so far as the criminality of the accused is concerned, if the injuries were inflicted when the child was partly in its mother's body."

Again, Mr. Justice Wright, in the case of *Rex v. Pritchard*, for alleged infanticide, tried at the Shrewsbury Assizes in 1901, said regarding live birth:

"That the true test of separate existence in the theory of the law (whatever it might be in medical science) is the answer to the question whether the child is carrying on its being without the help of the mother's circulation."

Commenting upon this Glaister says in his work on forensic medicine:

"This last legal pronouncement levels up the difference in definition between the law and medicine, inasmuch as it is well known that a child may not only breathe before complete birth, but cry audibly before its body is completely born from the mother's parts, and that it can only do this by virtue of the independent exercise of its own organs, and quite apart from the aid of the circulation of the mother."

"If this decision could be accepted as the uniform expression of the law by judges, the medical profession would be called to accept it as being not only in accordance with physiological fact, but as tending to repress the crime of child murder, which has in many cases gone unpunished because of other interpretations of the law by other judges."

I have been deeply impressed with a certain fact in my own mortuary experience, and it is this: that in nearly every *post-mortem* examination I have made upon the bodies of well formed mature newly born children recovered from cellars, closets, middens, linen baskets, and servants' boxes, or found on canal or river banks, there was evidence of full respiration, often associated with air drawn into the stomach, also signs of asphyxia, and in some cases ligatures were present round the neck. Obviously they had had an independent existence when their lives were deliberately extinguished, for complete aeration and expansion of the lungs does not take place prior to complete extrusion of the body from the mother. Compression of the chest during birth prevents it. But few, if any, convictions were obtained.

In the preliminary inquiries the question is asked, "Was the child legally born alive?" The law assumes

that if not proved to have been born alive, the child never lived, and if it never lived it could not be killed. So matters stand at the present time, and I feel that there is urgent need of a change, and that legal statutes should be instituted which would conform to physiological truth, as well as to common-sense appreciation of facts as proved by medical findings.

In the absence of wedlock the infant mortality at birth is considerably above the average. This is a significant fact; and also that such births frequently take place in secrecy, and the bodies of the children are secretly disposed of, their survival not being desired.

Even amongst the very poor, in wedded life, and where skilled attention is not always forthcoming, deaths from asphyxia are rare.

Nature favours the child at the expense of the mother in order to carry on the race, and if it is desired that children should survive their birth they usually do survive. I will now refer to another aspect of this subject. Although the facts point to the contrary, in some cases where a child was unmistakably born alive, and where the cause of death has been asphyxia, "inattention at birth" is the finding. This "inattention" is in most cases, I am satisfied, criminal. A gross act is usually required to produce death, either deliberate prevention of breathing or abandonment and exposure. Glaister says:

"The inference is, that where a woman conceals her condition during the whole course of her pregnancy, makes no preparation for and calls for no assistance at the time of her delivery, she is conniving at the death of her child, by omitting to do those things which a woman in ordinary circumstances would not fail to do. But at the same time the law does not place upon the woman the burden of proving that her child was stillborn. It puts upon the prosecutor the burden of proving that the child was born alive, and demands of him a proof of the most difficult kind to establish, because of the secret character of the circumstances in which the birth takes place. To our mind this is quite illogical. The older law placed this duty of proving that the child was stillborn upon the mother."

The subject has been considered by two Parliamentary Commissions. The first, the Capital Punishment Commission of 1865, arrived at the opinion that

"an Act should be passed making it an offence punishable with penal servitude or imprisonment unlawfully and maliciously to inflict grievous bodily harm or serious injury upon a child during its birth or within seven days afterwards. No proof that the child was completely born alive should be required."

The second Commission in the Draft Code proposed that

"every woman shall be guilty of an indictable offence who, being with child, and being about to be delivered, with intent that the child shall not live, neglects to provide reasonable assistance in her delivery, if the child dies either just before, or during, or shortly after birth, unless she proves that such death was not caused either by such neglect or by any wrongful act to which she was party."

As Professor Glaister adds: "It is highly desirable that such should become law as soon as possible if the crime of child murder is to be successfully repressed."

To put my views in concrete form I would urge—

(1) That any child born at a viable period of development should be deemed to have been born alive unless satisfactory proof be forthcoming to the contrary.

(2) The adoption of the recommendations of the two Parliamentary Commissions as just stated.

It would be my earnest desire that these provisions should be incorporated in a new Act of Parliament and become law. There is nothing in them which could inflict injustice or hardship upon any innocent or well-meaning person. It would also give statutory law in place of loose custom. Its influence would do much to prevent those actions and lines of conduct which at present cause the sacrifice of many newly born children, and in its operation it would do another thing—it would force the accused person to give evidence in the witness-box, and state how it came about that the child did not survive. The witness would then be liable to be cross-examined by the prosecution, and the truth or otherwise of the evidence considered. If she did not volunteer to speak on oath in her defence this circumstance would tell heavily against her, as it does in all criminal charges.

I do not think anyone can be satisfied with the present state of the law concerning the definition of what constitutes live birth. But the matter seems to have failed

to arouse the interest it deserves, and I hope it is only necessary to call fresh attention to the facts to ensure that a proper remedy will be forthcoming.

#### LEGAL DEFINITION OF LIVE BIRTH.

Following Dr. Godfrey Carter's paper, the CHAIRMAN proposed, and Dr. LEWIS-LLOYD seconded, the following resolution, which was carried unanimously:

That the Council of the Association be requested to approach the Government with a view to securing legislation to protect the unborn child against intentional violence until all parts of it are completely born—that is, during its passage from the mother's body.

#### COMMENTS AND PRACTICAL SUGGESTIONS ON CIRCULAR 426 (CANCER).

BY

JOHN BROWN, M.D., D.P.H.,

Blackpool.

My study of cancer began when I was a student in Cornwall in 1868. The first case was a married woman without children who had chronic cancer of the breast. Two years afterwards I left the town and lost sight of her, but on returning to the town in 1924 I found from her tombstone that she had died in 1876, aged 76 years. This woman had lived eight years without operation; the exact cause of death I could not ascertain, but it was probably "natural decay." My second case was one of successful operation, without recurrence, for cancer of the tongue in a woman, and I recently heard from a relative that the cancer was removed in 1875 or 1876 by Sir T. H. Butlin. The patient returned to Australia and made an excellent recovery. She died only two years ago at the advanced age of 87, from senile decay.

These two cases are very suggestive of the value of following up patients. I cannot too strongly urge the adoption of this procedure in all cases, with a special inquiry in regard to such matters as etiology, treatment by operation, dietary, x rays, and medicines, on the lines of the questionnaire which I submitted to the Ministry of Health about three years ago or on the lines suggested by Dr. Hoffman. In all certified deaths of cancer in this and in all civilized countries which have State medical service, each death should be followed up by the "short questionnaire"; any special feature can be studied later. The importance of this has never been fully realized, and therefore I make this a strong plea.

One of the most important fields for the incidence of cancer mortality is the study of the Registrar-General's report for England and Wales for the years 1918, 1919, and 1920, and the 1919 reports for Scotland and Ireland. I spent a vast amount of time in going through the cancer statistics from the standpoints of the counties, boroughs, county boroughs, metropolitan boroughs, Greater London, cities, universities, industrial towns, and health resorts. I also paid attention to the sites of cancer in the body, the occupational and age groups, and social classes.

The statistics indicate that there are many fields for practical study of many etiological factors of cancer. The cancer death rate in all great centres of the coal industry suggests that the low figure for colliers and their wives is largely due to their active and strenuous life and their plain but efficient dietary. In 1918 I investigated specially the cancer mortality of colliers in the chief centres. The death rate for colliers in Rhondda was 1 in 26.8; in Wigan 1 in 23; and in Northumberland 1 in 22.5. Contrast with this the residential, seaside, and agricultural districts. In Kensington the rate was 1 in 11.8; in Hampstead, Blackpool, Southport, Bath, Hastings, and Oxford 1 in 10; and in Cambridge 1 in 11.

My views on the biological range were those set forth in textbooks and the *Encyclopaedia Britannica*—that all vertebrates, including fish, had cancer, and also that this condition occurred in trees and plants. The evidence in regard to cancer in fish and trees is not, however, conclusive.

Circular 426 was issued in August, 1923. At the end of three years cancer has greatly increased; various circulars and leaflets have been issued, but we have not yet provided efficient free clinics for the early diagnosis of cancer.

In the House of Commons, on July 13th last, Mr. Neville

Chamberlain said that there were 50,000 cancer deaths in 1925. This meant that out of every seven persons who have reached the age of 30 years one will die of cancer. He was sure of nothing more certain than that a cure was coming. In the meantime, the most important thing of all was to get early diagnosis, by which life could be substantially prolonged. Similarly the Duke of York and Sir Berkeley Moynihan had spoken in optimistic terms of an early cure. Such statements ought to arouse interest and cause practical steps to be taken to teach the laity the early history of all growths. The preliminaries of cancer in the breast, skin, and mouth can be easily detected before they have become definitely cancerous, and the disease be thus prevented. In the early stages many patients would be cured without operation. We have much to learn from America in this respect, and we ought to adopt any and every successful method employed in America. I have followed what is being done in other countries. As the result of extensive study of the question in this country, and of the early diagnosis and treatment, I believe that there is no specific germ, there is no specific treatment, and in the early stages there is rarely need for operation, because Nature is always on the side of the host. What is wanted is the most careful study of each case, and of all the excretions and secretions; attempts must then be made to restore these to the normal by dietary, maintaining a hopeful outlook, physical exercise, and securing healthy oxygenation. Many patients will get well. Free consultation clinics should be provided for all persons not under medical treatment. I have information from Detroit and Harvard which proves that one of the most practical methods of treatment is to educate the people. Dr. Fraser and others believe that cancerphobia will not follow. We can depend on general practitioners to support the State in this and every other method to prevent cancer, while the lay press will also help. Circular 426 embodies some of the suggestions from my paper on cancer, "Suggestions and conclusions relative to the prevention of cancer," which was read at the Scarborough Congress of the Royal Institute of Public Health in 1923. On page 10 of Circular 426 there is one practical suggestion—namely, that local facilities for clinical and pathological examinations should be established; after three years I fail to find that free clinics have been started. The annual report 1921-22 of Harvard University states that 1,062 cases of cancer were treated; of these cases 668 were growths that can and ought to be diagnosed in the precancerous and early stages of cancer—namely, breast 83, buccal cavity 231, skin 354. The report further states that "since the adoption of the out-patient clinics early diagnosis is made of the suspicious growths and fewer cases in the incurable form are now seen."

We must teach persons, especially those over 35, that cancer in the three sites named ought to be diagnosed when the growths are simple overgrowths of the epithelial tissues, and that the three precancerous stages are curable.

The success that has attended the institution of free clinics for tuberculosis and venereal diseases is strong evidence that similar success will result in the case of the greatest scourge of the whole race. Free clinics should be under the Ministry of Health, and the health authorities should make the arrangements, preferably co-operating with the hospitals, universities, and colleges, so that free examination and advice be open to all. All women over 30 and men over 35 who have suspicious growths or other symptoms indicative of cancer should most certainly avail themselves of these free consultations.

It has been urged that suspicious growths and cancers should be made notifiable; the public is not ready for this, but I suggest that voluntary notification of such cases should be encouraged, when the patient's consent can be obtained. In this way early diagnosis would be obtained, many cures result, and much valuable information be obtained.

A few days ago one of my supporters, in reply to my appeal for assistance from his special branch, replied that he was in sympathy with my views, and that what was needed in the cancer problem was an "ultra Pasteur." The future success will result from the work of laymen of the Pasteur type rather than from medical practitioners. Our knowledge of the new sciences is as yet far too meagre for such a problem as this.

## Memoranda:

## MEDICAL, SURGICAL, OBSTETRICAL.

## TRANSVERSE PRESENTATION WITH NORMAL PELVIS AND NORMAL CHILD.

As transverse presentations are fairly rare the following case may prove of interest:

I was called to see an Assamese tea-picker, said to have been in difficult labour for the previous twelve hours; it is rare to be asked to attend these women because they resent, for caste reasons, a man's presence, and are also very mistrustful of the methods of Western medicine. I found the patient anxious, with a clammy skin, a temperature of 98.2°, pulse 120 and thready, and rapid respiration. Further examination showed an abnormally shaped abdomen, a distended bladder, the uterus hard and slightly tender, and the foetal head in the right iliac fossa. Other foetal parts were not well felt as the uterus was strongly contracted. The child was dead and its right hand was prolapsed outside the vulva.

**Previous History.**—The patient had had ten previous normal deliveries, seven of the children being still alive, while the other three lived for a few years each. There was no previous history of abnormality.

**Present History.**—Labour had commenced at 1 a.m.; one hour later the membranes ruptured and a hand prolapsed. Labour pains had been frequent and strong but ineffective in expelling the foetus. The patient had had retention of urine for five days. During pregnancy native midwives had several times attempted to procure an abortion as the child was not wanted; this had never been done in any of her previous pregnancies.

**Treatment.**—The patient was removed to the Estate Hospital. The bladder was catheterized and emptied of 18 oz. of high-coloured acid urine. The os was three-quarters dilated. Attempts to replace the hand and to perform external version failed as the uterus was tightly contracted round the child and all the liquor amnii had drained away several hours before. Uterine contractions were not frequent, but lasted long and were very strong when they did occur. The pulse rate was now increasing. The patient was anaesthetized lightly and I attempted to decapitate the dead child, but failed as the os was tightly contracted round the shoulder girdle, thus preventing the introduction of an instrument. I amputated the prolapsed right arm at the shoulder and was then able to push up the child and get my hand into the uterus, when I seized the child's right foot, performed internal version, and delivered the child as a breech. The os quickly closed round the child's neck, preventing birth of the head. After several methods of extraction had been tried without result I decapitated the child with scissors and proceeded to deliver the retained head. Owing to the small size of the os forceps could not be used, and an attempt at perforation or cephalotripsy would have been dangerous. The patient was deeply anaesthetized, and by prolonged and forcible manual pressure I managed to dilate the os a little more and so was able to place my finger in the child's mouth and pull; unfortunately the mental symphysis gave way. I then put my finger well down the child's throat and, with suprapubic pressure as an adjunct to strong steady traction, I was successful in withdrawing the head. The placenta and membranes followed completely one and a half hours later. A hypodermic injection of pituitrin was given and the pulse soon improved. There was no alarming after-symptom, and the temperature was 99.2° after delivery of the placenta. The manipulations lasted three and a half hours. The next day there was a slight rise of temperature (100.4°), which soon subsided after a hot douche. The puerperium was normal, and the patient is now quite well and working.

Interesting features of the case are that the patient had had ten previous normal deliveries and that the child was normal in size and not deformed in any way; the pelvic measurements of the mother were normal, and no tumours, placenta praevia, uterine obliquity, or hydramnios were present to account for the malposition. Doubtless the manipulations of the native abortionists were responsible for the transverse presentation.

EDMUND BURKE, L.R.C.P., L.R.C.S.Ed.

Margabhai Medical Association, Dimakusi, Assam.

## ADRENALINE IN CARDIAC ARREST.

A MALE infant, aged 6 months, was being anaesthetized for an operation for inguinal hernia when respiration suddenly ceased. He became pale and flaccid, and the heart stopped; he was apparently dead. I injected 5 minims of 1 in 1,000 adrenaline solution into the heart, and in less than a minute the heart began again and the baby was carried out of the theatre crying loudly, much to the relief of all present.

This happened over a year ago, but it is interesting in connexion with the discussion on heart massage.

JOHN LIVINGSTON, M.D.Durh., F.R.C.S.Ed.,

Senior, Honorary Surgeon, North Lonsdale Hospital.

## Reviews.

## CAMERON'S "DISEASES OF CHILDREN."

*Diseases of Children*,<sup>1</sup> by Dr. H. C. CAMERON, forms one of the series of Oxford Medical Handbooks, and follows the plan of this series in giving a general survey of the subject, with emphasis on certain aspects. Dr. Cameron defines the object of his book in a neat sentence, as not "a set performance, but only to sound a few chords here and there sufficient to illustrate the astonishing range and tone of the instrument." The topics he has selected for discussion deal mainly with the period of infancy, and in an introductory chapter he shows their interrelation. They are nearly all included in the four great factors of inheritance, environment, food, and infection. The working of these factors is followed out in such problems as difficult cases of breast-feeding, the influence of the infant mind upon general health and digestion, the frequency and significance of catarrhal processes in infancy, certain types of inherited diathesis and their manifestations in childhood, the reaction of infants and children to the mental tone of mothers and nurses, and the interaction of digestion, infection, and purely mental influences in the nutritive disorders of infants. These problems are important, indeed fundamental, and have given rise to much discussion and not a little confusion; they are handled in this little book in an admirably clear and sensible way. These qualities are well seen in the final and longest chapter, which is on diet. The difficult subject of artificial feeding is of set purpose kept to the last, and after the other factors of inherited constitution, of personal management, and of trivial or obscure infection have been discussed. This unusual but really rational order of treatment undoubtedly facilitates the understanding of the problems of dieting in the dyspepsias of infancy; and the British reader is almost unawares persuaded into the German classification of nutritional disorders, *ex constitutione*, *ex infectione*, *et ex alimentatione*, though little or nothing is heard of the horrid German vocabulary of special terms. The clinical features, even in dyspeptic infants, are admirably described, and the brief accounts of treatment are most helpful.

Dr. Cameron has some friendly criticisms to make on the methods and policy of child welfare centres, but pays a high tribute to the results already accomplished by them. He also makes an earnest appeal for more consideration and more teaching of the subject of diseases of children in the medical curriculum.

As a well informed, wise, and very pleasantly written discussion of the subject in some of its general and important aspects, Dr. Cameron's little book can be warmly recommended to those engaged in general practice or in special work among children. The matter of the book is so good that the publishers might have allowed a larger page and an ampler margin, but both in what is said and in the manner of saying it the book is *multum in parvo*.

## PARASITIC PROTOZOA.

*The Manual of the Parasitic Protozoa of Man*,<sup>2</sup> published recently by Colonel CRAIG, M.D., of the Medical Corps of the United States Army, covers a field considerably wider than is indicated in the title, in that some free-living species and also closely related forms in the lower animals are dealt with. The author's experience enables him to speak authoritatively upon the subject, and his work, the embodied results of that experience, will doubtless be extensively read and appreciated, as it certainly deserves to be.

After an introductory chapter on the classification, structure, physiology, and reproduction of protozoa and

<sup>1</sup> *Diseases of Children*. By Hector Charles Cameron, M.A., M.D., Cantab., F.R.C.P.Lond. Oxford Medical Publications. Oxford Medical Handbook. London: H. Milford, Oxford University Press, 1926. (Fcap. 8vo, pp. ix+193. 5s. net.)

<sup>2</sup> *A Manual of the Parasitic Protozoa of Man*. By Charles T. Craig, M.D., M.A. (Hon.), Lieutenant-Colonel, Medical Corps, U.S. Army. D.S.M. London: J. P. Lippincott Company. 1926. (Med. 8vo. pp. viii+593. 5s. net.)

the meaning of the terms "parasite" and "parasitism," there follow four chapters on the amoebae, of which, naturally, *Entamoeba histolytica* takes the foremost place. The parasitic amoebae are fully described, but British workers will probably think that undue prominence has been given to species doubtfully amoebic, and more doubtfully parasitic. It is only fair, however, to say that the author is most careful to give the arguments for and against, and, where he has not actually himself worked at the organism, prefers to leave the evidence to individual judgement rather than to express his own opinion as to validity. Among these we may mention, as an example, *Councilmanella lajeuni*, Kofoid and Swezy, 1921. Another, by name *Karyamoeba falcata*, is "characterized by one, or rarely more, blunt pseudopodia, hyaline in appearance." Protozoologists will be the first to own that it is not very satisfactory to diagnose an amoeba and create a new genus on such a characteristic. Mere mention of the names would suffice for most of the doubtful parasites.

Flagellata infecting man occupy six chapters, two being devoted to the intestinal species and four to blood and tissue flagellates. Malarial parasites have three chapters, the coccidia, sarcosporidia, and ciliata one each. In each case the synonyms are given, with their dates of bestowal, their morphology, geographical distribution, life-histories, including, of course, some account of their vectors and modes of transmission, their pathology, diagnosis, and prevention—in fact, all that any student of the subject is likely to need, and, but for the fact that treatment of the diseases set up is not included, any medical practitioner. The subject of treatment, other than prophylactic, was not included in the author's aim. Another intentional omission is the spirochaetes, and, *a fortiori*, leptospirae, as these are now considered by the best authorities to be rather bacterial than protozoal.

Colonel Craig discusses in clear language points which are doubtful, states the evidence fairly and holds the balance even, and, when he expresses an opinion, this is always based on actual examination and experience, and not on personal predilection from a mere reading of the literature. The chapters on malaria are interesting. The author makes a distinction between *Plasmodium falciparum* and *P. falciparum quotidianum* (the *P. immaculatum* of Schaudinn) on the grounds that these are distinguishable morphologically, that they differ in the times of their human life-cycle, and produce characteristic febrile paroxysms. His discussion of the question is good, and will command respect in that he gives due weight to the views of those who maintain that there is but one species of aestival-autumnal parasite. An account is also given of a subspecies of *P. vivax*—namely, *P. vivax minutum*—which, first described by the author in 1900, was rediscovered and named by Emin fourteen years later. It is regarded as the same as *P. ovale* described by Stephens in 1922.

The work is well produced, easy and pleasant to read (although "autopsy" is used as a verb, and *ipecaquanha* is curtailed of its last three syllables), the illustrations are ample and clear, misprints are almost absent, and the author is to be congratulated on the excellent manner in which he has performed his self-allotted task.

#### ULTRA-VIOLET THERAPY.

THE little book by Messrs. T. CLYDE MCKENZIE and A. A. KING is rightly called *Practical Ultra-Violet Light Therapy*,<sup>3</sup> for with the exception of the preliminary chapters on electricity and generalities (which might almost be omitted) it deals entirely with the authors' own work. They appear to have used almost exclusively mercury vapour lamps of atmospheric type, for which they claim many advantages over the vacuum lamps which are in more general use. The atmospheric type of lamp is more robust, has a longer life, and is much safer to use, as it can be swung and moved about without danger of fracture by

the mercury "hammer." It is, however, somewhat more expensive than the vacuum lamp. The lamps used by the authors are fully described, and detailed directions are given for their employment; no others are mentioned, and consequently the book avoids giving the impression produced by certain other works on the same subject that it is compiled from a number of trade catalogues.

A strong point in favour of the volume is that in it a real attempt is made to place ultra-violet therapy on a less empirical footing than it hitherto occupied. Good methods, both of measuring the intensity of ultra-violet radiation yielded by a lamp and also of testing the sensitiveness of a patient before treatment, are given. The power of the lamp is tested by its ability to decompose carbon tetrachloride, a test which is justified by the fact that the rays most active in this respect are also most active physiologically. The decomposition of carbon tetrachloride liberates chlorine, which can be either titrated accurately by determining the amount of iodine liberated from a standard solution of potassium iodide, or more roughly by comparison of the tint of solution produced when a drop of 10 per cent. solution of potassium iodide is added to the irradiated carbon tetrachloride with a standard tint of known value, previously prepared. In either case it should not be beyond the capacity of any medical man to carry out the test. The sensitiveness of the patient is tested by exposing spots on the forearm to the rays at varying distances from the lamp and observing the reaction produced. A large portion of the book consists of a description of the methods of using ultra-violet light for different clinical conditions. We are glad to notice that full directions are given for its application in each. Here again there is an improvement on other works on the same subject; often the directions have been extremely vague.

We need hardly say that the authors are enthusiasts, and apparently there is hardly any condition for which they fail to recommend ultra-violet light. No doubt the field of application is very wide, but scientifically we think that the clinical section would be more valuable if fewer different conditions had been treated but larger numbers of cases in each category had been collected. On the other hand, the authors cannot be blamed for taking on such cases as presented themselves, and we must thank them for giving a clear account of their work. They have produced the most helpful book on their subject we have yet seen in English, and all who are interested in light treatment (an increasingly large number) should read it with care. They are sure to learn something from it.

#### DISEASES OF THE SKIN.

DR. RICHARD SUTTON in the sixth edition<sup>4</sup> of his well known textbook on *Diseases of the Skin* has included a large part of the matter of the previous edition with much that is new and valuable. Those who are familiar with this work, both in this country and in America, must admire among other things the clearness and excellence of the illustrations. It is no easy matter to reproduce with anything approaching accuracy the changes, often minute, in the skin when altered by disease. The chapter on general etiology and pathology seems to us to be especially valuable, for it contains in clear summary form the more important of the modern theories, and the application of those theories to dermatology, especially the effects of allergy and anaphylaxis. The author comments in the preface on the voluminous literature on syphilis in its various phases. This statement applies with special force to the use of bismuth compounds, which are, however, only shortly referred to under the treatment of syphilis, although fuller consideration is given to them in the early chapter on internal treatment.

The merits of Dr. Sutton's book have been adverted to in reviews of the previous editions. The fact that a sixth has been called for is in itself evidence of the continued popularity and usefulness of this standard work.

<sup>3</sup> *Practical Ultra-Violet Light Therapy*. By T. Clyde McKenzie, M.B., Ch.B., and A. A. King. With an Introduction by Sir John Robertson, O.B.E., C.M.G. London: Ernest Benn, Ltd. 1925. (Demy 8vo, pp. 103; 19 figures. 6s. net.)

<sup>4</sup> *Diseases of the Skin*. By Richard L. Sutton, M.D., LL.D., F.R.S. Edin. Sixth edition, revised and enlarged. London: H. Kimpton. 1925. (Double roy. 16mo, pp. 1305; 147 figures, 11 plates. 52s. 6d. net.)

## THE JOURNAL OF PHYSIOLOGY.

The *Journal of Physiology*<sup>3</sup> is now appearing with so much regularity that the fourth number of the new volume has been published before we have had an opportunity of referring to some of the papers in earlier numbers. Two of these—one by Anrep and Segall, and the other by Daly and Verney—deal with the heart rate and the circulation (Vol. lxi, No. 2, pp. 215 and 268). These observers have been able so to arrange their experimental conditions that they have had a circulation passing through the heart independent of a second circulation passing through the head and brain. Thus they have been able to show that the Marey reflex, by which a slowing of the heart is brought about, can be aroused by an increase of the aortic pressure and by an increase of the pressure of the blood flowing through the head. This reflex, therefore, depends on the conditions in the brain centres as well as on the stimulation of the peripheral ends of the afferent fibres in the heart. These afferent fibres, they were able to show, run almost entirely in the vagus. Anrep and Segall determined further that the central regulation implied, not only activity of the vagal centres, but also inhibition of the sympathetic centres. Thus there is a reciprocal relation between the inhibitor and accelerator mechanism of the heart. When the heart is released from the control of the nervous system it responds to an increased output by altering the length of its muscle fibres and thus increasing its contractile power, the rate remaining constant. If the nervous mechanism is in control it then responds to an increased output by increasing its rate. This, which is known as the "Bainbridge reflex," is now shown to be beyond all doubt a true reflex depending, like the Marey reflex, on the afferent fibres in the vagus.

Three other papers deal with the response of the cardiac muscle to changes in the fluid medium bathing the muscle tissues. When the concentration of the salts in this medium altered certain differences in the response occurred. For instance, when the medium was made more acid or alkaline the rate of conduction was diminished. When the potassium in the fluid medium was increased the conduction was impaired; when the calcium was diminished the conduction was unaltered, but the mechanical response was affected. An investigation by Gremels and Starling (ibid., p. 297) showed that an increase in the carbon dioxide breathed brought about an increase in the size of the heart, and that this increase affected both the diastolic and the systolic volume of the heart. Acids had the same effect, but produced the increase in volume more slowly. This is probably due to the greater and more rapid diffusibility of the gas. The converse of the increase of carbon dioxide was interesting, for the effect of diminution of the oxygen content of the blood did not manifest itself until the saturation fell to less than 40 per cent. of normal.

Another paper published in an earlier number may here be noticed; it is by J. Mellanby and A. St. G. Huggett, who claim to have shown that secretin exists in considerable quantity in the upper two-thirds of the small intestine in a preformed state, and that there is no evidence for the existence of a prosecretin. The process of the formation of secretin goes on independently of the acid chyme, and perfect pancreatic digestion may exist in the presence of achlorhydria.

In another paper, published in a subsequent number. Professor J. Mellanby states that the introduction of bile of an adequate reaction into the duodenum of a cat causes a copious secretion of pancreatic juice. The active substance was cholic acid, but its effect was profoundly modified by its association with the bile salts, and the presence of mucin. The optimum reaction of bile varied with the state of digestion. The duration of pancreatic secretion after the injection of bile into the duodenum is determined mainly by the distribution of secretin in the intestinal mucosa, which is the immediate stimulus for the secretion of pancreatic juice. The facts are held to afford a basis for the appreciation of the severe digestive disturbances which occur in catarrhal jaundice.

<sup>3</sup> *Journal of Physiology*. Cambridge University Press. Price 12s. 6d. net each. The *Journal* is the organ of the Physiological Society, and is supplied free to members of that Society.

## NOTES ON BOOKS.

The surgical examinee essaying the pass examinations will find his subject well abstracted in Mr. C. P. G. WAKELEY's *Aids to Surgical Diagnosis*.<sup>4</sup> So long as there are students and examinations the demand for these digests to bolster up the frailties of students will continue. The intense desire for knowledge in the few weeks before the examination, which should have been acquired during those pleasant months which have been allowed to pass, renders the call for "aids" perennial. In many cases it is the "refugium peccatorum," and a few will emerge triumphant, with an eternal blessing on "aids," and a shining example to a host of less fortunate brethren. Analysed critically they are a snare and delusion. Their instruction is superficial and fleeting. Abstracts, to be of any permanent value to the student, should be made from his own clinical and pathological observations with the help of the larger textbooks. He makes these in a manner best suited to his own way of remembering, which is not always the same as the digest of another mind. Mr. Wakeley's little book will be found to give short and concise information on the subjects he has undertaken, and any criticism would be directed to the form in which he has presented it.

A manual of practical work in bacteriology and serology for students has been prepared by Drs. J. F. NORRIS and I. S. FALK, assistant professors of bacteriology in the University of Chicago, under the title of *Laboratory Outlines in Bacteriology and Immunology*.<sup>5</sup> The time required to complete the series of experiments detailed is estimated at one year, and it is presumed that the book will be used only under the direction of a competent instructor. The manual includes exercises in the preparation of media, the microscopical examination of various organisms, the Wassermann, flocculation, and colloidal gold tests, the examination of water and milk, vaccine preparation, and the production of diphtheria and other toxins and anti-toxins, together with experiments on animals.

The second edition of *Systematic Case-Taking*, by Dr. H. L. MCKISACK of Belfast, appears under the title of *Aids to Case-Taking*,<sup>6</sup> and is included by the publishers in their "Students' Aids" series. The present edition has been revised, and although some of the sections appear to be hardly adequate, yet the book can fairly claim to be a comprehensive collection of methods of examination suitable for the hospital ward or the consulting room of the general practitioner.

*Goldfish Culture for Amateurs*,<sup>7</sup> by A. E. HODGE and ARTHUR DERHAM, is a simple and comprehensive book dealing with the breeding and rearing of goldfish in aquariums and ponds. The book is well illustrated with numerous photographs and drawings, and the information is thoroughly practical.

<sup>4</sup> *Aids to Surgical Diagnosis*. By Cecil P. G. Wakeley, F.R.C.S. London: Baillière, Tindall and Cox. 1925. (Fcap. 8vo, pp. vi + 170; 15 figures. 3s. 6d. net.)

<sup>5</sup> *Laboratory Outlines in Bacteriology and Immunology*. By John F. Norris, Ph.D., and I. S. Falk, Ph.D. Chicago Press: London: T. B. 8vo, pp. viii + 114. 10s. net.)

<sup>6</sup> *Aids to Case-Taking*. By Henry Lawrence McKisack, M.D., F.R.C.P. Lond. Second edition. London: Baillière, Tindall and Cox. 1926. (Fcap. 8vo, pp. vii + 168. 4s. 6d. net.)

<sup>7</sup> *Goldfish Culture for Amateurs*. By A. E. Hodge, F.Z.S., and Arthur Derham. With numerous photographs and drawings by A. E. Hodge. London: H. F. and G. Witherby. 1926. (Cr. 8vo, pp. 103; illustrated. 5s. net.)

## PREPARATIONS AND APPLIANCES.

## "Porcupine" Bottle Corks.

ATTEMPTS have been made to eliminate the accidental poisoning of patients by liniments and the like by constructing receptacles that appeal to one or other of the senses. Thus blue bottles for poisons appeal to the sense of vision, ribbing or corrugation in the glass to the sense of touch. The Waverley Comb Company (374-8, Old Street, E.C.2) proposes to make safety certain by appealing to the sense of pain. Hence the "porcupine" poison bottle stopper. This is an ordinary cork, attached to a disc of wood, which is covered with a tin cap. At four points in the circumference of this cap the tin is turned up into neat little pointed projections, which effectually prevent anyone from hastily withdrawing the cork without a warning of the possible consequences. Of the simplicity and efficiency of this little invention we have no doubt. We wish we could say the same of the intelligence of the patient who drinks from bottles in the dark.

## Cholecystography.

Burroughs Wellcome and Co. ask us to state that they can supply sodium salts of tetrabrom-phenolphthalein and tetraiodo-phenolphthalein for use in cholecystography. These salts may be obtained in gelatin capsules for oral administration, or in glass containers if intended for intravenous injection. Medical men should state the strength required when ordering.

## British Medical Journal.

SATURDAY, AUGUST 28TH, 1926.

### POOR LAW REFORM AND PUBLIC HEALTH ADMINISTRATION.

DURING the Annual Meeting of the Association in Nottingham there were two discussions relating to the Government's tentative proposals for Poor Law reform and to the opportunity which these proposals afford for far-reaching changes in health administration. One of these discussions was in the Representative Meeting in connexion with the approval given to the Association's Memorandum of Evidence for the Royal Commission on Local Government; the other was in the Section of Public Health. The former was fully reported in the SUPPLEMENT of July 31st (pp. 75 to 79), and the latter is reported on pages 376 to 385 of our present issue. The Memorandum of Evidence referred to was printed in the SUPPLEMENT of May 1st last (p. 172), and the subject has now become of such importance that we may with advantage refer to previous comments in our editorial articles of March 20th (p. 535), April 17th (p. 709), June 19th (p. 1048), and, with regard to its maternity service aspects, June 12th (p. 999). The Minister of Health is now engaged in considering the comments on his proposals which have been made by the British Medical Association, by associations of local government authorities, and by others; and he has himself carried the matter a little further by his recent announcement that his bill, when introduced, will be found to contain important proposals for the wider utilization of Poor Law hospitals. It is now possibly too late to exert any further influence on the form of the proposals in the forthcoming bill, but Mr. Chamberlain has stated that the first introduction of the bill will be for purposes of information and comment with a view to some possible modifications on its reintroduction next year. No doubt this undertaking will be carried out, as has been the similar undertaking by the Home Secretary with regard to the Factories Bill.

It is recognized that the most favourable opportunity for procuring modifications of Governmental proposals is by approaching the department of State concerned before its proposals take shape in a public bill. On the other hand, until the proposals are so formulated there is a real chance of any general memorandum being misunderstood and of tentative suggestions being misinterpreted. Such differences of opinion as were manifested during the two discussions at the Annual Meeting above referred to seem to have been largely due to this cause. It is important just now to emphasize the remarkable unanimity of opinion within the profession on this matter rather than to exaggerate any difference of view with regard to some particular detailed proposal which, however important, can probably be suitably adjusted. The attitude of the profession towards the proposals of the Government in general is one of warm welcome. This is natural enough, since the Association was a pioneer in the movement for Poor Law reform, and has been persistent and consistent in its advocacy for many years. There is a keen desire that the health services at present controlled

by the boards of guardians shall be separated from other services which have no essential connexion with them, shall be dissociated from any taint of pauperism in the minds of those they serve, and shall be united as closely as possible with other health services which are publicly provided or controlled. The anxiety of the profession is lest, in spite of the intentions of the Ministry of Health, some, perhaps many, local authorities under the new conditions should be allowed, on the plea of complete freedom of method, to effect these objects less fully or less perfectly than they might. There is real danger of this under the Government's proposals, and every endeavour should be made to strengthen in this direction the requirements of the proposed bill; or subsequently, if unfortunately too wide an option remains, to press the local health authorities to adopt such administrative methods as will effectively unify local health administration, and to establish machinery through which those who have experience of the various services and those through whom any advice and medical treatment must be given may exercise a due influence. The surest and simplest method of effecting this would be a statutory requirement for the establishment of a local health committee to which all health matters would stand referred for consideration, and on which there would be some assured representation of institutions and bodies of persons experienced in the work, together with a representative local medical committee to be consulted on appropriate occasions. The analogy of the education committee is obvious, and might well be followed. It is to be hoped that the bill will at least definitely permit the establishment of committees on these lines if it does not go so far as to require it.

The one proposal of the Ministry to which the Association is decidedly opposed is that by which "the county council shall in all cases definitely undertake for the whole administrative county a general oversight of the administration of all health services, whether existing or transferred," and shall be "the supervising and controlling authority for all health purposes." The arguments against any such provision for dual control and overlapping authority, at any rate in the case of the larger non-county boroughs and urban districts, appear to be overwhelming, and it is probable that some modification of this novel, sweeping, and reactionary proposal will be made before the bill is introduced. It is a matter of minor importance whether this be done positively by giving these large urban sanitary authorities full health powers, perhaps by delegation to them of such as they do not already possess, or negatively by making them exceptions from the general rule as applied to the more rural parts of counties. It is clear that there is, and may well be, some legitimate difference of opinion as to which of these methods is the better in the circumstances; but it is unlikely that the more pronounced divergence of opinion voiced by one or two of the county medical officers of health at Nottingham, that they ought to be placed in a position of authority superior to that of other medical officers, and that no one but themselves, or otherwise than through them, ought to be allowed to advise the county council on health matters, will receive any support whatever either from their colleagues in the public health service or from private practitioners throughout the country. It is to be hoped that the bill will be entirely free from any provisions under which such a dangerous and disadvantageous situation could be established.

Throughout these discussions it is of the first importance to bear in mind the two principles which the Association emphasizes in its Memorandum of Evidence. They are: "(1) the utilizing of the family doctor or private medical practitioner in domiciliary treatment of every kind and in the various clinics or treatment centres as far as possible; (2) the voluntary system of hospital support and management wherever possible." If these two principles are recognized and applied the duties and relative responsibilities of the various local government authorities will be much simplified. These are, the profession is convinced, essential conditions for success in any health services transferred to or established by local authorities. Without them the willing co-operation of the medical profession can scarcely be secured or expected. It is believed that they are recognized by the Ministry of Health and are being increasingly appreciated by local health authorities themselves. As we have previously said, "On the one hand, the oncoming of an autocratic municipal or county medical service is to be avoided, and, on the other, private practitioners of all kinds must be brought into responsible relationship with local health administration" if any real interest in preventive medicine is to be cultivated. Twenty years ago the late Dr. John McVail emphasized these conclusions after a very careful study of the Poor Law medical service and administration, and his wise and wide outlook may well influence the social reformer to-day:

#### CRIMINAL RESPONSIBILITY.

ANY opinion on criminal responsibility in relation to insanity expressed by a criminal lawyer of so much experience and eminence as Sir Edward Marshall-Hall, K.C., is worthy of careful consideration. No apology, therefore, need be made for referring to an article by him published a short time ago in a Sunday newspaper (*Sunday Express*, July 25th, 1926). The importance of the article is increased by the fact that its author was a member of the committee appointed by the then Lord Chancellor in 1922 to consider what changes, if any, were desirable in the existing law, practice, and procedure relating to criminal trials in which the plea of insanity, as a defence, was raised. The committee, which sat under the chairmanship of Lord Justice Atkin, reported in November, 1923. In support of the contention that the law as it at present stands and is interpreted sometimes leads to unsatisfactory results, Sir E. Marshall-Hall adduces three recent cases in which he was himself engaged. Lord Justice Atkin's committee recommended "that it should be recognized that a person charged criminally with an offence is irresponsible for his act when the act is committed under an impulse which the prisoner was by mental disease in substance deprived of any power to resist." The recommendation endorsed in substance the principal change in the existing rules suggested by the Council of the British Medical Association and its witnesses in the evidence submitted to the committee. The committee in its report expressed the opinion "that such cases as would be covered by the formula in this recommendation would, in fact, fall within the existing law, as suggested by Mr. Justice Stephen; and no doubt some judges have charged juries to that effect. On the other hand, there seem to be definite decisions of the Court of Criminal Appeal the other way. It seems to us that if this legal doubt should continue it would be advisable to make the law clear by an express statutory

provision. We have no doubt that if this matter were settled most of the criticisms from the medical point of view would disappear."

After the issue of the report a bill to establish this point by statutory provision was introduced into the House of Lords, but rejected. In the article before us we have criticism—not, be it noted, medical criticism, but criticism from an eminent criminal lawyer—alleging that, in fact, under the interpretation of the law as it now stands justice may not be done to the insane person. Assuming, then, as in view of this statement we fairly may without question of medical bias, that verdicts may be, and occasionally are, given under the direction of the judges which offend the sense of justice of the ordinary citizen, what remedy can be suggested? Sir Edward urges a modification of the law in accordance with the recommendation of the committee; but Parliament has already considered such a proposal and rejected it, and the committee itself held the view that such cases as are contemplated in its recommendation are or may be protected by the rules of law even as they stand to-day.

If this be so it would seem that more searching attention should be directed to the actual terms of the M'Naghten rules which embody the law on this matter, with a view to discover why they are differently interpreted by different judges, and whether it might not be possible by a clearer and broader interpretation to secure such a uniform application of them that injustice should be avoided. It is rather curious that Sir Edward does not direct his criticism to this aspect of the matter; indeed, he accepts without question the view that in all the cases which he relates the judge directed the jury quite properly that there was no evidence of insanity within the rules laid down in the M'Naghten case, although he holds that the accused should have been found irresponsible on the ground of mental disease. It is to be observed that in the discussion of his three cases, and when dealing in particular with one of them, he says: "The jury were properly directed that the only defence was insanity at the time the act was committed, the same test being applied: Did he know what he was doing and that what he was doing was wrong?" In regard to another case he states: "The jury were directed within the rule in M'Naghten's case, that if they found that the prisoner knew what he was doing and that he was doing wrong when he did it they must find him guilty."

Now each of these statements is a paraphrase of the words in the M'Naghten rule and not the exact words of the rule; yet it may be taken for certain that every word was carefully considered by the judges in framing these rules, and that they deserve, therefore, the utmost care and accuracy in quoting and applying them. The words of the rule are that "to establish a defence on the ground of insanity it must be clearly proved that at the time of committing the act the accused was labouring under such a defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing, or, if he did know it, that he did not know he was doing what was wrong."

There is one phrase in this rule which is habitually omitted as if it meant nothing, and it is, in fact, omitted by Sir Edward from the quotations in his article. It is fair to insist that it is not only the nature of the act which the accused did not know, but the nature and quality of the act. These words "and quality" deserve more consideration than they generally receive; they are a little unusual in everyday speech, and yet the word "quality" is not a technical

word any more than any of the others used in the rule. Indeed, it may well be supposed that the judges, in drawing up rules which were to be used in directing ordinary men of the jury, deliberately selected non-technical words and expected them to be used, as far as possible in such a difficult and abstruse question, in their non-technical ordinary sense. In particular may this be true of the word "know" also, which in its ordinary sense in such a context hardly means more than "be aware of," and it seems to be an unfortunate misconception for scientific people to seek to bound it and tie it down to some such technical connotation as pure "cognition." What, then, is meant by knowing, or being aware of, the quality of an act?

Elaborate interpretations of a far-fetched nature have been suggested by writers on this question, but in its simplest sense surely a "quality" is that which produces a feeling or sensation about the object possessing the quality. To know the quality of an act must therefore be to have such a sensation or feeling about the act as ordinary normal people would have—that is to say, to have normal feeling about the act.

Now sane behaviour, or sanity, depends on the coexistence in reason of these two elements—sane feeling and sane knowledge—as the springs and guardians of action. It is possible that the judges, in framing these rules, wrote more wisely than has been admitted by some of their critics, and that if we read them more attentively we may find in the true meaning of the terms they used a safe and natural escape from what would otherwise appear to be a hopeless impasse. Let us, therefore, consider the cases referred to by Sir Edward Marshall-Hall in the light of this suggestion.

In the first case an engineer, aged 28, shot his father-in-law, to whom he was greatly attached; after so doing he handed the gun to a person standing by, and said, "I've killed my best friend; send for the police." He had been greatly distressed by the attitude of his mother-in-law, who had practically insisted on a separation between him and his wife. In the second case a man in the middle of the night, without rhyme or reason, loaded a gun and shot his wife and one daughter, and when his other daughter, who was his favourite, questioned him he shot her also. Then he walked calmly to his office, lit a cigarette, and telephoned to the police, asking for an officer to be sent as he had shot his wife and child. In the third case a man, aged 24, who all his life had been regarded as weak in the head and abnormal, suddenly without any warning killed his step-brother, aged 14, with a chopper. The only motive suggested was that he was jealous because the boy had been given lessons at the art school. In the first and third cases the sentence was commuted, in the second it was carried out. In Sir Edward's opinion (and he must have been familiar with all the circumstances) it should have been possible for the jury to find in each case that the prisoner was "guilty but insane"—that is, irresponsible in the eye of the law—without doing violence to their oath or their duty.

If, as seems reasonable, we accept this as a correct view of the matter, might it not properly have been held in each case that the accused was labouring under such a defect of reason, from disease of the mind, as not to have the normal feeling about the act he was committing, not to perceive its horror or enormity, even though he had a normal knowledge of what he was doing, and so, in the terms of the rule, he did not know the nature and quality of the act? That is

surely what was implied by the prosecuting counsel in one of these cases when he said, "the real defence was the crime itself."

Hitherto the stress has usually been laid entirely on whether there was knowledge of the nature of the act, or, as the common paraphrase has it, on whether the accused knew what he was doing; and this usage is illustrated in Sir Edward's account, as has been already pointed out. The effect is to divert attention from the actual expression used in the rule, and, indeed, to alter its meaning. For in the rule it is clearly contemplated that if the accused does not also know the quality of the act he may be held to be irresponsible in law. It is difficult to see how this can mean anything but a sense or appreciation of values, which is something different from and in addition to mere recognition of facts. Is it not possible that this view of the matter may supply the solution of the difficulty that Sir Edward points out, and do this without undue straining of the existing law or the need for remodelling it, and may show the way to prevent in similar cases in future such a miscarriage of justice as he now deplores? If so, the question how this interpretation may best be brought before the courts and pressed upon their consideration is one with which Sir Edward would be most eminently qualified to deal.

One further remark may be made. There is a natural reluctance on the part of the Legislature to modify the law in any way which might make it difficult to maintain the proper degree of responsibility in connexion with minor offences. It does not appear that any such danger would arise from the wider interpretation of the M'Naghten rule here suggested.

#### THE SCIENCE OF SEA BATHING.

BATHING in the sea has long been regarded partly as a cult and partly as a pleasant pastime, but it has been left for a more modern age to emphasize more particularly its importance as a therapeutic measure and to assign to it a scientific basis. Since 1791 the Royal Sea-Bathing Hospital at Margate has stood as a witness of the value of sea water in treating surgical tuberculosis, and sea-bathing infirmaries were established at Southport in 1806, at Scarborough in 1812, and at Felixstowe in 1868. We have, therefore, not lagged behind in this country in appreciating the possibilities of sea bathing in medical treatment as well as in the holiday programme, and the tonic effects of sea breezes are a matter of general knowledge, but comparatively little attention has been paid to the way in which the beneficial results are produced. In the *Revue Scientifique* for July 10th Dr. G. Baudouin examines sea bathing, viewed as a curative procedure, with particular reference to the physical and physiological questions concerned. Importance is attached to the chemical and physical properties of sea water, especially the proportion of salts, which vary in different places; the temperature factor has never been underestimated, even by the unscientific. The question is complicated by the fact that the influence of the marine air and of sunshine cannot be ignored when estimating the nature of the action of sea bathing. Heliotherapy of an empiric kind in combination with sea bathing was a recognized practice in early times on the sea coasts of Syria, Greece, and Italy, though it is only in later days that the importance in this connexion of the relative scarcity of solid particles in the sea air has been appreciated. Yet another factor in therapeutics, to which attention has been drawn by Professor Pech, is the degree of ionization of the air, which depends largely upon local geological and meteorological conditions. The action of

the sea and sea air in increasing human vitality in impaired nutrition is believed to be due to a stimulation of metabolism, which may, however, be injurious to patients with heightened irritability of the nervous system, or of such organs as the heart, stomach, and liver. When these conditions are present, even in minor degrees, such stimulation causes a holiday by the seaside to be productive of bad rather than of good results. Patients with impaired powers of assimilating phosphorus, or with such increased activity of the oxidative processes as is found in pulmonary tuberculosis or febrile disorders, must therefore avoid the seaside, since in them katabolism is already excessive. In his further inference that such clinical points might be carefully considered before recommending a seaside holiday, Dr. Baudouin would seem to approve the underlying principle of a certain current advertisement illustrating the type of man who needs a holiday on the coast, as contrasted with the older style of poster, which rather implied that any seaside resort would suit anybody. He mentions a number of French seaside towns, and indicates whether they may be considered stimulating or sedative. He clearly disapproves the common practice of recommending the proverbial holiday by the sea for all and sundry, without a rather elaborate consideration of the circumstances. Dr. Baudouin also gives a somewhat alarming description of the physical effects of a sudden unconsidered dash into the sea, mentioning peripheral and central vascular changes, together with cardiac and respiratory disturbances; the gravity of his warning is only slightly qualified by the assurance that such phenomena are usually transient. He speaks more approvingly of the familiar slow and hesitating entry, with repeated halts and occasional retreats, and it would appear that science must now be called upon to regulate yet another of the activities of life. The careful man who contemplates taking a seaside holiday will presumably first submit to an elaborate examination of his physical condition by biochemists and physicians, after which the geographical, geological, hydrological, and meteorological characteristics of possible resorts will be studied in detail before a decision is reached. That there is something to be gained by making a more scientific investigation of the value of sea bathing is undeniable, but it is curious to find a Frenchman suggesting that we ought to take our pleasures more seriously, if not more sadly. We expect, however, that the public as a whole, both in France and England, will continue to be guided by the recommendation of friends and the posters of the railway companies, and will trust individual metabolic capacities to rise to the occasion.

#### DISPENSING OPTICIANS.

AN Association of Dispensing Opticians has recently been formed as the result of the very general opinion of dispensing opticians throughout the country that the time has arrived for the formation of an organization devoted to the interests of the dispensing section of the optical trade. Membership of the association is confined strictly to those engaged solely in optical dispensing work and their employees, and in no circumstances is an optician who professes or practises sight-testing admitted to membership in any grade. There are four grades of membership, for which certificates are issued: employers, managers, assistants, and craftsmen. The main object is to secure a high standard in the work of dispensing; every effort will be made to ensure that only dispensing opticians of proved ability and experience shall be admitted to the Grade A membership. Medical practitioners and the public may be assured that the holder of this certificate is a fully trained and experienced dispensing optician, who possesses the necessary plant, facilities, and skilled staff satisfactorily

to dispense optical prescriptions and to manufacture spectacles. Lectures and classes are held for the instruction of members, and examinations take place periodically in order that members may pass from one grade to another. The syllabus of instruction is printed in the pamphlet setting out the scheme of the association. It differs materially from those of other optical courses of instruction, and should prove of great value to the trade, dealing as it does with the work and problems peculiar to those engaged in optical dispensing. The association is governed by an executive committee of seven, elected by the members, each of whom, irrespective of grade, is entitled to one vote. The association is precluded from engaging in any wage questions or trade disputes. A candidate for membership is required to have at least three years' experience before taking the preliminary examination, and a further twelve months' experience before the final examination is taken. We are informed that it is proposed to circularize all the ophthalmic surgeons of the country setting out the principles of the new association. We feel sure that this move will receive a warm and generous appreciation from members of the medical profession, and ultimately from the public. Ophthalmic surgeons cannot do their work without the fullest co-operation of the members of the optical craft, and there has never been wanting a whole-hearted appreciation of the value of the work done by this great craft in the beneficent cause of medicine. Nothing will better serve to enlighten public opinion as to the separate although related fields of work of the doctor and the optical craftsman than the work of this association; for the public will learn (some for the first time) that there are opticians so proud of their craft, and so completely engaged in the improvement of manufacture and dispensing, that they decline to trench on the sphere of the doctor or seek a fictitious importance by pretensions that mystify the public. It is to be hoped that membership of the Association of Dispensing Opticians, which has its offices at 439-441, Oxford Street, London, W.1, will be wide, and that the activities of the association will be supported by individual members of our profession.

#### NEW ZEALAND HOSPITALS.

It is always of interest to see how others do the thing we have to do, especially when the doing of the thing involves difficult problems. Information of the working of hospitals in the Dominions is therefore of peculiar interest. Dr. Clennell Fenwick has done good service in this connexion by writing an account of *The Christchurch Hospital*.<sup>1</sup> It was started some sixty years ago, and is now the base hospital of a large number of linked hospitals and sanatoriums throughout the province. It began as a small local hospital to meet the needs of the pioneer settlers; the site was given by the provincial Government, and it was proposed that lands should be sold to defray the cost of the building, but this was negatived; eventually the hospital was built, but by whom and at what cost cannot be traced, though there is evidence that an appeal for funds was made to the settlers. It would appear, therefore, to have begun somewhat in the fashion of a "voluntary" hospital, albeit with some State help. The management was in the hands of a board of governors, who attained their position by reason of subscriptions, or, as the *Lyttelton Times* wrote at the time, "on a footing similar to that of other institutions of the kind in England." But funds were not contributed in sufficient amount, and the fees received from patients did not

<sup>1</sup> *The Christchurch Hospital: Historical and Descriptive Sketch*. By P. Clennell Fenwick, C.M.G., M.D., J.P., etc. Christchurch, New Zealand: Andrews, Baty and Co., Ltd. 1926. (Demy 8to, pp. 58; illustrated.)

meet running costs. From the outset patients paid according to their means, and the medical staff was paid. Two years after the start finances were so strained that the governors, in the words of the local press, "trembling and terror-stricken, dropped their burden at the feet of the Government." The Government refused to make the hospital a State charge, but passed a bill putting both hospital and charitable relief upon a system of local rating. There was strenuous opposition to this "as the first step towards the inauguration of the British work-house system." The rating system was carried into effect, but troubles did not end. Ten years later the local press has: "The charitable aid question is at present between the devil and the deep blue sea. On the one hand the Government . . . has cast them off; and on the other, the local bodies, while paying for the cost of maintenance of the various institutions (this they cannot avoid) are not in a fit frame of mind to consider any scheme of benevolence. . . . The blighting shade of centralism has crept over our local institutions." A new board was formed, and the Government met half the cost of the hospital by subsidy, the remainder being obtained from rating. Hospitals and charitable aid were put under separate boards for some dozen years, but in 1909 a new Act brought charitable aid under the control of the hospital board. The action of a magistrate in remanding a prisoner suffering from delirium tremens to the hospital charge brought about something like an association of hospital boards through the islands for common action. This story suggests that the hospitals were becoming more and more State supported and controlled institutions, but there is evidence that the managements retained a considerable degree of independence, and that hospitals made a strong appeal to local patriotism which was reflected in many and generous private benefactions. One of the largest wards was built and endowed to the cost of £20,000, in 1895, by a Polish Jew, who averred that there was no flag fit to live under but the British, and in proof he left all his possessions to the land of his adoption. Now the hospital is complete with every type of special and general department, with a great block for chronic cases, built at the cost of a lady benefactor. Recently a radium and deep therapy department has been added, the cost of which has been defrayed by an anonymous donor. We have before us the first report of the department, written by the officer in charge, Dr. Clennell Fenwick, who is also consulting surgeon to the hospital and a member of the board of governors. The hospital already possesses over £8,000 worth of radium, while the Victor deep x-ray machine was installed at a cost of £4,000. A careful "follow-up" system is enabling the after-history of the majority of patients to be ascertained. Already over 500 cases have been treated since the department was opened in November, 1924. The hospital has a share also in prevention, for it controls a large department for venereal diseases, and organizes and maintains "The Social Hygiene Society," which carries on health propaganda through the province. The hospital board is also responsible for "charitable aid," a heavy business. It was hoped that the Old Age Pensions Act of 1898 would decrease the cost of charitable aid. It did not. Children deserted their parents so soon as they obtained a pension. Ultimately the pensions of aged persons in institutions were paid to the board in reduction of cost of maintenance. There is caustic comment on the inhumanity of some classes and the modern scorn of the fifth commandment. In a section dealing with future development a strong plea is made for a widening of the hospital idea; it should be "The Best Community Hospital." It should cater for the private or paying patient, "the private patient who might be described as one who financially is prepared and required to pay for private services . . . and the privilege

of choosing any reputable qualified physician or surgeon who may be practising in the hospital area, and who is responsible for his own professional fees." Semi-private wards, it is urged, would reduce the costs of the public wards, and help "the poorest section of the community, the middle class." Dr. Clennell Fenwick is to be congratulated on the result of his labours, for he has shown how, in one place, the apparent antagonism of State and private enterprise can be reconciled for the common good.

#### AMAZONIA AND ITS DISEASES.

IN 1924 Dr. and Mrs. Hamilton Rice, who have for long actively encouraged scientific exploration in South America, sent out a seventh expedition, organized in conjunction with the Department of Tropical Medicine of Harvard University, which spent a considerable time on a river steamer on the Amazon and two of its chief tributaries. The purpose of the expedition was geographical exploration and medical investigation. A report<sup>1</sup> has now been issued in a well illustrated quarto volume. It is a record of excellent work, carried out with the care and accuracy of detail which we expect from a body of men led by Dr. R. P. Strong, professor of tropical medicine at Harvard. The other members were Dr. George C. Shattuck, assistant professor of tropical medicine in the same school, Dr. J. C. Bequaert, assistant professor of entomology, and Mr. Ralph E. Wheeler, a graduate of Harvard. The report is divided into three parts, each containing several sections: the first part is of the greatest interest to the tropical practitioner, the second to the specialist in entomology; the third part, written chiefly by Dr. Shattuck, relates observations made on some of the tributary rivers. The members of the expedition were clearly not enamoured of the reputed fascinations of the forest of the Amazon. They state that Rangel appropriately named it the *inferno verde*, "where one soon dies of hunger, and, during the dry season, suffers from thirst, when almost all the streams which traverse it are reduced to some few puddles of stagnant or brackish water. It is too thickly and too regularly grown to be grand or picturesque, and too silent to be cheerful. It breeds too much vermin to be agreeable, and produces at length upon the traveller vague sensations of sadness, oppression, and uneasiness." The climate must be trying indeed, for at Manáos, where, and at Para, the expedition spent much of its time, the average temperature is 28.2° C., and the humidity varies between the extremes of 54 and 99 degrees. In the lower Amazon the seasonal variation in temperature is small. Many excellent reproductions of photographs show the general character of the scenery and vegetation, and there are others of the inhabitants and their dwellings. Next, the various prevalent diseases are dealt with. Of the spirochaetoses, syphilis is very rife. Amongst a population of 50,000 in Manáos and its environments there were recorded 13,858 male and 8,475 female cases in the years 1922 and 1923. Yaws is not very frequent. It is stated that some confusion may arise because the term "boubá" is applied, not only to this disease, but to various other forms of ulceration, such as those due to leishmania and blastomyces. Yellow fever, of which many disastrous epidemics occurred in Amazonia during the last century, took a toll from 1903 to 1912 of about 100 cases a year in Manáos alone: it was dealt with seriously from 1911 onwards with marked success. Weil's disease and rat-bite fever (included here among spirochaetral diseases, though the causative organism is probably a spirillum) are met with, but not commonly, and relapsing

<sup>1</sup> Cambridge, Mass.: Harvard University Press; London: H. Milford, Oxford University Press. 1926. (Imp. 8vo, pp. xv + 313; illustrated.)

fever is rare. In the pages on the chronic inflammatory and ulcerative dermatoses an excellent account is presented of *ulcus tropicum*, its history, pathology, possible mode of transmission, and treatment; the description of granulomatous dermal spirochaetosis and "mossy-foot" is illustrated by good photographs of the lesions and coloured plates of the histological appearances. Leprosy is said to be spreading in Amazonia; little appears to be done by way of prevention. The usual mode of treatment is by chaulmoogra oil or its derivatives, but many patients fail to improve even after prolonged courses. Promising results have been obtained by the intravenous injection of 1 per cent. solution of mercurochrome in doses of 2.5 mg. per kilo of body weight. In the section dealing with trypanosomiasis, mal de Caderas, Chagas's disease, and infection of tamandua (anteater) with *Trypanosoma legeri* are described, and there is a coloured plate demonstrating the main characteristics of the last named. Good work has been done on some of the parasitic infections of animals, such as balantidiasis, myiasis, nematode infestations, haemogregarines, and so on. The second part, which is concerned with medical and economic entomology, contains descriptions of the various genera and species encountered, and will be of interest to the entomological enthusiast. A point worthy of special note is the fact that there seems to be a great dissimilarity in the fauna of the regions of Southern Brazil and the Amazon basin. In the third part Dr. Shattuck relates his observations on the Branco, the Uraricuera, and the Parima rivers; he describes these districts and their crops and animals, makes remarks upon the diseases prevailing amongst the natives, and gives a list of the birds, beasts, and reptiles met with.

#### ILLUMINATION AND VISUAL CAPACITIES.

In 1924 the Council of the British Medical Association referred a resolution, unanimously adopted by the Ophthalmological Section of the Annual Meeting, to certain Government departments and to the Medical Research Council. In the terms of the resolution the Association was recommended "to press strongly upon the Government the great need for research upon many problems of vision in relation to the requirements of the combatant services." The stimulus afforded by that resolution was fruitful, for the Medical Research Council, after consultation with the Admiralty, the War Office, and the Air Ministry, appointed a committee to initiate and supervise research work in the physiology of vision, and in so doing to promote as far as possible the attention paid to the subject generally at the universities and other centres. At present very little work, so far as we are aware, is being done on the subject at the universities, and the need is urgent, both for the advancement of primary knowledge and for practical requirements, particularly in medical work. The firstfruits of the establishment of the committee (of which Sir John H. Parsons is chairman) appears in the publication<sup>1</sup> of a critical survey of the work already done in this and other countries in some parts of the applied physiology of vision. The Council made arrangements with Mr. R. J. Lythgoe to prepare the analysis, and he has done his work admirably. In a pamphlet of eighty pages he has given a summary of all the observations published in recent years, and has included references to critical earlier work. Among the matters dealt with are definitions; the influence of different intensities of illumination and the character of illumina-

tion on visual acuity; the discrimination of shapes and differences of brightness, and the effects of adaptation; the influence of glare on visual judgement; the speed of retinal impressions in relation to telegraphic signalling; colour vision; and visual fatigue. An extensive bibliography is also provided. No more serviceable work could be put into the hands of the research student who desires to follow up references to work in hand; and the school doctor and ophthalmic surgeon will find points of interest in these summaries which will stimulate them to reading and experimentation.

#### GUIDE TO OFFICIAL STATISTICS.

THERE is a Permanent Consultative Committee on Official Statistics, on which the majority of Government departments are represented. This body has now issued fourth *Guide to Current Official Statistics*, an ingenious compilation by means of which the inquirer is directed to the particular current official publications which contain statistics bearing on his subject, and is informed of nature of the statistics he will find in the volumes which he is referred. The secretary to the committee Mr. F. A. A. Menzler, gives a very clear statement of way in which the guide should be used. The system of cross-reference has been so skilfully applied that every reference in a subject index of 187 papers can be found by starting from only twenty-six headings. Consequently, if there is any difficulty in tracing a subject is only necessary to select that heading of the twenty which seems most appropriate to the matter of the inquiry and the subject is sure to be found in the cross-reference under that heading. If it is desired to know what material are exhibited statistically in a particular publication key which has been added to the guide will refer searcher to pages in the subject index. The guide costs 1s., and is obtainable at the sale offices of His Majesty's Stationery Office, Adastral House, Kingsway, W.C.2, or at the branch offices in Manchester, Edinburgh, Cardiff and Belfast, or through any bookseller.

#### THE EDUCATIONAL NUMBER, 1926.

OUR next issue, dated September 4th, 1926, will be the annual Educational Number of the BRITISH MEDICAL JOURNAL. The customary sections, giving a summary of the requirements of the universities and other licensing bodies in Great Britain and Ireland, have been brought up to date, and the information showing the opportunities offered by the various medical schools and other teaching institutions has been corrected by the authorities concerned. These sections, whose purpose is to give concise guidance to intending students of medicine and newly qualified practitioners, will be supplemented, as usual by articles on such matters as post-graduation study, public health services, the medical education of women, tropical medicine, and psychological medicine. The introductory article on the profession of medicine has been amplified and revised throughout. In the section on public services will be found full particulars of the new and improved terms and conditions of service in the R.N.M.S., the R.A.M.C., and the R.A.F.M.S., which the Representative Body of the British Medical Association has decided are satisfactory and such as can be recommended to the notice of the younger members of the profession. The opening article for this year's Educational Number has been written at our request by Arthur Keith, who discusses with characteristic clarity and wisdom the place of anatomy in medicine.

Lythgoe, M.A., B.Ch. London: H.M. Stationery Office, or through any bookseller. 1926. (Pp. 89. Price 2s. 6d. net.)

## SANATORIUM TREATMENT.

WITHIN recent years several investigations have been carried out with the view of determining the value of sanatorium treatment for tuberculosis. The method adopted has been to trace the after-histories of cases of tuberculosis treated in these institutions and to compare the mortality according to the condition on admission or discharge with that experienced by the general population at corresponding ages as shown by a life table. An inquiry of this nature was carried out by Elderton and Perry in the Galton Laboratory in 1910 on data derived from the Adirondack Sanatorium in America. More recently somewhat similar inquiries have been made from data from Midhurst Sanatorium by Bardswell and Thompson, from Frimley Sanatorium by Hartley, Wingfield, and Thompson, and from Bradford Sanatorium by Vallow. The results of these investigations have been published in reports of the Medical Research Council. Though a considerable amount of valuable information was obtained from these investigations, they all suffered from the defect that they measured progress only by survival, and that no comparison could be established between the after-histories of the tuberculous cases treated in sanatoriums with the after-histories of other contemporary series of cases from the same districts treated by other methods. Such a comparison, not only as regards mortality experienced but as regards progress towards recovery measured in other ways, has now been made in the Galton Laboratory by Dr. Percy Stocks, assisted by M. Noel Karn, and the results are contained in a memoir on the influence of sanatorium and dispensary treatment and housing conditions on pulmonary tuberculosis which has been recently published in the *Annals of Eugenics*.<sup>1</sup> The results obtained from this investigation are of interest and importance in view of the fact that they deal with the treatment of pulmonary tuberculosis in sanatoriums. Though there has been doubt in the minds of some people as to the permanent improvement in the disease to be obtained from sanatorium treatment, the results of previous investigations seemed to suggest that the educational value of such treatment was considerable, in that the patients were taught the principles of a more correct mode of life which had a good influence on their subsequent progress, and, if effectively carried out, might be expected to lessen the spread of infection. The results of this investigation suggest that this view has been too optimistic.

The memoir is based on an exhaustive study of the first 2,794 consecutive cases of undoubted pulmonary tuberculosis brought under the survey of the Belfast Tuberculosis Dispensaries from 1914 onwards. All the cases were examined in the first instance at the dispensaries and a certain proportion of them were recommended for treatment in sanatoriums. Those who remained at least fourteen days in these institutions, in addition to being under observation and receiving dispensary treatment before and afterwards, are defined as "sanatorium treated"; the patients who only received dispensary or domiciliary treatment are described as "otherwise treated." In assessing the stage attained by the disease when the patient first came under observation, the cases were classified separately on an anatomical basis into the three grades, incipient, moderately advanced, and far advanced, and according to the amount of systemic disturbance into slight, intermediate, and severe. Progress was estimated at the end of every three-monthly period from the date of the first visit until the patient was dead or lost sight of, or until six years had elapsed. The patients were at these intervals assigned to one of the following categories: dead, progressive or stationary, improved, arrested, and apparently cured. For the purpose of establishing a legitimate comparison between the progress of the "sanatorium treated" and the "otherwise treated," it was essential to determine and to make allowance for whatever kind of selection had been exercised in recommending cases of phthisis for sanatorium treatment. It was believed

that any factors likely to have an important influence on subsequent progress would come under a selection based on the grounds of sex and age; the stage which the disease had reached in the lungs; the severity of constitutional symptoms; the nutrition of the patient; the amount of deterioration since coming under observation; his financial resources, the quality of his dwelling, the amount of overcrowding in his home, or his family ties.

The progress of the "sanatorium treated" and the "otherwise treated" was first compared by a method described as an "exposed to risk" basis. For this purpose the patients were divided (1) into sexes; (2) into two age groups—under 20 and over 20; (3) into groups of those in the three initial stages of disease; (4) into different subgroups of treatment. Then in each subgroup the number of patients surmounting each step of progress at the end of 1, 2, 3, 4, 5, and 6 years, and the total number at these periods whose fate or condition was known at the time was determined, and the progress of various subgroups at the yearly intervals was compared by means of ratios to those at risk or to expected mortality. In the second part of the memoir the method of correlation by alternative categories was used to determine the relation between treatment—both as regards form and amount—on the one hand, and progress and some factors that influence it on the other. By partial correlation it was possible to correct for the principal factors considered likely to influence progress. The authors state that as impartial workers they entered on the research in the belief that proof of the ultimate benefits of sanatorium treatment would emerge from it. To what extent this expectation was realized may be ascertained from their principal conclusions, which may be given more or less in the terms used in the memoir.

1. The average ultimate progress was undoubtedly worse in the "sanatorium treated" than in the case of the "otherwise treated" for patients first seen in the incipient stage, but was not significantly different for patients first seen in the two advanced stages. This relation held in both sexes and for young people and adults alike, whether progress was estimated on a survival basis by the ratio of actual to expected mortality, by the proportion improving to any degree, or by the proportion in whom the disease became arrested or apparently cured. This conclusion was reached after as full consideration as possible of the effect of selection of cases in biasing the prospects of the sanatorium cases. Adequate correction was made for selection on account of age, sex, stage of the disease, and severity of symptoms; selection on account of poverty, overcrowding, and bad home conditions was shown to be negligible in its effect on progress.

2. These results obtained by the preliminary method of analysis were confirmed by those of the correlation method by alternative categories. Having made every possible correction for factors likely to influence progress, sanatorium treatment as contrasted with the other forms of treatment was associated to a significant degree with inferior progress. The correlation method also proved the absence of any relation between length of stay at the sanatorium and ultimate progress, but on the other hand indicated an appreciable relation between regularity of dispensary treatment and progress.

3. The initial stage of nutrition had no appreciable relation to ultimate progress in adult males and only a slight relation in adult females.

4. There was no consistent evidence that bad housing conditions, as judged by rent, class of house, state of cleanliness of rooms, or overcrowding, had any influence on the patient's ultimate progress or rate of recovery.

These are the principal results of the investigation, and the only explanation of this unexpected state of affairs that suggests itself to the authors is that the depressing psychological effects of a long period of enforced idleness in the company of patients similarly affected may in the bulk of cases counteract or even outweigh such benefit as may arise from other factors, and that the continued effort to "carry on" at home may help in itself towards a mastery of the disease.

The authors complete their memoir by stating that if their conclusions are sound it would be well to consider (1) whether the great inconvenience to themselves and their families inflicted upon many cases of phthisis by sending them as a routine procedure for long periods to sanatoriums is justified by the results, and (2) whether the sanatorium treatment should not be reserved for those in whom an unusual form of onset (for example, haemoptysis) has made a very early diagnosis possible, those who are so ill as to require hospital treatment, or those whose circumstances demand their removal from home.

As the results of this very exhaustive and important

<sup>1</sup>The Influence of Sanatorium and Dispensary Treatment and Housing Conditions on Pulmonary Tuberculosis. By P. Stocks, M.D., D.P.H., assisted by M. Noel Karn. *Annals of Eugenics*, vol. 1, Parts III and IV, April, 1926, pp. 407-454. Cambridge: The University Press. (Med. 4to, illustrated. Annual subscription, 50s. net; double parts, 35s. net.)

investigation seem to be at variance with more or less generally accepted beliefs regarding the advantages that accrue to tuberculous patients from treatment in sanatoriums, it would appear to be desirable to attempt to obtain without delay confirmatory evidence for some districts in this country where the prevailing type of pulmonary tuberculosis may be different from that in Belfast.

## THE METROPOLITAN ASYLUMS BOARD.

### REPORT FOR 1925-26.

THE annual report of the Metropolitan Asylums Board for 1925-26, which is a large volume of 366 pages, takes the form of a general review of administration and a special survey of each of the four main departments of the Board's medical work—namely, infectious diseases, mental diseases, tuberculosis, and sickness in children—supplemented by contributions from medical superintendents and others on interesting cases or particular phases of the work. The Board serves an area of 121 square miles, with an estimated population of 4,600,000. It has fifteen hospitals for infectious diseases, six mental hospitals or colonics for the feeble-minded, ten institutions for tuberculosis, and five for sick or convalescent children. It has also an ambulance service which during the year transported 80,000 patients. The statistics given relate generally to the year 1925, but some account of the work of the Board is given up to May, 1926, which is the end of the Board's administrative year. The provisional proposals of the Ministry of Health to transfer to the London County Council the oversight of all health services, including those for which the Board is responsible, are regarded with disfavour by the Board, which is convinced that the Council would find it impracticable to undertake this substantial addition to its present duties and at the same time to maintain a close contact between the elected representatives of the public and the work so transferred. The Board urges the desirability of its continued existence as a separate body.

### Infectious Diseases.

For fever cases the Board has 8,620 beds; the largest number of cases under treatment at any one time in 1925 was 5,495 (in November). The total number of cases of infectious disease, exclusive of chicken-pox, tuberculosis, whooping-cough, and zymotic enteritis, notified during 1925 was 44,504, or 10,861 more than the previous year, but 13,481 fewer than in the epidemic year (1921). The case mortality rates for all diseases, with the exception of whooping-cough, were low. The diphtheria rate (4.57 per cent.) was the lowest yet recorded, that for scarlet fever (1.07 per cent.) was the lowest except in 1921, and the rate for enteric fever (8.44 per cent.) has only twice been lower; whooping-cough (13.37 per cent.) showed almost the highest case mortality recorded. During the year eleven patients suffering from small-pox were admitted to hospital; ten recovered and one died. The only serious outbreak was at Bethnal Green, where a man was stated to have acquired the infection through handling foreign rags; this man infected his wife and two children, and within three months four additional cases were admitted from the same locality. Of the eleven patients eight had been vaccinated in infancy only (that is, from twenty-seven to sixty-six years before); in the other three there was no evidence of vaccination.

The incidence of diphtheria was unusually high. The admissions for diphtheria and membranous croup numbered 10,251, out of 12,595 notifications. The Board has arranged for certain researches to be made into the microbic flora of the throat and nose in diphtheria carriers, with a view to ascertaining, among other things, at what points the bacilli appear to be specially liable to persist and the anatomical conditions associated with such persistence. The figures for scarlet fever are curiously close to those for diphtheria—10,568 admissions out of 12,298 cases notified; and the same approximation shows itself in the average period of residence of recovered patients at the "acute" hospital—fifty-nine days for diphtheria patients, fifty-seven for scarlet fever. The largest number of attacks of scarlet fever occurred in the second quinquennium of life, whereas

in diphtheria it is in the first quinquennium that the attacks were most frequent. Dr. Foord Caiger, chief medical officer of the infectious hospitals service, raises the question whether the policy hitherto pursued by the Board of according priority of claim for hospital isolation to scarlet fever as against measles is justified in view of the very low mortality of scarlet fever. Of the 10,508 scarlet fever patients admitted to the Board's hospitals only 111 died, whereas of the 1,902 cases of measles the deaths numbered 121. He thinks that, having regard to the failure of hospital isolation to limit the spread of scarlet fever, to the much higher mortality of measles, and to the beneficial effect of hospital treatment on the course of the disease when occurring in children from poor homes, the policy should be reversed and the preference given to measles. Of the infectious cases received at hospital during the year the diagnosis of the certifying practitioner was not confirmed by the medical officer of the hospital in 15.2 per cent. Among the common diseases mistakes were most frequent in respect of enteric fever; 31.2 per cent. of the cases so certified were found to be suffering from some other disease. In cerebro-spinal fever, for which there were only 17 admissions, and encephalitis lethargica (32 admissions), the proportion of mistaken diagnoses rose to 56.4 and 56.8 per cent. respectively, though it is admitted that with regard to the latter disease, by reason of the frequently anomalous character of the symptoms, the original diagnosis might not have been incorrect in some instances.

The Board has adopted certain suggestions put forward by the Ministry of Health to concentrate puerperal fever patients in two or three hospitals, so that such patients may receive more skilled medical and nursing attention and greater opportunities for research may be afforded. Such cases, therefore, have been concentrated in the Eastern, North-Western, and South-Western Hospitals, and a visiting obstetric consultant has been appointed. The number of cases of puerperal fever admitted to hospital in 1925 was 87, only slightly in excess of the number admitted during the previous year, and the case mortality was 23 per cent. It is hoped that with another year's work in the clinical unit much information with regard to the infecting organisms and other matters will be elicited and the prevention and treatment of the disease advanced.

### Mental Cases.

The cases remaining in the Board's mental institutions on December 31st numbered 9,352. These included cases certified under the Lunacy Acts, but chronic and harmless, and under the Mental Deficiency Act, as well as sane epileptics, uncertified feeble-minded, and poor aged persons who by reason of mental infirmity required institutional treatment. The average annual number of admissions during the past three years has been 1,424. Pathological laboratories are now provided at three of the mental hospitals, and another is to be established at a fourth. Many cases of abnormal mentality following upon encephalitis lethargica have been received into institutions controlled by the Board, and arrangements have been made for a special group of them to be dealt with separately, and 100 beds have accordingly been set apart at the Northern Convalescent Hospital. The admission of these patients did not begin until November last, and it is premature to speak of results, but the comment is made by Dr. Kinnier Wilson, consulting neurologist to the Board, that much less difficulty has been encountered than was expected in regard to cases of inversion of sleep rhythm, and that the atmosphere of the unit with its system and discipline has proved favourable in cases of behaviouristic impairment. Stress is laid upon the particularly heterogeneous character of the clinical material.

### Pulmonary Tuberculosis.

The admissions to institutions for pulmonary tuberculosis numbered 3,953, and the discharges 3,601. The average duration of stay at the three sanatoriums (for men, for women, and for children) was 133 days. At Colindale Hospital, which is for advanced male cases, the average stay for discharged patients was 142 days, as compared with 117 days in 1924. In the two sanatoriums for adult cases—King George V Sanatorium at Godalming,

and Pinewood Sanatorium at Wokingham—out of 1,095 cases discharged (in 863 of which tubercle bacilli had been demonstrated in the sputum at one time or other) the disease was declared to be quiescent, with no signs or symptoms other than those compatible with a completely healed lesion, in 33 per cent.; 39 per cent. were much improved, implying that the general health was good, the working capacity more or less restored, and the signs and symptoms materially diminished. The percentage of recoveries shows improvement on the average of the three preceding years, and in the opinion of Dr. James Watt, chief medical officer of the medical tuberculosis service, the figures indicate again how the prospect of recovery depends more on the degree of constitutional disturbance than on the extent of the damage done to the lungs. Dr. W. C. Fowler describes some difficulties in the search for early cases of pulmonary tuberculosis, one of which is lack of moral courage on the part of the patients to face a situation they suspect to be serious; other cases may be misleading when the neurasthenic symptoms are the first to prevail, or when the early manifestations are those of anaemia or amenorrhoea. The only way of avoiding some at least of the delays in diagnosis is to suspect the lungs as guilty in all cases of ill health until they have been proved innocent by the most careful and repeated clinical examinations. Dr. J. G. Cummins describes a typical case of pulmonary tuberculosis treated by artificial pneumothorax. The treatment has extended over almost two years, and the disease appears to be completely quiescent.

#### *Surgical Tuberculosis and Children's Diseases.*

To the section dealing with non-pulmonary tuberculosis Dr. W. T. Gordon Pugh contributes the paper on the relative value of open air, sunlight, and artificial light in treatment, which he read before the Harveian Society in March, and which was reported in our columns (April 10th, p. 657). In that article he described the work done at St. Mary's Hospital for Children, at Carshalton. Dr. N. Gray Hill, of the same institution, contributes an article on ultra-violet radiation from artificial sources, in which his conclusions are that patients with superficial tuberculous ulcers, rickets, and debility do well, but that such cases are easily treated without the use of light; that the local application of the rays is of value in the treatment of lupus, but the general light bath has little effect; that the course of tuberculosis of the spine, hip, or knee, with or without sinuses, is not apparently influenced in any way by the action of light; that the treatment gives no protection against the spread of infection; that pigmentation has little or no clinical significance, and that light treatment has no definite influence on the physical or mental development of the normal or subnormal child.

In January last the Board approved the provision of accommodation at St. Mary's Hospital for Children for 36 girls and 24 boys suffering from rheumatic fever, acute endocarditis, and chorea, and, following a suggestion by Dr. Gordon Pugh, the Board decided later that these beds should be utilized for research, particularly of a bacteriological nature. Dr. Pugh contributes an interesting article on the general subject, but, of course, this experiment is too recent to admit of any report as yet.

### A VISIT TO THE ISLAND OF TRISTAN DA CUNHA.

We are indebted to the Medical Research Council for a copy of a communication based on a report made by Dr. E. H. Marshall, surgeon to the *Discovery*, of a visit to Tristan da Cunha during the recent voyage of that ship. The visit was made on January 30th, 1926, and lasted two days.

Dr. Marshall recalls first the history of the peopling of Tristan da Cunha. The islanders are descended from seven British men who married coloured women from St. Helena and the Cape a century ago. On only a few occasions has other blood been introduced—once when Peter William Green, a Dutchman, was shipwrecked in 1846; once in 1856 when Hagan and Rogers came to the island from America; and again when Repetto and Lavarello, Italian sailors, were shipwrecked in 1882. In recent times Robert F. Glass, head-

man of the present colony, who is a grandson of Corporal Glass, returned from the Cape with a Cape woman as his wife. The population of the island on February 1st, 1926, numbered 141 (75 males and 66 females), sixty-nine were adults, twenty-one were between the years of 14 and 21, and fifty-one under 14 years of age. Of the children under 14, twenty-three were under 4 years and four births were expected before May. There were only three persons over 80, all women, the oldest being aged 89, a remarkably well preserved woman. The oldest male on the island was aged 68. Two deaths had taken place since the island was last visited—one of a woman in December, 1925, aged 73, and one of a premature female child who lived for six days. The education of the islanders has been dependent on the efforts of clergymen, who at intervals of twenty years or so have lived on the island for periods of two to three years. It is not surprising, therefore, to find very few who can read and still fewer who can write. It has been stated that the islanders appear stupid. This has arisen through not realizing that they have a dialect of their own with a very limited vocabulary. They are extremely sensitive about their lack of education and little knowledge of English, and this constitutes an obstacle to any scheme of emigration or even temporary employment outside the island.

For trade the islanders have always depended on supplying ships with fresh meat and potatoes, in return for flour and other articles they are unable to produce themselves. Since the advent of steam and the discovery of fresh whaling and sealing grounds further south, this trade has disappeared and only an occasional sailing ship or whaler now ever calls at the island. Mr. Robert Glass stated that the domestic stock on the island consisted of cattle and sheep, some donkeys, a few pigs, and some hundreds of fowls and geese. There were 245 plots of land, varying in size from 20 to 40 yards square, planted with potatoes. The appearance of the islanders did not suggest that they were suffering from the effects of shortage of food. The men are of good physique and above the average height. The women, who work in the fields, appeared superior to the men and have a deportment reminiscent of a bygone age. Their clothes are tidy and they are cleanly in their persons. The children were quiet, well behaved, and appeared well cared for. Very few of them, and only a small percentage of the young adults, show traces of their coloured ancestry, whereas among the older inhabitants this is marked. During the visit six cases of asthma and chronic bronchitis, all of long standing, were treated. Several of the islanders complained that after ships call an epidemic of "colds" runs through the island, lasting for about three weeks. Two cases of chronic rheumatism and a few minor medical and surgical cases were seen. Robert Glass has charge of a well equipped ship's medicine chest. During the last twenty years at least the island has gained a certain notoriety by pleading for support from the outside world because of failure of the potato crop and destruction of stock during severe winters. Though hardships may have followed these calamities, it is extremely improbable that the islanders have been near starvation. It appears that fish are plentiful and easily caught, but are not popular. Hens' eggs are scarce and are consumed mostly by the wealthier families. Mollymauk eggs are taken in large quantities, and 30,000 penguin eggs are collected annually. Young mollymauks are eaten in large quantities. According to Mr. Glass 7,000 were taken during January. The islanders also go to Inaccessible Island to collect and salt these birds. It was said that cattle and sheep were mostly kept for trading purposes. As trading has practically ceased, it might be supposed that they are now more frequently consumed by the islanders. Milk is nearly always plentiful, but for long periods the islanders are without tea, coffee, and sugar. Butter, jam, and marmalade are only very occasionally available, and the inhabitants are dependent on trading for bread, as no wheat is grown. Their main source of carbohydrates is potatoes. Onions, pumpkins, turnips, carrots, beetroot, and leeks are grown, but in comparatively small quantities. It will be seen that the outstanding shortages are flour, sugar, jam, and tea. In sailing ship days there were frequent opportunities for

bartering for these commodities. Though the islanders have now almost to do without these articles, there seems no reason to think that their health has suffered. Out of 50 persons examined, only 6 admitted that they suffered from indigestion or flatulence, and these cases were of some years' standing. The Dental Committee of the Medical Research Council had suggested that if the opportunity arose the condition of the teeth of the islanders should be investigated, and just over one-third of the islanders were examined for dental caries, and the results were tabulated as follows:

*Analysis of Cases Examined.*

| Age Period:                          | 3-14. | 15-20. | 21-44. | 45-90. |
|--------------------------------------|-------|--------|--------|--------|
| Number examined ... ..               | 13    | 8      | 21     | 12     |
| Number of teeth ... ..               | 290   | 235    | 662    | 337    |
| Number of carious teeth ... ..       | 2     | 0      | 11     | 21     |
| Number of carious mouths ... ..      | 1     | 0      | 5      | 8      |
| Number of teeth missing ... ..       | 0     | 0      | 6      | 45     |
| Percentage of carious teeth ... ..   | 0.68  | 0      | 1.6    | 6.2    |
| Percentage of carious mouths ... ..  | 7.6   | 0      | 23.8   | 66.6   |
| Chronic general periodontitis ... .. | 0     | 3      | 14     | 7      |

Thus the incidence of dental caries is remarkably low, and would probably appear still lower if opportunity had presented itself to examine all the community. The teeth examined were almost without exception regular and well shaped. Although in no case did anyone admit to cleaning his or her teeth more often than once a week, and then only with finger and soap, the teeth were clean and remarkably free from salivary calculus. It is probably correct to say that the islanders, as a whole, never clean their teeth. Chronic general periodontitis was present in various stages in no less than 58.5 per cent. of those examined between the ages of 15 and 90. This is probably not a disease of recent origin in the island, since histories, dating in some cases more than twenty years back, were given of teeth becoming loose and falling out without showing signs of caries. How far a shortage of sugar and jam has prevented the spread of caries, and what influence the large consumption of potatoes, on which the islanders rely almost exclusively for their carbohydrates, has had on the incidence of chronic general periodontitis are matters for discussion.

It is evident that the population of the island is increasing. The health of the community is good and there are no signs of mental or physical degeneration due to intermarriage. There are signs that, in spite of there being no currency, property is passing into the hands of a few. For one reason or another the older islanders will never leave the island of their own free will, and the younger ones have little or no opportunity of leaving, however much they may desire to do so.

## England and Wales.

### REPORTS OF SCHOOL MEDICAL OFFICERS: LIVERPOOL AND MANCHESTER.

THE annual report of the school medical officer for Liverpool illustrates the growth and success of the work of school medical inspection and the treatment of defective children. Some difficulty is experienced in getting children to attend the clinics owing to the loss of school attendance marks, and it is stated that "the present regulations of the Board of Education dealing with this point not only hamper the work of medical treatment, but also involve the education committee in unreasonable loss of grant, and it is greatly to be hoped that this important matter will receive the very careful consideration of the Board." A great improvement in cleanliness is reported, not only in the diminution of the number infected, but also in the degree or extent of infection in those children who are not

perfectly clean. The teachers co-operate whole-heartedly in this work, and some have rendered valuable help by interviewing difficult parents. There has been a diminution in the incidence of malnutrition, but there are still far too many children undernourished or debilitated. "It must not be assumed that this is necessarily due to poverty, for many cases come from homes where this factor can be ruled out, whilst well nourished children are met with in poor homes." Of the many contributory causes improper feeding is held to be the chief. There is too much starchy food in the form of bread and potatoes, and too little fat and animal food. Fresh milk has been largely displaced by the use of tinned milk. Education is needed, and much can be done by teaching the senior boys and girls the elements of hygiene. An inquiry into vaccination showed a satisfactory percentage of vaccinated children; the unvaccinated totalled 16.3 per cent., as against about 56 per cent. for the whole of England and Wales. Among minor ailments septic sores and impetigo head the list. Ringworm has declined, and cases are readily cured by the use of x rays; only 179 are now out of school from this cause, as against 288 in the same period five years ago. Scabies continues to decline owing to the work of the cleaning stations. Tonsils and adenoids show a slight increase, so does middle-ear disease. For the treatment of the latter zinc ionization bids fair to be a real success. The amount of dental treatment given continues to increase, owing to propaganda work amongst the children and parents; there is an increased acceptance of the treatment, but there is the handicap of the loss of school marks during attendance. The incidence of stammering has been investigated; as many as 600 cases were noted, boys preponderating in the proportion of 5 to 1. So far no special classes have been formed for these children in Liverpool. One of the rare disadvantages of school treatment is shown in the record of squinting children; it is found that parents deliberately postpone treatment, knowing that this will be forthcoming when the child goes to school! It is urged that the early provision of glasses in pre-school life, with the increased chance of cure of the squint and the retention of vision, is of greater importance than operations later in school life. A special investigation of the hygienic condition of the school buildings was undertaken during the year. On the whole the report is fairly satisfactory. The worst feature is the position of the desks in the classrooms. Only 40 per cent. of the total were entirely satisfactory from the point of lighting. The older schools were the worst, and in these the desks could not be rearranged. Dealing with special schools, note is made of the success of the defective vision classes (myope classes). There is evidence of a personal contact between teacher and child, and the atmosphere of a happy family. The children are interested in their work, and the change in demeanour is marked. Antipathy to these classes is now rarely met, and parents are increasingly anxious to avail themselves of the advantages they offer. Advice is given on after-employment, and parents often regret when the period of ocular supervision is ended. "Experience confirms the view that the care and discipline learned in the classes is continued in after years, and thus materially reduced the risks of serious eye complications to which so many of these children are prone."

The annual report of the school medical officer of the sister city of Manchester gives a most dramatic chart of the progress of the work during the past ten years. The contrast with 1915 is remarkable. There has been a steady increase in the discovery of defects and in securing treatment for them. Note is made of the work of the school medical officers. The number of cases to be examined each hour has been reduced from ten to eight, as the larger number did not secure the best results. Uncleanliness has declined, so also have tuberculosis, skin diseases, and external eye diseases. The number of cases of enlarged tonsils and adenoids treated has increased, and the results have been satisfactory; the same is true of ear disease; here the detection of early cases has added to the total. Deafness was found to be cured or improved in 99 per cent. of cases. Zymotic diseases are held to be the outstanding cause of these defects. "The 'dummy' is," it is said,

"too often blamed for the condition. When a child is sucking at its 'dummy' it is obliged to breathe through the nose—and the mouth of the young is intended for suction, since all its food is taken that way." Ionization for otorrhoea has given variable results, and there has been a tendency to relapses; better results are obtained by following on at once with aural lavage, etc. Approval has been obtained for the formation of a day open-air school. There are many mentally defective children not in special schools, either because they live too far away or there is no place for them. These are examined periodically. It is very noticeable that the older these children get the less they are able to keep pace with the normal children; moreover, their instability of character and general lack of common sense render them a source of trouble and irritation in a class. There is a record of a special investigation into the "fitness of schoolboys," which is excellently worked out and of much value. Random samples of boys in a higher-grade school and an elementary school were compared. Boys in the higher-grade school showed a percentage "above normal" of 64, as against 30 in the elementary school. It is added that "the contrast possibly shows the effects of the operation of favourable and unfavourable environment, but the inherited characters of the boys also operate." The report of this investigation is worth study.

#### CITY OF CARDIFF MENTAL HOSPITAL.

In his eighteenth annual medical report, Dr. Edwin Goodall, medical superintendent of the City of Cardiff Mental Hospital, discusses the difficulties of assessing the value of inherited factors in the causation of mental disorder, excluding those in which no history was given. Heredity of some kind was elicited in 41.9 per cent. of the direct admissions during 1925, but Dr. Goodall points out that no reliable conclusions can be come to until comparative statistics are available, showing to what extent a given number of persons who have not shown mental disorder have inheritance of mental and allied disorders, in comparison with a like number who have become insane with like inheritance; obviously, a very difficult line of inquiry. Dementia paralytica accounted for 13.58 per cent. of the admissions. The number of patients discharged recovered was 74, giving a recovery rate of 40.2 per cent. Research has been carried out on the estimation of phosphorus and calcium in the blood plasma and cerebro-spinal fluid, and on the presence of porphyrin in faeces. The visiting Commissioners have expressed their satisfaction at seeing so steady an output of research and therapeutic work, affiliated in increasing extent to that of the Royal Infirmary and the University, and at observing the team work of which every new admission has the full benefit.

#### CENTENARY OF NORTH DEVON INFIRMARY, BARNSTAPLE.

On August 15th, 1826, the North Devon Infirmary opened its doors for the first time to patients, and at Barnstaple and elsewhere in North Devon 100 years later the centenary was observed as a day of rejoicing and of renewed effort. Special thanksgiving services were held in several churches in the morning, and in the evening at the War Memorial in Rock Park. Under the presidency of the first Earl Fortescue the inaugural meeting of the founders of the institution was held in March, 1824. The foundation stone of a building to contain twenty-two beds was laid in the following January, and four years after the infirmary began work a wing was added for infectious cases. The chief difficulties of the earlier years appear to have been financial or due to undisciplined patients. The importance of good ventilation and sanitation was recognized practically as early as 1841. In 1857 the drainage system was thoroughly overhauled and a good water supply obtained; from that time it is noted that baths ceased to be regarded as mere luxuries. On the death of Earl Fortescue, the first patron, in 1861, a new wing containing two wards was erected to his memory, and in 1880 Dr. Richard Budd, who had been physician to the infirmary for nearly forty years, devoted the financial testimonial presented to him on his retirement to the erection of an out-patient department, which was

opened in 1882. In the next year another wing was added and beds were endowed, while in 1889 the operating theatre was reconstructed and refurnished. The formation of the Ladies' Association in 1904 was followed by a long series of numerous valuable additions to the infirmary, including the provision of an electric lift in 1921, an x-ray installation in 1924, and a new operating table. In 1906, as part of an extensive scheme of structural alteration, sanitary towers were built, a new isolation ward was added, and the out-patient department was enlarged and improved. In 1922 the system of contributions by patients was begun, and in 1925 the lady almoner collected £555 from this source alone. In celebration of the centenary, in connexion with which a souvenir pamphlet has been issued, an appeal is being made for £10,000 to constitute a re-endowment and building fund; a sum of £7,000 has already been received. The opening of a maternity ward is proposed, and provision is to be made for the outdoor treatment of cases of surgical tuberculosis. The expenditure for 1914 was half that of 1924, but the annual income has risen from £2,838 in the first year to £5,059 in 1924. It is hoped that the present appeal will enable an additional annual income of £500 to be provided.

#### LIVERPOOL STANLEY HOSPITAL.

It was stated at the fifty-ninth annual meeting of the Liverpool Stanley Hospital that for the first time in the history of the institution the annual income had exceeded the expenditure. The Lord Mayor, who presided over the meeting, while praising the enthusiastic work of the hospital committee and the supporters of the hospital in general, said that there was still a large debit balance; during the past year, however, it had been reduced, and it was hoped that before very long it would be extinguished. In the course of the previous year the entire cost of new x-ray apparatus had been defrayed by an anonymous donor, and the London, Midland and Scottish Railway Company had given £600, a sum which it was hoped might be increased during the current year. Treatment had been given during 1925 to 1,718 in-patients and 19,757 out-patients, and there had been 67,822 out-patient attendances. Sir Benjamin Johnson referred to the steady gain in popularity which had now resulted in the Stanley Hospital being regarded as one of the leading hospitals in Liverpool.

## Scotland.

#### AFTER-EFFECTS OF ENCEPHALITIS LETHARGICA.

THE Scottish Board of Health has issued a circular dealing with the hospital treatment of persons suffering from the after-effects of encephalitis lethargica. It deals particularly with the Glasgow area, but has general reference to the whole of Scotland. The disease was made notifiable in Scotland in December, 1925, but it is noted that, while it must be regarded as infectious, the infectivity is certainly low and little is known of the way in which it is disseminated. The handling of cases in the acute stage is, on account of their relatively small numbers, well within the scope of existing infectious diseases hospitals, but a difficult problem is offered by the patients who, on account of the prolonged or permanent nature of the after-effects, tend to accumulate as subjects requiring hospital treatment. Neither hospitals for incurables nor those for infectious diseases are in a position to provide the special treatment and nursing required. A conference was held last March between representatives of local authorities and of the parish council of Glasgow to consider what action should be taken in regard to late stages of this disease. The general feeling of the meeting was that the local authorities should accept responsibility for their treatment, except in cases where the patients, on account of their mental condition, required treatment in a mental hospital. It was agreed that individual local authorities could not by themselves deal with the problem, but that if they could send their cases to a central institution they would fall in with the proposal. The parish council of Glasgow subsequently offered to make

beds in Stobhill Hospital, Glasgow, available for this purpose. About forty or fifty cases could be accommodated in a separate block at Stobhill Hospital, and the provisional terms proposed are 7s. a day, although it is pointed out that owing to the exacting demands such cases make on the time and care of nurses it may be necessary to revise this offer. All applications for the admission of cases to the hospital must be made to the Board of Health, who will decide whether the symptoms and circumstances of the patient justify his admission. All applications, therefore, must be made by or on behalf of local authorities, on a special form (to be obtained from the Board of Health), signed by the medical officer of health of the local authority concerned. The selection of cases for admission will be made primarily on the ground of domestic difficulty, and patients suffering from symptoms of the chronic Parkinsonian type—that is, who are bedridden and in need of constant attention—will receive special consideration. Any patient who, subsequent to admission to Stobhill Hospital, may be certified as insane will be removed to an asylum under arrangements to be made by the local authority by whom the case was sent to Stobhill.

#### BENEFITS OF VOLUNTARY HOSPITALS.

St. Margaret's Hospital, Auchterarder, which has been built, equipped, and endowed by Mr. A. T. Reid of Auchterarder House as a memorial to his parents, was opened on August 14th by the Duchess of Atholl, M.P. The hospital has been erected at a cost of about £10,000 and endowed with an income of approximately £1,000 a year. It stands in three acres of ground and has accommodation for fourteen beds, with operating theatre, dispensary, and other necessary adjuncts. The Duchess of Atholl, in declaring the hospital open, said that even before the war many persons had considered the days of voluntary hospitals to be numbered, and with the development of school medical services and other State responsibilities, some persons had wished the State control to be increased until no field was left for voluntary effort. These fears had increased since the war, and about the year 1920 many hospitals, especially in the south, had been in a perilous condition, from which they were saved only by a timely grant of about half a million pounds by the Government of the day. A wider recognition of the benefits that voluntary hospitals brought to the community had, however, arisen, and voluntary hospitals were now largely financed by the people for whom they were directly intended. It was a satisfaction for those who planned and gave generously to inaugurate such institutions that they are appreciated by those they were intended to benefit, and that these persons gave readily for their support. Voluntaryism to-day was stronger than many would have thought possible ten or fifteen years ago. While the recognition of responsibility by the State and by local authorities in the matter of health was welcomed, the community felt that any deterioration in the strong element of voluntaryism, which had been a part of Anglo-Saxon society, would be an impoverishment of national character. One great need that would be met by the founding of the new hospital was prompt surgical aid in cases of accident, which were nowadays more numerous than formerly. In other ways it would prove an inestimable boon to people in the surrounding parishes who needed institutional treatment, and who preferred to have that treatment under their own medical practitioner. Lord Haldane proposed a vote of thanks to the Duchess of Atholl.

#### TEACHING THE DEAF.

At the 116th annual meeting of the Edinburgh Royal Institution for the Education of Deaf and Dumb Children, a demonstration of teaching methods was given in the gymnasium of the institution, and Mr. Barker, the headmaster, explained that there were two methods of teaching the deaf, both of which were employed in this school. These were the speech method and the method in which the language of finger signs was used. In dancing even the youngest pupils developed the sense of rhythm which hearing children acquired by the ear. The chairman, in moving the adoption of the report, said that recent inven-

tions like the telephone, the gramophone, and wireless telegraphy seemed to widen the gulf between normal persons and those whose organs of speech and hearing were impaired. It was interesting to recall that Graham Bell, famous as the inventor of the first telephone, was also famous for the improvement he introduced into the teaching of the deaf and dumb. This teaching was now producing remarkable results. He referred to the great praise which had been pronounced by the Scottish Education Department upon the admirable way in which this teaching was conducted, and he warmly congratulated the headmaster and staff. He referred also to the fact that a very large percentage of old pupils of the institution were now wage-earners. It was well that great attention was paid to the physical development of the pupils, and an interscholastic blue ribbon, the Lindsay swimming cup, had this year been carried off by this institution. It had not yet been sufficiently recognized by parents and education authorities that it was extremely important that the education of the deaf child should be begun at a very early age—if possible, during infancy. In conclusion, he appealed to the public for increased financial support.

#### EDINBURGH CLINIC FOR SURGICAL TUBERCULOSIS.

In connexion with the Municipal Tuberculosis Scheme, Dr. William Robertson, M.O.H. for Edinburgh, has issued a circular stating that an additional clinic for cases of surgical tuberculosis has been instituted at the Royal Victoria Dispensary. This clinic will be held on Wednesday afternoons at 3 o'clock, and medical practitioners are invited to avail themselves of the opportunity to send any cases in which advice and suitable treatment are required. It is intended shortly to install ultra-violet ray lamps at this centre for the purpose of making this form of treatment available to out-patients for whom it may seem desirable.

## Ireland.

#### THE FREE STATE CENSUS OF 1926.

THE Free State census of 1926 records a decrease of 166,886 (5.3 per cent.) in the population of the twenty-six counties during the fifteen years beginning April 2nd, 1911, and ending April 18th, 1926. The salient points of the report issued by the Director of Statistics show that since April 2nd, 1911, the population of all Ireland decreased from 4,390,219 to 4,229,124—161,095, or 3.7 per cent.; Free State decreased from 3,139,688 to 2,972,802—166,886, or 5.3 per cent.; Northern Ireland increased from 1,250,351 to 1,256,322—5,791, or 0.5 per cent. There were 1,506,916 males and 1,465,886 females in the Free State as compared with 1,589,509 males and 1,550,179 females in 1911. There are 973 females to every 1,000 males in the Saorstát to-day, whereas in Northern Ireland there are 1,066 females to every 1,000 males. In Ireland as a whole there are 999 women to every 1,000 men. The political changes in the last intercensal period (resulting in particular in the withdrawal of British military forces), and the deaths of Irish soldiers in the European war, tended to retard the decline of the female-male ratio. In Dublin, as in other cities, the female population exceeds the male, while in the country districts and small towns there is a male excess. A disturbing, but hardly unexpected, feature of the census is the consistent movement of population to the towns. In 1841 the town population of the Free State was 1,266,324. In 1861 a decline set in, and continued until 1891, when the movement towards the towns began anew. In 1891 the town population was 1,053,757; to-day it is 1,095,188, while the country population during that period has fallen from 2,154,848 to 1,877,614. One of the most remarkable decreases has been in what the returns describe as the country population of the Free State. The total number of this class of resident in the year 1841 was 5,281,328; since then it has steadily decreased, and has now been reduced to 1,877,614. The town population in the same period has decreased by only 171,136 persons, but as compared with the 1911 figures shows an increase of 28,213, the total in 1926 being 1,095,188. The figures for

Dublin city and the four adjoining urban districts are 419,156, which, compared with 1911, is an increase of 21,559, and with 1901 an increase of 44,021. The most recent censuses (all in 1920 or 1921) of the countries to which the people of Ireland emigrate in the largest numbers throw a valuable light on Irish emigration. To illustrate the large number of Irish-born persons living in other countries it may be mentioned that there were 1,037,234 such persons living in the United States, and 367,747 in England and Wales; altogether the number of Irish-born persons living in other countries is no less than 43 per cent. of the population of Ireland in 1926, a proportion which makes Ireland unique amongst the countries of the world. This exiled population must in itself attract a large number of emigrants, relatives and friends of the exiles, every year, no matter how prosperous conditions are in Ireland.

## Correspondence.

### MINER'S NYSTAGMUS.

SIR,—The letters on the subject of miner's nystagmus which have appeared in your issues of August 14th (p. 323) and August 21st (p. 361), from the pens of Dr. Vernon and Mr. A. S. Percival respectively have been of special interest to me. I venture to think that the defective illumination theory of the causation of miner's nystagmus has entirely broken down; as a corollary of that opinion, I think that the whole subject must be reinvestigated. My reasons for that view are given in various publications, particularly in the *Lancet*, May 23rd, 1925, the *Glasgow Medical Journal*, March, 1926, and in the *Transactions of the Institution of Mining Engineers*, vol. lxxi. The last mentioned contains, not only my paper, but also a very full discussion of the subject. To these publications I would respectfully call the attention of Dr. Vernon.

My reason for intruding at the present moment is once more to point out that coal-mining does not require macular vision at all, nor, in my opinion, does almost any other form of manual work. So far back as the meeting of the British Medical Association in Toronto (1906) I called attention to the fact that miners who have high degrees of myopia, say between ten and twenty diopters, are in no way inconvenienced thereby in their work. With ten diopters the remote point of macular vision is approximately at four inches, and with twenty diopters it is approximately at two. Now miners with such high errors of refraction can mine coal quite easily and that without bringing their faces to four or to two inches from the coal surface.

The important visual factors in coal-mining are (a) field vision, (b) alignment, (c) actual distance. There is this peculiarity about field vision, that its usefulness does not, to any extent, depend on the correction of errors of refraction. A man with a high myopia is quite capable of seeing a tramcar at a very considerable distance. If a would-be traveller, with four diopters of myopia, had to bring his face to within ten inches of the car before he saw it, then, for him, travelling would be an impossibility. The same remark holds true in navigational matters, as I showed many years ago in the *Liverpool Journal of Commerce*. A man on the look-out with three or four diopters of myopia—an amount which would, even in health, reduce his vision to about 6/60—is as competent as an emmetrope to pick up objects at sea, always provided that, apart from the myopia, the visual apparatus is perfectly healthy.

The question of alignment is very important; a simple experiment will illustrate its function. I take two small coins (shillings or halfpennies) and place one of them to be used as a fixation object on a table. The other is placed on the same table at a considerable distance from the first. I now find that while I look steadily and constantly at the first I can, at any time, without any difficulty strike the other with my outstretched hand or with a stick if the distance be too great. That roughly illustrates what I mean by alignment, and further proves that macular vision is not required to strike an object eccentrically placed in the field of vision.

Another illustration of the same thing is seen in the use of a sledge-hammer. The hammerman cannot with his

macular vision fix the object which he is going to strike for the violent movements of his body prevent him doing so.

I have elsewhere discussed the estimation of distance ("Psychology of vision," *Glasgow Medical Journal*, 1921), and therefore will not prolong this letter: I only wish to repeat that manual work, including coal-mining, does not involve visual acuteness in the ordinary acceptance of that term, but it does involve field vision, proper alignment, and the estimation of distance.—I am, etc.,

Glasgow, Aug. 23rd.

FREELAND FERGUS.

SIR,—With reference to the discussion now taking place in your columns on the subject of the etiology of miner's nystagmus, may I point out that the late Dr. W. H. R. Rivers in 1920 was firmly of the opinion that the disorder was psychogenetically determined, that it was, in fact, an occupation psychoneurosis?

At his instance I was appointed to investigate the psychological aspects of the disorder under the direction of the Medical Research Council. My findings were summarized in a short paper, "The psychoneurotic aspects of miner's nystagmus" in the *Journal of Medical Psychology* (1923), and, in greater detail, in "The mental factor in miner's nystagmus" in the *Journal of Mental Science* (April, 1926).—I am, etc.,

H. WILFRED EDDISON, M.B., D.P.M.

Epsom, Aug. 23rd.

### OBSTRUCTION AT THE VESICAL OUTLET AFTER PROSTATECTOMY.

SIR,—In reply to Mr. Irwin's letter (August 14th, p. 324) he and I must agree to differ on the subject of perurethral diathermy in the treatment of certain fibrous types of prostatic enlargement.

I make it a practice to follow up all cases of prostatectomy, using the cystoscope to anticipate any possibility of post-operative obstruction. Where this is not done, but the patient is still able to micturate naturally, it is sometimes difficult, but not impossible, to find an opening, providing an operating urethroscope is used. The early stages of dilatation can then be effected either by the passage of a small expanding dilator (see Canny Ryall, *Operative Cystoscopy*, p. 43 et seq.) or of a guide, to which successive sizes of followers can be screwed after withdrawal of the urethroscope. The passage of the Kollmann's dilator should then present no difficulties, and both this and the treatment mentioned above can be painlessly employed providing efficient local anaesthesia is secured. I have at the moment two patients under my care in whom the curved Kollmann's dilator is being used at weekly intervals and who both continue to attend regularly.

Routine packing of the prostatic cavity is too widely employed to warrant discussion, and serves the double purpose of controlling post-operative haemorrhage and minimizing the possibility of obstruction. These, in my opinion, outweigh other less possible dangers to the patient, the attendant discomfort yielding readily to suitable drugs.—I am, etc.,

J. C. AINSWORTH-DAVIS, M.B., F.R.C.S.E.

London, W.I., Aug. 20th.

SIR,—In Mr. Irwin's reply to Mr. Ainsworth-Davis on urethral obstruction following suprapubic prostatectomy, he states that "in these cases it is sometimes impossible to find an opening at all, and frequently difficult to get a fine bougie through." With this I entirely disagree, for with a suitable urethroscope the opening into the bladder can always be seen, and can be enlarged by operating through the urethroscope. The instruments available for perurethrosopic operations are many and varied, and include bougies, knife, scissors, expanding dilators, and the diathermy electrode. Local anaesthesia suffices in these cases for painless operation. Subsequent treatment consists in the weekly passing of graduated steel bougies, or the efficient use of a Kollmann's dilator. In these days it should seldom be necessary to reopen a bladder in order to treat a stricture which is a direct consequence of prostatectomy. Mr. Irwin also refers in disparaging

terms to the routine use of packing the prostatic cavity. Personally my routine is to pack for twenty-four hours, after which the bladder is irrigated daily by the Janet method, and steel bougies are passed once or twice in the third week. Most patients on whom I have operated for enlargement of the prostate attend my clinic for urethroscopy at intervals of three months, and I find that instances of post-operative stricture are so rare and so easily treated that I seldom feel that it would have been to the patient's advantage to have been subjected to the Thompson-Walker modification of Freyer's suprapubic prostatectomy.—I am, etc.,

London, W.1, Aug. 21st.

F. McG. LOUGHNANE.

#### RECOVERY AFTER MASSAGE OF THE HEART.

SIR,—In the JOURNAL of August 21st (p. 342) Mr. R. M. Glover makes reference to a letter of mine (BRITISH MEDICAL JOURNAL, May 22nd, 1926) commenting on a contribution of Mr. Girling Ball's under the above heading: may I be allowed a few words in reply?

Everyone interested in the problem of resuscitation will welcome Mr. Glover's letter. It supplies just the information needed, in this case the proof, that massage of the heart alone may suffice to restart the heart, after the failure of other physical means (change of posture, tongue-traction, hot applications, artificial respiration), applied for several minutes. His letter therefore reinforces the evidence in favour of the value of heart massage, but it does not invalidate my criticism that in Mr. Girling Ball's case another agency which had been introduced, adrenaline, might have been itself the *causa causans*, or, failing that, a *causa contribuens*. For exactly the same kind of evidence which Mr. Glover brings forward is advanced by Dr. Carl Bodon (*Lancet*, March 24th, 1923) to prove that adrenaline alone, injected directly into the heart, may suffice to restore the heart's action. His case went on to complete recovery.

In respect, then, of these two remedies, honours seem to be easy, with perhaps a slight advantage in favour of the chemical stimulant, as yielding a quicker cardiac response (half a minute as against two minutes), and as being more rapidly applicable.

The conclusion to be drawn, in my opinion, is that adrenaline in 1 c.cm. ampoules should always be in readiness in the operating theatre and the ward, and should be injected at once, as a first act, in such cases; and that failing response within, say, two minutes the surgeon should have recourse to heart massage.—I am, etc.,

London, W.1, Aug. 21st.

HARRINGTON SAINSBURY.

#### MILK AS A GROWTH STIMULANT.

SIR,—Referring to the mention in your issue of August 14th (pp. 312 and 317) of the increase of weight in school-boys of 7 to 12 years of age by a daily pint of milk, it is interesting to speculate whether any advantage ultimately accrued to them from the increased rate of development during these ages. Certainly the increase would be artificial, as our remote ancestors would not have had these opportunities in the early times when the genus was developing, and the question arises as to whether the human or other mammal can be ultimately increased in size by better feeding than the average.

Horsekeepers believe that a well fed colt will eventually be bigger because he grows faster than a badly fed colt, but I do not think there is any real evidence to this effect. The object in the case of thoroughbreds is to race them when they are mere babies of 2 years old, but it is doubtful when they are mature if they are any the better for it.

Again, there is the question when and how the hypophysis and the other glands regulating growth cease their action, whether time is the essence of the effect produced, whether their action is for a definite time or a definite amount of growth, and whether better or worse nutrition eventually makes any difference in the size of the mature animal.

It would be interesting to have any evidence on this score, as it has an important bearing on the general desire to force on the growth of the young animal.—I am, etc.,

Exeter, Aug. 20th.

SHEFFIELD NEAVE.

#### THE LIVERPOOL CANCER RESEARCH ORGANIZATION.

SIR,—We propose to hold in Liverpool clinics and demonstrations of the methods employed by us in the treatment of malignant disease for clinical pathologists attached to clinics and hospitals of standing, in order that they may have the opportunity of studying at first hand the details of this work.

Subsequently "choriotrope" will be obtainable for use in the treatment of the patients of those who are attached to the clinics concerned. It is suggested that the clinical pathologists who attend the demonstrations make themselves responsible for the full and proper conduct of the examinations required in every case subsequently treated under their guidance, and that no publication regarding results be published for, say, three years.

It must be understood that the entire clinical staff of the Liverpool Cancer Research Organization is on a part-time basis, and, therefore, that members cannot place themselves entirely at the disposal of those attending, nor can these demonstrations be repeated except at long intervals, and then only to limited numbers. Consequently it may be necessary for a selection to be made from those applying if there be too many at one time. A certain number of invitations have been issued to those who have already expressed a desire to attend; but a few further applications are now invited.

The demonstrations will be chiefly conducted by Dr. Leslie Cunningham, assistant director of the Organization, and will commence at 10 a.m. on Monday, September 6th; and continue until Wednesday, September 15th.—I am, etc.,

Liverpool, Aug. 20th.

W. BLAIR BELL.

#### THE FUNCTION OF THE SPLEEN.

SIR,—In the interesting annotation on the function of the spleen in your issue of August 21st (p. 352) it seems to me that the terms *hypotonic* and *hypertonic* are rather loosely used, as illustrated in the following sentences:

"It is therefore concluded that the blood of the spleen is a selected blood, and that it is less resistant to hypotonic solutions. When haemolysed by saponins the blood of the spleen is more resistant than the cells of the general circulation. From other observations it is inferred that the lessened resistance to hypertonicity and the greater resistance to saponins are due to a smaller content of phosphoric acid."

In hypotonic and hypertonic solutions, so far as the red cells are concerned, the osmotic current is reversed, and when they were haemolysed, by whatever agent, I should have thought that their resistance would have disappeared.

It is, or should be, well known that concussion of the sixth and seventh cervical spines dilates the spleen, and concussion of the second lumbar vertebra contracts it. The late Albert Abrams used these manipulations in the treatment of many infectious diseases by what he termed "splenic sterilization."—I am, etc.,

JAMES BARR.

Liverpool, Aug. 21st.

#### MEDICAL DEFENCE.

SIR,—This matter cannot be left in the position in which it emerged from the Annual Representative Meeting.

The result of the discussion is a little baffling. A resolution was tabled from the North of England Branch urging a complete and comprehensive cover of the legal liabilities of a doctor arising from the practice of his profession. A speaker on behalf of the English defence societies declared that the societies would not give such a cover, whereupon the mover of the resolution "expressed himself quite satisfied, and leave was given to withdraw the motion."

This result will not be satisfactory to the North of England Branch and those of us who have been urging the matter on the societies for the last twelve months. Little more than a year ago we thought that all our burdens would be borne by the society to which we belonged. This fond hope was shattered by the report of the solicitor to the Medical Defence Union, Limited, in its last published annual report.

It will be well to emphasize again the limits of the protection afforded by the English societies.

1. A member of either society may be covered for his own acts or omissions.
2. A member of either society may be covered for the acts or omissions of his assistant, locumtenent, house-surgeon, or other subordinate medical officer who is also a member of either society.
3. A member of the Medical Defence Union, Limited, may be covered for the acts or omissions of his locumtenent who is not a member of either society.
4. A member of the London and Counties Medical Protection Society, Limited, will not be covered for the acts or omissions of his locumtenent who is not a member of either society.
5. A member of either society will not be covered for the act or omission of an assistant, house-surgeon, or other subordinate medical officer who is not a member of either society.
6. A member of either society will not be covered for the acts or omissions of a nurse or other lay person acting on his instructions.

The word "may" has been used in tabulating the cases where a cover is afforded to emphasize a further point. Even when a case comes within this classification, after it has been qualified as a case which may be considered, there is no compulsion on the society to take up the case and defend it. The council reserves the right to take up or refuse to take up any case. Whether a member is protected or not depends on the vagaries of a committee meeting.

We are told that all the societies undertook was to defend members who are unjustly attacked, and that this was interpreted in a liberal and sympathetic manner.

Let us see how this works out in practice, remembering that the basis for action is the "unjust attack." Suppose that a certain member is threatened with an action at law because of the act of an assistant. We will further suppose that the threatened action is the most unjust that the malignity of a cantankerous patient can devise. It is quite obvious that the injustice of the action has no relation whatever to the fact of the membership or otherwise of the assistant of a defence society. Yet that is the determining factor in the case. If the assistant is also a member the society will defend the unjust action; if the assistant is not a member the society will not defend the member against the unjust attack. Judged by their own standards the societies fail in their objects and pretensions. Further, we are not asking for "liberal and sympathetic treatment." We ask for a complete protection for our legal liabilities; we are willing to pay for it, and we require that it will be a "right" and not a "privilege," free from disabling provisions and exceptions.

I have heard that the English societies say they do not intend to do this, that it is impossible, and that it will mean a prohibitive subscription. Yet the letter from the Scottish society in your issue of August 7th says they have always given this cover for assistants, etc., for the ordinary subscription. Are we to assume that what is possible in Scotland is impossible in England?

I have before me now the cover note of an insurance society promising cover

"Against all third party risks incurred in the practice of the insured's profession, including prescribing, dispensing, advice to patients, and including law costs"

for the modest sum of twenty shillings for one year.

If the English societies have spoken their last word they have clearly outlived their usefulness, and have failed to march with the necessities of the times. This matter cannot be dropped. There is too much involved in it for every practitioner. The general public is becoming more and more used to reports of doctors being sued for various alleged offences. They are becoming aware of the harm they can do a doctor even by an abortive action. The disciplinary procedure of the National Health Insurance Acts is training the public in the art of discovering the weak places in our armour and in the art of framing and sustaining complaints. We ourselves stress the point of the patient's rights in these matters in all our discussions with the Ministry of Health on the question of discipline. This matter has reached such dimensions, and the risks run by all of us are so great, that a complete protection must

be found. If the old defence societies fail us we can only look to the British Medical Association.—I am, etc.,

R. H. DIX,

Honorary Secretary, Sunderland Division,  
British Medical Association.

August 22nd.

#### DEFENCE OF ASSISTANTS AND LOCUMTENENTS.

SIR,—Dr. E. Farquhar Murray, in his letter in your issue of August 14th, complains that no reciprocal arrangement was made between the two other societies and the Medical and Dental Defence Union of Scotland. This was simply due to the fact that no new arrangement was required as far as the Scottish society was concerned. In stating that the London and Counties Medical Protection Society makes no statement on the protection of members in respect of locumtenents, Dr. Murray has evidently not seen my letter which appeared in your issue of April 17th, in which it is explained that this society has for many years protected, and still does protect, its members in respect of locumtenents.

The essential difference between a locumtenent and an assistant is that the locumtenent acts *in loco principalis*, and cannot possibly be controlled or guided by the principal, whereas the assistant is often acting under the instructions of his principal, and to some extent under his control and guidance.

The various circumstances in which qualified practitioners undertake locumtenency does not much affect the legal position as regards their principals. Dr. Murray can rest assured that it is in the interests of the above societies to give the fullest protection they can to their members, as they have really no interest apart from their members.—I am, etc.,

HUGH WOODS,

General Secretary, London and Counties  
Medical Protection Society, Ltd.

Victory House, Leicester Square,  
London, W.C.2, Aug. 20th.

#### WEEDS, CANCER, AND ACIDITY.

SIR,—In connexion with my golf course construction work, I pointed out many years ago that weeds such as plantains, daisies, etc., will not germinate in acid soil, and quite recently the Scientific Advisory Committee of the United States Golf Association have gone into the subject very much more thoroughly and have made many experiments regarding the exact degree of acidity of soils which prevents the growth of these weeds. There is quite a simple test which estimates the exact degree of alkalinity or acidity of soil.

Since reading an account of the interesting investigations of an Indian professor (whose name I have forgotten) on the similarity between plant and animal life, described by him to the British Association, I thought it possible that cancerous growths might flourish under similar conditions to weeds in soil. There must be some determining factor that causes cancer development in one individual and not in others who live under apparently similar conditions and have been in similar contact with the cancerous germ, if there is one.

In regard to plants, roses flourish in alkaline soil, rhododendrons, gorse, heather, and fir trees in acid. Rye grasses, cocksfoot, plantains, daisies, etc., flourish in sweet or slightly acid soil, whereas the finer bent and fescue grasses require very acid conditions, and if you obtain a certain degree of acidity you get a complete freedom from plantains, daisies, clover, and so on.

Might not the degree of acidity or alkalinity of the blood and tissues be also the determining factor in the growth of cancer? If this is so, there should be no great difficulty in altering the acidity or alkalinity of the human tissues and preventing the growth of the disease.

During the last hundred years much thought has been spent and thousands of experiments made regarding the growth of weeds, and investigations have been made into the minutest details of the chemical composition and physical characteristics of soil, and finally it turns out that the solution is an extremely simple one; may not the cause and treatment of cancer be equally simple?—I am, etc.,

Moor Allerton Lodge, Leeds, Aug. 23rd.

A. MACKENZIE.

## Obituary.

## D. EDGAR FLINN, F.R.C.S.I.,

Late Medical Member, General Prisons Board, Ireland.

COLONEL D. EDGAR FLINN, F.R.C.S.I., M.R.C.P.I., died on August 18th at Dun Loughaire, co. Dublin, aged 76. He was a son of Mr. D. E. Flinn of Buenos Aires. He received his early education at the Jesuits' School at Clongowes, and his medical courses were attended at the Royal College of Surgeons, Ireland. Colonel Flinn served for twenty years in the Territorial Forces, retiring with the rank of colonel. From 1875 to 1882 he was medical officer of health in East Staffordshire. From 1895 to 1910 he was a medical inspector of the Local Government Board in Ireland, and he was then appointed medical member of the Irish Prisons Board and chief inspector of reformatories and industrial schools; he retired in 1917, and was succeeded by Dr. C. J. MacCormack. He was a member of the Viceregal Commission to inquire into the high death rate in Belfast in 1907, and of the Dublin Typhoid Fever Committee of Inquiry; he edited the *Health Record* (1890-94), and was for ten years examiner for the D.P.H. of the Royal Colleges of Physicians and Surgeons, Ireland. He was a member of the council of the Royal College of Surgeons in Ireland, Fellow of the Royal Sanitary Institute, and was president of the State Medicine Section of the Academy of Medicine in Ireland, 1894-95. He was well known in the west of Ireland, where he served through two periods for the relief of distress under the Poor Law Relief Acts in 1895-96, following a failure of the potato crop. He was the author of *Wintering Stations in Ireland*, *Rural Water Supplies in Ireland*, *The Public Cleansing of Towns*, *Irish Health Resorts*, *The Administration of the Public Health Act in Ireland*, and many contributions to medical journals.

Dr. FRANCIS JAMES MCARDLE, who died recently at Durham, aged 65, was educated at University College, Liverpool, and at Newcastle-upon-Tyne, where he obtained the diploma L.R.C.P.I. in 1887. After serving as an assistant to the late Dr. Slater of Newcastle he removed to Durham in 1888, when he succeeded the late Dr. Wild of Gillesgate, and built up a very large practice. Dr. McArdle took great interest in municipal affairs, and was for some years a member of the Durham City Council; he later became a school medical officer. He was a member of the Durham Division of the British Medical Association. Some four years ago his health became seriously impaired, and since last September he had been almost bedridden.

The death occurred on August 16th, at his residence at Burntisland, of Dr. GEORGE WIGHT; he had been in bad health for some months. Dr. Wight graduated at Edinburgh University in 1903, and took the diploma in public health in 1905. He was for over twenty years in general practice in Burntisland, and had been medical officer of health for the burgh since 1910. During the war Dr. Wight served as a captain in the R.A.M.C., and saw a considerable amount of service on the eastern front. He was 45 years of age, and is survived by a wife and two sons.

The following well known foreign medical men have recently died: Dr. C. ODDO, professor of clinical medicine at the medical school of Marseilles; Dr. A. COL, professor of materia medica at the medical school of Nantes; Dr. HENSEVAL, professor of hygiene and bacteriology at Ghent University; Dr. GEORGES POJAT of Paris, one of the pioneers of French laryngology and a founder of the *Bulletin Médical*; Dr. NICAY of Vichy, director of the *Journal de médecine de Paris*; and Dr. WILHELM AUTENRIETH, inventor of a colorimeter and professor of medical and pharmaceutical chemistry at Freiburg University.

## The Services.

## DEATHS IN THE SERVICES.

WITH regret we record the death, suddenly, on July 26th, of Lieut.-Colonel Rochford Noel Hunt, D.S.O., R.A.M.C., at the age of 53. He was born on December 7th, 1872, and was educated at the University of Dublin, where he took the degrees of M.B. and B.Ch. in 1900. He was commissioned lieutenant in November, 1900, became captain in 1903, major in 1912, and lieutenant-colonel in 1923. During the war he commanded the hospital ship *Accrass*, No. 135 Field Ambulance, No. 7 and No. 42 Casualty Clearing Stations, and No. 35 General Hospital, the latter for over four years. He saw service in Egypt and France. He was twice mentioned in dispatches in 1917, was awarded the D.S.O. in 1918, and in 1919 was the recipient of the Médaille des épidémies (Vermeil), France. Heart trouble caused him to be placed on the half-pay list and ultimately to retire on retired pay on November 23rd, 1925.

Fleet Surgeon John Black Nicoll, R.N.(ret.), died in Edinburgh on July 11th, aged 87. He was educated at the University in that city, where he graduated M.D. as long ago as 1860; he took the L.R.C.S.Ed. in the same year. He entered the navy soon after, and attained the rank of fleet surgeon in July, 1882.

## Universities and Colleges.

## SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

**SURGERY**.—A. K. A. Carter, M. E. M. Carter, C. E. Nicholas, J. Pattis, A. Purvis, M. Stinnesbeck, N. W. Wood.  
**MEDICINE**.—J. Dywien, R. C. Glover, K. G. B. McMahon, T. C. Pain, P. H. Row, L. Schapera, R. S. S. Smith, J. A. H. Sykes, L. D. Williams.  
**FORENSIC MEDICINE**.—N. H. Allen, F. W. Barton, S. B. Brownling, M. E. M. Carter, F. G. Hardaker, C. E. Nicholas, K. Roberts, L. D. Williams, N. W. Wood.  
**MIDWIFERY**.—C. B. Ball, A. Henkamp, W. Hinds, S. Jenkinson, H. S. Littlepage, J. B. Lurie, A. Purvis, R. I. Richards, T. W. Riseley, J. M. F. Whitby.

The diploma of the Society has been granted to Messrs. N. H. Allen, C. B. Ball, A. K. A. Carter, W. Hinds, J. B. Lurie, K. G. B. McMahon, T. C. Pain, A. Purvis, P. H. Row, L. Schapera, M. Stinnesbeck, J. A. H. Sykes, and J. M. F. Whitby.

## Medical News.

DR. L. R. YEALLAND will open a discussion on seizures, on Wednesday, September 1st, at 9 p.m., at the Post-Graduate Hostel (Imperial Hotel, Russell Square, W.C.1), and on Friday, September 3rd, at the same hour, Dr. A. L. Gregg will deal with the sigmoidoscope in diagnosis; medical practitioners are cordially invited. On August 17th, with Dr. Long of Oklahoma in the chair, Dr. Donald Armour, introducing a discussion on head injuries, recommended an ipsilateral decompression in all cases of compression due to injuries; even the symptoms following contrecoup often yielded to it. Lumbar puncture was valuable in treating traumatic neuroses, but was dangerous in the presence of high intracranial pressure due to the possible formation of a "pressure cone." Trephining for decompression should be large. On August 19th Dr. Harold Scott, pathologist to the London Zoological Society, opened a discussion on tuberculosis among wild animals in captivity, with Dr. Simpson Wells of Cape-town in the chair. The symptoms of the disease varied in animals, birds, and reptiles, but was nevertheless intercommunicable.

THE Fellowship of Medicine announces that each week at the City of London Maternity Hospital there will be a course in obstetrics, including ante- and post-natal clinics and children's welfare clinics; application to attend should be addressed to the Fellowship. During September courses will be arranged as follows: a daily afternoon course at the Central London Ophthalmic Hospital from September 6th to October 2nd; lecture demonstrations at the Bethlehem Royal Hospital on Tuesdays and Saturdays, at 11 a.m., from September 7th to October 2nd; an afternoon course at the Infants Hospital, from September 13th to 25th; four lecture demonstrations by Dr. Heald at the Royal Free Hospital, on treatment by electrotherapy, on successive Wednesdays, at 5.15 p.m., beginning on September 22nd; a comprehensive course in orthopaedics at the Royal National Orthopaedic Hospital, from September 20th to October 2nd; and an all-day intensive course in medicine, surgery, and the specialties at the Westminster Hospital, from September 20th to October 2nd. Copies of all syllabuses, the general course programme, and the Fellowship journal may be obtained from the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

THE annual dinner of the past and present students of the Westminster Hospital Medical School will take place at Gatti's Restaurant, Strand, W.C., on Friday, October 1st; the chair will be taken by Mr. William Turner, M.S., F.R.C.S., at 7 p.m.

UNDER the auspices of the Smoke Abatement League of Great Britain an exhibition will be held at Bingley Hall, Birmingham, from September 6th to 18th, to demonstrate recent scientific advances towards the elimination of the polluting substances emitted from the chimneys of factories and houses. The Public Health (Smoke Abatement) Bill introduced by the Ministry of Health has already passed through the House of Lords, and has been read a second time in the House of Commons. The exhibits will include a large industrial boiler-house believed to be almost perfect from the point of view of efficiency, fuel economy, labour-saving, and the elimination of smoke; an electric furnace for hardening and annealing pen nibs; a domestic section, with demonstrations of coal grates which consume their own smoke; smokeless fuel; central heating; panel heating; and the latest improvements in the application of gas, electricity, and oil for producing power.

THE President of the Board of Trade has appointed a standing committee to consider questions connected with the economic use of fuels and their conversion into various forms of energy. It seems reasonable to hope that the inquiries of this committee, of which Sir Alfred Mond, M.P., is chairman, may eventually result in recommendations which will diminish the smoke nuisance.

THE KING has granted authority to Dr. Clermont Grantham-Hill, Medical Inspector to the Sudan Government, to wear the decoration of the insignia of the Fourth Class of the Order of the Nile conferred upon him by the King of Egypt in recognition of valuable services rendered.

THE second general report of the People's League of Health covers the years 1922 to 1925. The object of the league is stated to be "the raising of the standard of health of the British Empire," and in its pursuit the league is involved in many activities. It endeavours to create an enlightened public opinion to support legislation which medical and other scientific men regard as necessary to the national health. It publishes statistics relating to the low standard of health in this country. It sends deputations to the Minister of Health to urge the adoption of health measures. In May, 1924, it held a conference at the British Empire Exhibition on "the latest knowledge regarding the causes, treatment, and prevention of disease." Lectures have been given at various centres and in prisons and Borstal institutions. The league has also awarded six travelling scholarships to enable the winners to visit for a short period foreign countries and to observe the health work done in those countries. The outstanding feature of the People's League of Health is the large and comprehensive Medical Council which supports and advises on its objects.

THE American Medical Association has issued the thirty-seventh edition of its abstract of laws and rulings regulating the practice of medicine in the several States and territories of the United States. The new edition had become necessary owing to the many changes made recently in the medical practice Acts, and the information now given is correct, so far as can be learned, down to June, 1926. In the latter half of the volume information is given about foreign medical schools, and about medical registration and practice in foreign countries. To judge from the two pages devoted to medical education in Great Britain, the information collected by the Council on Medical Education and Hospitals of the Association is reliable and correct.

DR. WALDO, coroner for the City of London and Southwark, in his report for 1925 states that 512 inquiries were held and that post-mortem examinations were ordered and carried out in all inquests of death with the exception of 18. Among the cases were 27 of suicide, 158 due to accident, and 94 to natural causes. Of the deaths due to accident 63 were caused by road vehicles—namely, 23 by motor vans, 14 by motor omnibuses, 3 by trams, 3 by charabancs, 3 by taxicabs, and 6 by motor cars and horsed vehicles; 11 pedal cyclists were killed by collisions with vehicles of various kinds. Dr. Waldo considers it a defect in the Coroners (Amendment) Bill that it does not contain a provision for the appointment of deputy coroners in districts where this cannot now be done. The worst blot in the bill, however, he thinks is that Clause 21 gives power to a coroner to order a medical practitioner to make a post-mortem examination and to dispense with a public inquest in certain cases. He considers that if a post-mortem examination is necessary an inquest also is necessary.

AT an inquest held at Nunceaton last week with regard to the death of a man, aged 52, after taking a dose of "Indian brandy," the druggist's wife informed the coroner that this was a well known preparation consisting of one part tincture

of capsicum, three parts tincture of rhubarb, and four parts spirits of nitre, and that there was no recognized dose. A post-mortem examination was performed and medical evidence was to the effect that death was due to perforation of a gastric ulcer after swallowing a mixture containing capsicum. A verdict of death from misadventure was returned.

MESSRS. LIPPINCOTT have in the press a new edition of the *United States Dispensatory*, edited by Dr. H. C. Wood, professor of pharmacology and therapeutics in the University of Pennsylvania, Dr. C. H. Lewall, dean of the Philadelphia College of Pharmacy, and Dr. H. H. Younken, professor of botany in the Massachusetts College of Pharmacy. This is the twenty-first edition and will contain about 2,000 pages. It purports to deal with all drugs and preparations of the latest United States and British *Pharmacopoeias*, and contains particulars about a large number of unofficial drugs.

THE late Dr. Ernest Septimus Reynolds, Emeritus Professor of Clinical Medicine in the University of Manchester, has left estate of the gross value of £30,183 with net personality £28,180. He has bequeathed £1,000 to the Manchester Royal Infirmary to endow a bed in memory of his work in that institution.

THE seventh annual report of the Ministry of Health (1925-26) has been published by H.M. Stationery Office, and can be obtained from it, or through any of its branches, or from any bookseller (price 3s. 6d.). The subjects dealt with in it fall under the main heads of public health, local government and local finance, poor law, national health insurance, and contributory pensions. There is a separate section on the work of the Welsh Board of Health. Most of the matters treated in it have been dealt with in official publications noticed by us on various occasions during the year.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *BRITISH MEDICAL JOURNAL* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *BRITISH MEDICAL JOURNAL* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *JOURNAL*, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the *BRITISH MEDICAL JOURNAL* are *MUSEUM* 9561, 9562, 9563, and 9564 (internal exchange, four lines).

THE TELEGRAPHIC ADDRESSES are:

**EDITOR** of the *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

**FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements, etc.), *Articulate Westcent, London.*

**MEDICAL SECRETARY**, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Jacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumshugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

## QUERIES AND ANSWERS.

### CHRONIC ULCERS OF MUCOUS MEMBRANES.

"A. F." writes: A female patient, debilitated by frequent pregnancies, suffers from ulcers in the mouth and (she states) similar ulcers on the vulva labia. Extraction of teeth, the substitution of artificial teeth, tonics, and mouth-washes of potassium permanganate have failed to cure the patient. "A. F." thinks the condition must be systemic, and would be glad to hear of some effective treatment.

### ASTHMA AND BRONCHITIS.

DR. WILLIAM CORRIE (London, E.C.) suggests that "P." would be well advised to give his patient the benefit of inhalation therapy. This treatment has been in practice at the big Continental spas for many years, and has given splendid results in my own and others' hands in this country in many stubborn cases of bronchial asthma. The treatment consists in giving daily inhalations by means of a special apparatus of suitable inhalants reduced to vapour, which does very well on an aqueous solution of menthol, followed or combined with ether, amyl, menthol, and phenol. Severely treated, and the attacks tend to duration, and finally cease altogether. The apparatus can be hired or bought in London.

## URINARY STAINS.

DR. WILLIAM CORBET (London, E.C.) writes: If Dr. A. H. Skinner of Hankow is a cystoscopist he will find that phenol red works quite well if the bladder is distended with a sterile solution of sodium bicarbonate, a drachm to the pint. The most satisfactory dye, however, is indigo carmine 0.4 per cent., 10 c.cm. being injected intravenously. This is obtainable in sterile ampoules.

## TREATMENT OF DYSCHIEZIA.

DR. R. MACDONALD LADELL (Birmingham) writes in reply to "H. M.": It seems possible that the case might be treated successfully by means of psychotherapy. The desire for local treatment may be a substitution, a gratification which analysis would make clear and remove. If psycho-analysis is not considered desirable, it is likely that hypnotic suggestion alone would relieve the symptoms.

## INCOME TAX.

## Replacement of Car.

"A. H. L. T." bought a 10/15 "F" car in 1922 for £575 and sold it in 1925 for £220, buying a similar saloon car for £378; the latter car was not a success and in 1926 he sold it for £325, buying a 14/40 "S" saloon for £805. To what allowances is he entitled?

\* As a professional expense of the year 1925 on the grounds of obsolescence, the out-of-pocket costs—namely, £378—£220=£158; also, as an expense of the year 1926, the cost of replacing the unsuccessful car with one of similar make and power—that is, £378—£325=£53—the balance of expense represents additional capital outlay. As against the income tax assessment for 1926-27 he should also claim the percentage "depreciation" allowance at 15 or 20 per cent. on (£805—£53=) £752. These observations assume that the cars were used for professional purposes only; to the extent that they were otherwise employed the allowances should be restricted.

## LETTERS, NOTES, ETC.

## DRUG ADDICTS.

DR. E. E. DUFFY (Maltby) writes: I agree with Dr. Winter (August 14th, p. 328). Forty-six years ago I was apprenticed to a chemist and during six years we had three customers who took tincture of opium. I have had forty years in the medical profession and have never seen a drug addict. To me it seems legislation gone mad—something like the prohibition laws in America: faddists and cranks passing vexatious laws because a few degenerates have tried to get a new sensation out of a useless life by taking drugs.

## DRY CUPPING IN AUTO-HAEMOTHERAPEUTICS.

WET and dry cupping have, from time immemorial, been popular methods of treatment, and their popularity is not limited to any one country or indeed to any one civilization, for in one form or another cupping is practised in lands as far apart as France and China, Russia and Arabia. One of the commonest spectacles when travelling in some parts of the Near East is a man with shaven poll sitting patiently in the open air with half a dozen cupping glasses adhering to his scalp. The curious thing is that it should have almost dropped out of practice in Great Britain. Virtues it must have or it would not have maintained its reputation. But how does it act? Putting aside wet cupping, which, after all, is merely blood-letting on a small scale, the action of dry cupping is not easy to define and explain. It is always assumed to exert a local decongestive action, hence the cups are

applied to the skin in much the same thing as withdrawing blood and re-injecting it, on which the mode of treatment known as auto-haemotherapy is based. Exactly what auto-haemotherapy does is still a matter of doubt, but whatever it can be proved to achieve that can fairly be claimed for dry cupping. A plausible scientific explanation of its action and effects might rehabilitate cupping in daily practice.

## TREATMENT OF TIC-DOULOUREUX.

DR. FLORENCE THEOBALDS (Buxton) writes: It is known that calcareous deposits are common in the brains of old people, and such a deposit, even if minute, might easily be the cause of neuralgia, by direct pressure or by diminishing the blood supply. A year ago a woman, aged about 70, and with some signs of mental deterioration, had a typical attack of tic-douloureux. It was most distressing to see her. As her general condition suggested arterial degeneration, I prescribed dilute phosphoric acid, the juice of a lemon daily, and warm applications to the face. She had slow but steady relief. Each time the medicine has been stopped for a week or two she has relapsed, and it may have to be continued indefinitely. But it has been most successful so far, and she has responded well in other ways to the treatment. Whether the result in these cases is due to an increased calcium excretion I do not know, but the calcareous degeneration of the cerebral arteries seen *post mortem* in cases of senile dementia suggests that early treatment on these lines should be helpful and preventive.

## EFFECT OF LIGHT ON THE VITAMIN A CONTENT OF

## COD-LIVER OIL.

As the result of experiments in which cod-liver oil stored in air-tight bottles made of "Philadelphia oval" flint glass were exposed to diffused light, and in other cases to direct sunlight passing through windows, A. D. Holmes and Madeleine G. Pigott report in the *Boston Medical and Surgical Journal* for August 5th that there is evidence that the portion of the sun's spectrum which destroys the vitamin A content of cod-liver oil is not cut out by the type of glass employed in the manufacture of windows and flint bottles. Young albino rats, with vitamin A malnutrition, were used in the investigations were controlled. During the storage and distribution contained in amber bottles which are light-proof, or the bottles kept in cartons or paper wrappers.

## POTASSIUM CHLORATE IN CANCEROUS ULCERATION.

DR. VALLABHDAS N. MEHTA (Virangam, Bombay Presidency) writes: With reference to Dr. T. M. Allison's note (*BRITISH MEDICAL JOURNAL*, February 6th, p. 268) regarding the use of potassium chlorate internally in cancerous ulcerations, I have had the occasion to try it in a case of cancer of the tongue where there was extensive ulceration in the floor of the mouth, with severe pain and foul smell from the mouth. The patient, a female aged about 60, had suffered from this for about eight months, and the disease having reached an inoperable stage something that could relieve the intense suffering was greatly desired by the patient. Potassium chlorate, 10 grains in sweetened milk three times a day, and lead acetate, half a grain three times a day, greatly relieved the patient's suffering, and now she has practically no pain and no foul smell, and she can take the liquid and semi-solid food with great ease. In this disease, when it has reached an incurable stage, this treatment acts like magic, and is a great boon to patients suffering from such cancerous ulcerations. It is well worth a trial, as there is no other known treatment as yet which can do any good in advanced cases.

## NITROUS OXIDE ANAESTHESIA: STATUS LYMPHATICUS.

DR. O. LANGTON HEWER (London, N.W.) writes with reference to the note by Dr. Healey published on August 21st (p. 343): Babies are so intolerant of oxygen deficiency that it is a matter of considerable difficulty to anaesthetize them satisfactorily with nitrous oxide and oxygen. If we substitute air for oxygen, the difficult task becomes an impossible one. Might I suggest that the "status epilepticus" was in reality asphyxial excitation? With regard to Dr. Healey's remark that "anaesthetics in very young children are best avoided, if possible," I am in entire agreement if, by "anaesthetics," he refers to pure nitrous oxide.

## LONG UMBILICAL CORD.

DR. N. MOXON (Gainsborough) recently attended a woman, aged 40, in her fifth confinement, which was normal. The umbilical cord measured 53½ in. This is undoubtedly an unusual length, but whether a "record," as Dr. Moxon supposes, we cannot say.

## HOLIDAYS FOR FACTORY GIRLS.

WE have received the following letter signed on behalf of the Factory Girls' Country Holiday Fund by the Countess of Sandwich, the Bishop of Kensington, Sir Thomas Barlow, Dr. Mary Scharlieb, Miss Lilian Braithwaite, Dr. Frank Lloyd, and the Rev. Dr. R. F. Norton:

"We venture to ask you to allow us to make an urgent appeal for the Factory Girls' Country Holiday Fund. Our funds are low, and we fear that many who are hoping to go away during the next few weeks will be disappointed of their little holiday this summer unless we have a generous response to this appeal. Several of those who are hoping to go have never slept out of London before. The need for a brief rest and change is possibly greater this year than it has been for some time. Trade depression has resulted in many girls becoming the main support of their families. The health of the community in the crowded and airless districts of London has deteriorated considerably, and this is specially apparent in the women and girls. Nor has it been possible, although many of them have been saving up since the early spring, for them to contribute as much as usual this year towards their holiday. Good food and fresh air for a week or two work a marvellous change, and will make it possible for many to continue their work during the coming winter, and the short holiday gives fresh hope and courage. Subscriptions and donations will be thankfully received and acknowledged by the chairman, Mr. J. F. Green, or by Miss Canney, 75, Lamb's Conduit Street, W.C.1."

## ERRATUM.

IN the note on the treatment of tuberculosis in Lancashire on page 357 of the *JOURNAL* for August 21st, it should have been stated that twenty-four, and not fourteen, dispensaries are now in operation.

## VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 32, 33, 37, 38, and 39 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 34 and 35.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 140.

THE  
**British Medical Journal.**

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

LONDON: SATURDAY, SEPTEMBER 4TH, 1926.

EDUCATIONAL NUMBER. SESSION 1926-27.

THE PLACE OF ANATOMY IN MEDICINE.

BY

SIR ARTHUR KEITH, M.D., LL.D., D.Sc., F.R.S., F.R.C.S.,

CONSERVATOR OF THE MUSEUM, AND HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE life of a medical student, especially in its earlier years, is full of novel experiences and strange adventures. There is, for example, the October morning when he shyly pushes open the dissecting room door and, putting on an outward air of bravado to cover his inward trepidation, advances in search of the subject which is to afford him his first practical experience of human anatomy. As he discovers the object of his search we see him don immaculate apron and sleeves, undo the lid of a brand new case of knives, and seating himself by the subject, open his dissecting manual at the section devoted to the arm, impatient to commence operations. As he makes these preparations a sense of deep satisfaction takes possession of him, for he feels that at last he is to begin the real study of his profession. He had listened, but with only a half-hearted acquiescence, when his lecturers on chemistry, physics, and biology had claimed that theirs were the basal subjects of scientific medicine. But now all doubts had vanished; the stark subject which lies stretched on the table beside him measures the limits of his life's work; it is the field of all medical and surgical endeavour. No wonder, then, that the young student, as he makes his first incision and meets with those mysteries spoken of as superficial and deep fascias, feels that at last he has entered his profession. It was thus, in October days long gone by, that young medical students named William Harvey, Thomas Sydenham, John Hunter, Edward Jenner, Charles Bell, Marshall Hall, James Paget, and Joseph Lister entered the profession of medicine. Their first incision was also their blood-baptism to the profession of medicine. And so it will be in the future. Scalpel and forceps can never become antiquated, for as long as medicine endures, its practitioners must learn, by their use, the structure and working of the machine they would mend.

It is difficult for us who have grown grey in the service of medicine to recapture the enthusiasm, resolution, and outlook with which we first entered the dissecting room. The task ahead seemed so simple; the kingdom we had to conquer, the human body, had but a few parts—a head and neck, thorax, abdomen and pelvis, upper and lower extremities, and some special organs of sense. Its bones and muscles had been duly numbered and named; the shape and surfaces of its organs fully described; all its vessels and nerves had been charted. With

the optimism of youth we felt certain that before another October came round we should be masters of anatomy; by that time we hoped to have built up in our minds a picture or lay figure of the human body. This lay figure, reared in the dissecting room, we proposed to carry with us to the physiological theatre and laboratory, and there, as it were, have its machinery set in motion. It was to be for us what Maconochie became for Sir James Barrie—an *alter ego* which was to keep us company every day and everywhere. This anatomical Maconochie was, in due season, to go with us to the pathological department, and there his inward parts were to suffer all the diseases to which human flesh is liable; when the time came all the remedies of the pharmacopoeia should be tested on him and all his systems marked with therapeutic tags. He was to accompany us to the wards—if we ever got so far—there to serve as a lay figure on which we should graft experience gleaned from surgical and medical cases. Nay, in the distant future, when we had become practitioners, we conceived this lay figure, first built up by scalpel and forceps in the dissecting room, as the companion of our rounds—an epitomized embodiment of our medical knowledge—a representation of our whole stock-in-trade.

Why is it that in so many of us the zeal and enthusiasm with which we entered the dissecting room fade so soon and the anatomical "Maconochie" of our dreams is dead before the morning dawns? The art of dissection is laborious; the accounts given in textbooks are accurate, detailed, and prolix, but as dead as the parts described. Very soon, unless a teacher is at hand, the youthful student of anatomy becomes submerged in a chaos of fact. Some of the best minds which enter the profession of medicine turn from anatomy with contempt; for them it is but a catalogue of names. Besides, the student who would realize his early ideal and the teacher who would willingly help him, have to keep an eye on examination papers. In every question the candidate is desired to "describe" or "enumerate" or "give an account of" shapes, relationships, and attachments of certain structures. All references to the purposes these structures serve in the living body are excluded. The student, in such circumstances, abandons his earlier and truer ideal and accepts the conditions which tradition has made for him.

British teachers of human anatomy have realized more fully than those of any other country what is

wrong with their subject. Their subject has been killed by tradition, and if it is to take its place as the fundamental subject of medicine, they have to make it alive again. They are now revivifying it in many ways—by using living models as the subjects of their demonstrations and lectures, and by applying the discovery of Röntgen to the study of the living body. They desire that their students should carry from the dissecting room, not a memory of dead subjects, but of live men and women. No matter how high the ideals of the professor may be or how actively the demonstrator may supervise dissections, if this aim is to be attained—if the dead subject is to be made alive—each student has to do it for himself or herself. No one can perform this miracle for them. It is an easy matter to reflect skin, separate parts, and give a neat and clean demonstration of structures; to memorize descriptions is, at most, only a mechanical art, but to build up a living picture of each part as it is dissected, to ask and answer the questions What is the use of this structure? Why is it shaped so? entails real mental labour. Without this travail of the mind the labours of the dissector are thrown away and his time is largely wasted. It is this latter aspect of his work in the dissecting room which the modern student of anatomy fails to appreciate, and towards which his best books give him so little guidance. He clings to the hope that there is some easier way—some short cut—some system of mnemonics which will resolve his difficulties and assist him to satisfy the demands of his examiners. Sooner or later he will discover that in anatomy, as in all other branches of knowledge, there is for him but one royal road to learning—a diligent and intelligent application of all his mental powers.

It does not seem natural that the study of function should be separated from structure in the dissecting room, and it may happen that some student who reads this article will care to find out how anatomy became divorced from physiology. If he turns to the writings of John Hunter, which cover the latter half of the eighteenth century, he will find that anatomy, physiology, and surgery were taught by one man. John Hunter was a splendid anatomist, but when he dissected, his aim was to find out, not what an organ looked like, but what it did. He studied anatomy and physiology to get help in diagnosing and treating his patients. He studied dead things to understand the living, and observed living things to understand the dead. Then if the inquirer wishes to know how anatomy and physiology were taught early in the nineteenth century he should consult a textbook which was bought and read by medical students one hundred years ago. On its title-page this textbook is described as: *The Anatomy and Physiology of the Human Body*, by John and Charles Bell (sixth edition, in three volumes, 1826). These two brilliant brothers, like Hunter, taught anatomy and physiology and practised surgery. In their great textbook anatomy and physiology are blended to their mutual advantage. When the textbooks which were used by students of the following decade—the “thirties” of last century—are consulted it will be seen that a “judicial separation” by mutual agreement had been effected between anatomy and physiology. Not a teacher of the time, so far as one can find, entered any form of protest. Indeed, we have only to turn to a book which every student of medicine should read—*Memoirs and Letters of Sir James Paget*—to see that the change received an enthusiastic welcome. The passage which I quote relates to 1842, when Paget was 28 years of age, and

just beginning to get a foot on the first rung of the professional ladder:

“The time had come, in fact it had long ago come, when it was necessary to separate the teaching of physiology from that of anatomy. The separation had been made some years before at University College, and at the Aldersgate School, the rival neighbours of St. Bartholomew's, and in some other schools. It was now resolved to make it at ours; and my election to the physiological lectureship was sure. The plan was to have a lectureship on descriptive anatomy and another equal in rank and pay on general anatomy and physiology.”

In this way anatomy became divided into two branches—descriptive anatomy and general anatomy—physiology being appended to the latter. Very soon descriptive anatomists were named *anatomists* without any qualifying adjective, and general anatomists became known as *physiologists*. No doubt the separation of anatomy into two branches had become inevitable, but the student of to-day may wonder why cleavage took the line it did. He may wonder still more how it was that the anatomists of that time were content to hold the husk of the human body when other anatomists ran away with the kernel and called it physiology.

A search for an explanation will carry the inquirer into one of the most interesting episodes in the history of medicine. A reference to the writings of Dr. Robert Knox—a brilliant if somewhat unbalanced exponent of the anatomy of his time—throws much light on the matter. Knox was never tired of extolling the marvels of the new science invented in the schools of France—the “science of descriptive anatomy.” The anatomist's sole business, he held, was to give an accurate description of structure. There was also a science of form—“morphology”—but that, he held, had nothing to do with so mean an aspect of matter as function. Probably British anatomists would not have been content to remain mere “describers” had not Sir Richard Owen, during the “forties” of last century, leavened their subject by infusing into it his archetypal speculations. Owen's speculations were dying when, in 1859, Darwin led anatomists away on a new and very interesting chase—the search for the origin of man's body. Then, later in the nineteenth century, came the study of the human embryo, and the light that it threw on man's evolution. More and more the anatomist became the historian of the human body and concerned himself less and less with the action of its parts.

Without doubt anatomy as a subject has prospered and attained enormous proportions since the disruption effected almost a century ago. Its sister subject, physiology, has thriven out of knowledge. But the student of to-day, when he becomes the medical man of to-morrow, and has to relieve the ever-growing congestion in medical education, will doubt if anatomy and physiology have developed along the lines which are most profitable for medicine. For if he surveys the real additions which have been made to human anatomy in recent years he will see that they have been made, not by anatomists, but by physiologists. Gaskell, Langley, Ferrier, Sharpey-Schafer, Sherrington, and Head have been the best British anatomists of my time. Indirectly Joseph Lister has done more than all of them for the progress of practical anatomy, for he it was who gave the surgeon access to all parts of the body, and with every departure in surgery there opens up a new field in practical anatomy.

A renaissance is on foot in human anatomy. For

the good of medicine and the right progress of their own subject teachers of anatomy are no longer content to confine their efforts to mere description. They feel that the man who describes the anatomy of the brain and central nervous system must also, if labour is to be saved and time economized, deal with the mode in which its several parts perform their functions. Who could describe the human heart intelligently unless he explains its uses as a pump? Any account of the lungs, thorax, and respiratory passages is useless if the mechanism of the act of breathing is omitted. Sooner or later—and the sooner the better if the student is to be served—a new dividing line has to be drawn between the departments of anatomy and physiology, and that dividing line should not separate structure from function.

I seem to have struck a note of discontent with the present state of anatomy. An impression of this kind is not the one which I wish to convey to young men and women who are now beginning the study of the human body. A knowledge of how this body is made and how it works must provide the basis for all the more practical subjects of medicine. The beginner has to face the fact that to attain such a knowledge requires regular and unremitting application. Application, however, is not enough to attain success; toil soon degenerates into sheer drudgery unless interest is stimulated and maintained. How is this interest to be maintained?

There are many ways. One of the best is to acquire the habit of reading medical journals; never a week passes but there are reported clinical and other cases which have a bearing on anatomy, and in this way students come in touch with the latest applications of their subject to medicine. Besides, this habit of keeping in touch with medical literature is one worth acquiring for its own sake; it will stand students in good stead when they have become busy practitioners or have joined the ranks of consultants

or of specialists. Another way of maintaining interest in anatomy is to make occasional visits to the operating theatre, to out-patients, or to the x-ray department. A visit to the *post-mortem* room will often give a practical bearing to what the student may have observed in the dissecting room. A glimpse now and then at the pages of *Proceedings* and other publications issued by anatomists and physiologists will place him in touch with subjects which are interesting his teachers and reveal the lines along which new fields of research are being opened up. At least a pastime of this kind will remove from the student's mind a delusion widely held by the public at large—that all worth knowing about the human body has been discovered long ago.

I would not take away a single moment of the leisure which the student proposes to give to general literature—nor to amusement or sport—but there are many books on medical biography which will well repay study and help to maintain interest in anatomy and physiology. Especially would I commend the lives of Harvey, Hunter, and Marshall Hall. Every student should get to know John Hilton's book on *Pain and Pleasure*, not only for what he has to say, but also for the way he says it. Then there are a number of excellent modern books which deal with the evolution of the human body, and explain the history of its many curious structures. For my part I still find great profit in reading Archdeacon Paley's *Natural Theology* and Sir Charles Bell's *Bridgewater treatise*. The explanations they give may have become antiquated, but the facts and contrivances they describe are still before our eyes, and the manner in which these authors place their facts before the reader has a charm and clarity which are still unexcelled. By such diversions the student will relieve the monotony of the more routine studies required of him by teachers and examiners, and qualify himself, not only for the work of life, but to take a wide and permanent interest in the welfare of his profession.

## The Profession of Medicine.

### INTRODUCTORY.

OUR present issue, in accordance with long-standing custom, is the annual Educational Number of the *BRITISH MEDICAL JOURNAL*, and the remarks that follow, on the profession of medicine, are addressed more particularly to intending students and their parents. In an article of this kind it would be out of place to discuss medical politics, but the occasion may be taken again, as in past years, to touch on a few current matters affecting professional study and practice. Our object in doing so is to put certain considerations before those who think of devoting themselves to medicine, and thus help them to judge of their fitness for the profession and of the prospects it holds out. It seems appropriate, therefore, to quote here from the opening words of a valuable paper on "common sense" by Dr. L. G. J. Mackey, which appeared in our columns early this year.<sup>1</sup>

"From the very outset of the student's life common sense is necessary; in fact it is needed before a parent can come to a decision as to the suitability of his son or daughter for a medical career. It would be an act of common sense for a boy or girl who wishes to become a doctor to ascertain the conditions of medical practice, its labours and rewards, its openings and its opportunities; yet in far too many instances the student toils through years of arduous work to find himself at last a member of a profession for which

he has neither the taste, temperament, nor physique. Common sense will tell the medical student whether he has embarked on the right career; when to work and when to play; how to choose his teachers and his books; how best to gain the necessary knowledge; how to distinguish essentials from trivialities; it will prevent him being led away by new and unproven things from simple, sound, established principles and facts; and will finally be of great help to him in passing his qualifying examinations."

### THE GROUNDWORK OF MEDICAL STUDY.

The Educational Number is largely a guide to the steps that must be taken and the studies that must be pursued in order to become a legally qualified practitioner. With the passage of years the form and contents of this issue have undergone changes, but its primary object remains unaltered. It contains also certain sections intended for younger members of the profession who may be in doubt as to the path in medicine they should choose as a career, and a section on the existing opportunities for post-graduate medical study in Great Britain. The particulars given are founded for the most part on official information, and are arranged along the customary lines. Apart from these and other special articles, the prospective student will find in subsequent pages an account of the course of training required of him, the places where it can be obtained, and the universities and other licensing bodies which test the knowledge gained and issue degrees or

<sup>1</sup> *BRITISH MEDICAL JOURNAL*, January 30th, 1926, p. 211.

diplomas entitling successful candidates to become registered medical practitioners.

Here we may emphasize once more the need, which increases with the advance of scientific medicine, for a thorough grounding in the fundamentals of science. One of the best pieces of advice that can be given a student, especially in the early years of the curriculum, is not to work at any branch of study as though his only object were to pass the examination. He should work to obtain knowledge for its own sake. The student of good intelligence who makes it his aim to grasp the principles of each of the basic sciences need have little dread of examiners. In mastering the principles he will find that the larger details take on new meanings and a new interest, and are thereby fixed in his memory. The proverb about the pence and the pounds is wholly inapplicable here: in medical study one must take care of the principles and the details will take care of themselves. Moreover, the Institutes of Medicine—as the preliminary sciences used to be called—provide a drilling in exact methods, in precise manipulations, and in vigorous reasoning; which will bear immediate fruit in the later clinical part of the curriculum, and prove of lasting benefit throughout professional life.

The purpose of medical education is to build up on scientific principles a solid structure of practical knowledge. Students who keep this in mind will look upon "cram work" as a weakness in the foundations and therefore as a hidden danger to the superstructure. They will gain an understanding of the true meaning and purpose of their anatomical and physiological studies if they will read and re-read the article on "The Place of Anatomy in Medicine" which Sir ARTHUR KEITH has written at our request as an introduction to this Educational Number. No pen is better able to inspire the true "student habit," or to indicate in telling phrase the connexion between the basic sciences and the art of medicine.

#### PORTALS OF THE PROFESSION.

Those who are not familiar with the conditions of medical teaching and examination in these islands, and with the history of our professional institutions, are apt to be confused at first sight by the number and variety of portals through which admission may be obtained to the *Medical Register*.<sup>1</sup> The table of contents to this Educational Number shows that there are no fewer than twenty-seven bodies—eighteen universities and nine corporations—which either separately or jointly issue registrable qualifications, and that the choice of teaching institutions is even wider. Nevertheless, although there is no single State examination in medicine in this country, the medical courses of the various universities and schools in Great Britain and Ireland run on parallel lines, and the obligatory curriculum is much the same for all students. Within these broad lines there are, however, many differences between the requirements of the individual teaching and examining bodies. The choice should therefore be made early, so that a definite plan may be followed throughout the years of study. To prevent a false step at the outset the student and his advisers should try to obtain a clear idea of the object to be aimed at, of the relative advantages of taking one or other of the degrees or diplomas open to him, and of the comparative difficulties they present.

All who wish to enter the medical profession must comply with certain conditions. These are regulated by the General Medical Council, which is a statutory body established under the Medical Acts; a statement of its requirements is given at page 417. Many changes have lately been made in the medical and pre-medical curriculum,

<sup>1</sup> The *Medical Register* is the official statutory list of qualified medical practitioners kept by the General Medical Council.

and this section, as well as the article on Professional Study and Examination, should be studied with care. Every medical student, after passing examinations in the subjects of general education and in the preliminary sciences, must take a course of training at a recognized medical school, covering at least a period of five years, but usually extended to six years or more. The examination of candidates as to their fitness to practise medicine, surgery, and obstetrics is left to the licensing bodies, which are of two kinds—the universities, and certain medical corporations in England, Scotland, and Ireland. An account of the requirements of the several licensing bodies will be found elsewhere under separate headings. One of the functions of the General Medical Council is to make sure that the tests at each stage do not fall below a certain standard, and that the students examined have undergone prescribed courses of instruction at recognized institutions. Successful candidates at such examinations eventually receive from the body holding them either degrees, in the case of a university, or diplomas or licences, in the case of a corporation; these qualifications entitle them to claim insertion of their names in the *Medical Register* kept by the General Medical Council. Holders of diplomas and licences once made up the great majority of all medical men, especially in England and Wales. But universities have greatly multiplied, and so many practitioners are now graduates that in almost all cases the wisest plan for a student at the threshold of his career is to aim at a medical degree, though it may be desirable to take also a diploma or licence.

#### COST OF MEDICAL EDUCATION.

It is ordinary prudence to count the cost before embarking upon a career, and some guidance on this matter will be expected. The first thing to be said is that the cost of a medical training varies within wide limits. Besides differences in the charges made by medical schools for instruction there are differences in examination fees as well as in the fees for certificates of qualification, and those who aspire to the higher degrees and diplomas must expect to pay more for the additional courses and tests and certificates. Again, not all students, however industrious, pass examinations with equal facility, and every setback due to failure in the examination room or to illness means added expense. School and examination fees, together with the cost of board, lodging, clothes, and recreation, form the largest items of expenditure, and to these must be added the money spent on books, microscope, osteology set, instruments, and so forth. Since professional education must in any case continue for five years at least (a period exceeded by the vast majority), and since the cost of living in different parts of the country varies much, while personal expenditure varies still more, it can only be said in a general way that anyone who thinks of entering the profession should reckon on an outlay—first and last—of at least £1,500. On the other hand, the number of scholarships and money prizes now offered is larger than in the past; in the Scottish universities bursaries are numerous, and the Carnegie Trust (whose regulations are summarized at page 428) gives financial assistance to many Scottish students. The main thing to bear in mind is that, as compared with other professions, the period of training in medicine is long, and for most students costly. There is also to be remembered the time of waiting after qualification, when income is apt to lag behind expenditure.

#### THE NUMBERS OF MEDICAL STUDENTS.

Medical students are not commonly the sons or daughters of wealthy parents; very often their education puts a heavy strain on a slender family purse. Hence, before setting out upon this long and exacting course of study, it is usual

to weigh, not only the cost, but also the prospects. An overcrowded curriculum is hard to face if all that can be discerned at the end of it is an overcrowded profession. Without forgetting the adage that "there is always room at the top" the youth and the girl of to-day, when reckoning up their chances in any calling, will seek some information about the probable numbers of their competitors for the work that is waiting to be done.

One effect of the war and of after-war circumstances was a great increase in the number of medical students, both men and women, but especially women. The climax was reached during the twelve months after the armistice. The following brief survey of the position should be read in conjunction with the note on page 415 on the numbers of registered practitioners.

In the thirteen years before the war the annual entry of medical students in Great Britain and Ireland averaged about 1,400; during the war period, although many students left to serve with the forces, the whole number actually studying in the schools grew steadily larger. In 1914 the entries rose to 1,600, and in 1915 to 1,918; in 1916 they were 1,875; in 1917 they rose again to 2,150, and in 1918 to 2,253; and in the following year, when demobilization was in active progress, as many as 3,420 new students were registered. After 1919 the number of entries rapidly fell. In 1920 they were 2,531, in 1921 they were 1,808, and in 1922 they were 1,833.

In 1923 the number of newly registered students dropped to 545, and the reasons for the fall have been discussed by Sir Donald MacAlister in his presidential addresses to the General Medical Council. Speaking in 1924, he suggested that the sudden decline was more apparent than real, and attributed it to the recent introduction of a pre-registration test in elementary physics and chemistry. This explanation has been borne out by the figures for the two following years, for in 1924 the registrations of students were nearly doubled, reaching 1,043 by the end of the year, and in 1925 they numbered 1,570.

The recent decline in the numbers of new students is to be welcomed for several reasons. In the first place it has eased the very heavy burden thrown upon the teaching resources of the medical schools. From another point of view it is an advantage because excessive entries of students lead to overstocking of the profession. In the past four years the numbers of new practitioners registered have greatly exceeded the usual pre-war figure of eleven hundred or thereabouts. The registrations in 1922 numbered 1,983, they rose to 2,482 in 1923, they rose still further to 2,796 in 1924, and last year they were 2,570. The large additions to the profession in recent years brought the total number of names in the *Medical Register* up to 51,738 at the end of 1925. This is nearly ten thousand more than the corresponding figure for 1913, and the ratio of qualified medical practitioners to population is now much greater than at any previous time. It is no doubt true that, with the progress of medical science and its growing appreciation by the public, the scope of medical practice has widened and new openings for professional work have appeared; but there must be limits to the demand for qualified medical practitioners, and the supply of new practitioners ought not to outstrip the medical needs of the community. The new regulations, which came into force at the beginning of 1923, should do something to keep the entries of students—and, as a consequence, the numbers of the profession—within manageable bounds.

#### CHOICE OF A CAREER IN MEDICINE.

The student, having passed all his tests and placed his name on the *Medical Register*, becomes a member of the profession and assumes the privileges and responsibilities that go with legal qualification. But the final examina-

tion, though a great event, is only the opening of a door into a wider field of training and experience. Education must continue throughout his career: a good doctor remains always a student. As an introduction to practice of whatever kind nothing is so useful as a year or more spent in junior hospital appointments; and all who can afford the time should look upon the holding of such posts as a most valuable investment. Next comes the choice of a career in the larger world of medicine. Many paths are now open—for example, general practice, Government service at home or abroad, and special work in public health and mental disorder, in scientific research, or in one of the many modern subdivisions of medicine and surgery. Most of these careers are discussed in some detail in the later sections of this number, but a few words may be said here about general practice and the work of a consultant or specialist.

A good deal of information on these and other cognate matters will be found in the *Handbook for Recently Qualified Medical Practitioners*, of which a revised and enlarged edition has lately been published by the British Medical Association.<sup>1</sup> The new edition should be found of assistance by all members of the profession, although it is issued primarily to meet the needs of newly qualified members by giving useful information and advice on matters which are often a source of doubt or difficulty to those planning their future career. The *Handbook* includes sections on the main openings for members of the profession; on some practical aspects of medical work, especially the legal and ethical aspects; on registration and the privileges of practitioners; on medical work under the National Health Insurance Acts; on post-graduation study and special diplomas; on specialization; on the fellowships, scholarships, studentships, prizes, and research grants open to students and practitioners; and on individual medical defence. The new section on practical aspects of medical work, specially prepared for this edition, will be found of much value; it embodies a great deal of advice on professional conduct and the relations between members of the profession. The section on specialization and consulting practice is also new, and will repay study.

#### GENERAL PRACTICE.

In the nature of things, general practice has always been, and is likely to remain for some time, the goal of the great majority of medical students. The life is onerous and exacting and the remuneration too often inadequate; but there are compensations, and for one reason or another many of the very best students—men of high intellectual capacity—become general practitioners. The work of these men is of the utmost value to the public and the profession, because it sets a standard for the branch of medicine in which the great bulk of students sooner or later become absorbed.

This career is usually entered upon in one of three ways. The newcomer may take a house and wait for patients to seek his services; he may purchase the goodwill of a practice rendered vacant by retirement or death; or—perhaps best of all—he may become a partner in an established practice. A well managed multiple partnership has obvious advantages over single-handed practice; for instance, it allows each partner leisure for recreation and for keeping up with the progress of medical art and science. Success in the work of a private practitioner demands a great deal of knowledge other than that gained at the medical schools, and consequently a man is more likely to be accepted as a partner, or to do well on his own account, if he has already some experience of family practice as an assistant or deputy. A considerable

<sup>1</sup> *Handbook for Recently Qualified Medical Practitioners*, 1925. British Medical Association, Tavistock Square, W.C.1. (5s. 6d. net; post free 6s. 6d.)

proportion of general practitioners, therefore, begin their work as assistants, and of these there are few who afterwards find reason to regret the time spent in learning the ropes under the eye of an experienced senior. As the conditions of general practice vary much in different parts of the country and even in the same district, it is usually best to undergo this "post-graduate apprenticeship" in circumstances and surroundings resembling those to be encountered later.

An all-round knowledge of practical medicine, surgery, and obstetrics should, if possible, be supplemented by skill in some particular branch of practice. Moreover (as already indicated) the value to a general practitioner of having held one or more resident hospital posts is incalculable. Those who have been thus trained acquire a confidence and reliance and experience which they cannot easily obtain elsewhere. With this opinion Dr. Mackey, whom we have quoted at the beginning of this article, is in agreement, though he makes one proviso. Speaking of the need for common sense in deciding what branch of medicine a newly qualified man should take up he says:

"If he has decided to go into general practice he will take some appointment where he can make his early mistakes without disaster to the patient or himself, and at the same time gain the very necessary practical experience which can only come from daily contact with the sick. A resident post in a good hospital is invaluable at this stage, provided a man has the common sense to realize that the proportion of rare and serious cases is far higher than he is ever likely to encounter in private practice, that the surgeons and physicians are not as a rule intimately acquainted with the conditions of general practice, and that a successful autopsy, however educative to oneself, cuts very little ice with the general public."

Before leaving this subject it ought perhaps to be added that the strain of busy general practice is so heavy and often so continuous that only those of sound physique can hope to last the course. Night work, irregular meals, and long winter drives during epidemics will tax the strength of a strong man. It is one of the drawbacks of a single-handed practitioner's life that, unless he has made some arrangement with a neighbouring colleague, he must be ready to answer a call at whatever hour it comes and however unfit for a fresh task he may happen to feel.

#### CONSULTANTS AND SPECIALISTS.

Specialization has gone so far in recent times that only a few observations of the most general kind can be made here. Exactly where specialism begins and consulting practice ends would be hard to define; but the latter term may be said to cover in ordinary usage the work of the general medical consultant (once spoken of in this country as a "pure physician," and known nowadays in America as an "internist") and that of the general surgical consultant or operating surgeon. Most general consultants, whether medical or surgical, are specialists in some branch of their work, and most, if not all, specialists are consultants in the sense that their work largely comes to them through the recommendation of other practitioners with whom they act (or should act) in a consultative capacity. In any case, whoever holds himself out as one or the other or both must be assumed to have special knowledge and skill. Intensive study and practice after qualification are therefore obligatory, and the experience of hospital appointments invaluable. Nevertheless, for those who aim at becoming consultants or specialists, success will depend in the long run, not only upon mental gifts, special experience, and capacity for hard work, but (as is true of practitioners of all branches) on the possession of those qualities which inspire confidence both in patients and in colleagues. In the practice of medicine, personal tact and character are as important as scientific equipment. Moreover, since the consultant or the specialist can scarcely hope at first to pay his way by consulting work or by the

exercise of his specialty, he must either have the means to support himself for an uncertain period or be prepared by teaching or in other ways to defray expenses. A successful physician, surgeon, or specialist is made, not born, and the process of making himself is not remunerative. If while preparing himself for his life work he can manage to undertake some piece of research bearing upon his clinical studies, this is strongly to be recommended.

The question of additional degrees and diplomas is of special moment to those whose ideas turn in this direction, if only because these are important factors in securing election to the visiting staff of a hospital. Beyond the qualifications, such as Bachelor or Licentiate, which admit to the *Medical Register*, most of the licensing bodies bestow higher titles, such as Doctor, Master, or Fellow, after further tests. For the career of a consulting physician the M.D. degree of a university is usually necessary, and also the Membership of one of the three Royal Colleges of Physicians, according to the part of the British Isles in which practice is contemplated. In the same way, the Fellowship of one of the three Royal Colleges of Surgeons should be sought by those proposing to devote themselves to surgery. There are also diplomas in a growing number of special branches of work, such as public health, tropical medicine, ophthalmology, radiology, and psychological medicine, which are superfluous for most practitioners, but useful or even indispensable for the medical man or woman who wishes to specialize in one or other of these subjects. Information about the several diplomas will be found elsewhere in this issue.

For all consultants and specialists ample occasions for exchanging ideas and information with their fellow workers are most necessary. Such opportunities are provided by the meetings of the various medical societies, metropolitan and local; by the discussions in the scientific Sections of the British Medical Association's Annual Meetings; and by the medical journals, both general and special.

#### FINANCIAL AND SOCIAL CONSIDERATIONS.

It has never been easy to assess the attractions of medicine as a means of livelihood, and at the present moment this would perhaps be more difficult than ever. On the financial aspect of our profession two or three remarks only need be made, and those of the nature of truisms. Medicine is not to be regarded as a path to fortune, and anyone who enters it with the sole idea of making money has mistaken his calling. The competent practitioner can always make a living; but the main reward of the medical life is the knowledge of good work well done. Whatever the branch of medical work chosen, there are few doctors who become what a business man would consider even moderately rich by the practice of their profession.

But if medical practice, from the financial point of view, offers to the majority little more than a means of livelihood, in its social and intellectual aspects the prospect is far brighter. The culture which once belonged to the physician alone, entitling him to his place among members of the learned professions, has spread, and is spreading further, into all ranks of the practitioners of medicine. The great improvement in the education, general as well as technical, of the practitioner has added much to his influence with the public, and has been a large factor in raising his social status during the sixty-eight years that have passed since the General Medical Council was constituted under the Medical Act of 1858. A family doctor of the kind that is well styled "the backbone of the profession" occupies an excellent position among his neighbours, and is the friend and confidant as well as the medical adviser of many of his patients. Many such men go further and take a leading part in the public life of their district.

## PRIVATE PRACTICE: THE OUTLOOK.

The prospects held out by the various public medical services are indicated in later sections of this Educational Number. Here may be noted very briefly some circumstances of to-day that have a bearing on private practice. In the first place, it is now more and more recognized that one of the chief duties of the State is to concern itself intimately with the health of the people. Side by side with this, efforts are being made to bring professional training more into line with the growth and differentiation of medical science, and so to raise the level of medical practice; it was with that end in view that the student's curriculum was lately recast. Next, the fundamental importance of the work done by the general practitioner is better understood, and it is more fully acknowledged that an efficient medical service for the community must be based upon the skill and devotion of the family medical attendant, working in close touch with the aims and methods of preventive medicine. Just as the State now looks on its family doctors as its first line of attack upon disease and disability, so the private practitioners of to-day take a wider view of their duty towards the environment and the habits of their patients.

Changes are thus gradually coming over the practice of medicine. As Lord Dawson has said in a recent speech to medical students, the centre of gravity is drifting away from disease and towards health. The doctor of the future will come more and more to study early disturbances of function—the threshold of disease—and the maintenance of bodily and mental health.

While this is all to the good, it cannot be denied that increasing contact with public authorities brings with it new and often irksome demands, and the multiplication of official requirements and administrative checks has a tendency to cramp the doctor's independence of action. The national insurance system, now more than fourteen years old, has already had a profound influence upon the private practitioner and his work; so much so that it needs some little effort to recall clearly the conditions of industrial medical practice before the year 1913, both as affecting the medical profession and the very large section of the community which became insured under the Act of 1911. The Insurance Medical Service now comprises nearly 14,000 practitioners, some doing much work among insured persons, others little. If the freedom of family practice and the robust individualism of the private practitioner have been restricted by the Insurance Acts and Regulations, there is a general belief (borne out by the findings of the recent Royal Commission) that the panel system has provided a better service than existed under the old "club" arrangements, though it is by no means as complete or as effective as it might be made. "The reform that is most required in connexion with the insurance service is one which shall link up the insurance practitioner with the consultant physician and the consultant surgeon, and give the insured patient the benefit of the profession's specialized as well as of its general knowledge."<sup>1</sup> Whether the payment is adequate to the services required is open to doubt, but it is easier now for a doctor to make an assured income out of attendance on working-class patients. The full effect of the insurance scheme upon the medical profession as a whole, and upon the private practitioner as an individual, is as difficult to gauge as its effect upon the public health. Some of its most objectionable features have been removed through the efforts of the Insurance Acts Committee of the British Medical Association, which represents the interests of insurance practitioners in all negotiations with the Government. A factor that has contributed perhaps more than

anything else to the smooth working of the national insurance scheme is the patient's right to choose his own medical adviser—a right insisted upon from the beginning by the Association and maintained throughout.

## PROFESSIONAL ORGANIZATION.

The spirit of comradeship, which adds so much to the value and happiness of undergraduate medical study, is at least as great a boon to the qualified practitioner. This *esprit de corps*, arising out of common ideals and associations, should be preserved for its own sake. But there is a sound material reason, too, for all holding together.

In the times in which we live no doctor, whatever his position or the nature of his work, can safely stand aside from his fellows. Medical men and women must therefore band themselves together for their common protection. Experience shows that individuals and isolated bodies of practitioners are always handicapped when they attempt to defend their own interests unsupported by their fellows against organized bodies. This applies, whether the organized bodies are Government departments, local authorities, or bodies of workmen. While in ordinary circumstances the individual doctor is quite able to deal with the individual patient and the patient's friends, he cannot hope to engage successfully in single combat with outside organizations.

For these reasons the first step after registration should be to become an active member of the British Medical Association. Besides the advantage of having behind him the machinery and the influence of a world-wide professional body, a young practitioner will find in the meetings of his local Division, and in the Annual Meetings of the Association, held in large medical centres, many opportunities, both of keeping abreast with the progress of medicine, and of friendly intercourse with colleagues. One other thing that no new graduate should fail to do is to join one of the professional societies which for a small yearly sum undertake individual legal defence of their members.

The British Medical Association, whose membership is now more than 31,000, was founded in 1832 to promote the medical sciences and to maintain the honour and interests of the profession. It is the great general forum of the profession throughout the empire, and the one body which acts for the profession as a whole in times of stress. A brief note on the objects and constitution of the Association, and what it does for its members, will be found at page 467. The record of ninety-four years' work shows that professional organization, directed with wisdom and imagination, can combine service for its members with service for the public. Greater work remains to be done in each direction, and we look to the rising generation of doctors, not merely to consolidate the ground won, but to press forward.

## PROFESSIONAL STUDY AND EXAMINATION.

## A NOTE ON THE REVISED SCHEME.

In the article appearing at page 417, on the functions and requirements of the General Medical Council, there will be found an account of the resolutions and recommendations of the Council which have applied since the beginning of 1923. It will be convenient if we summarize here the leading features of the revised scheme of professional study and examination, and indicate the importance attached by the General Medical Council to the preventive aspects of medicine.

*The Revised Curriculum.*

The minimum age for registration as a medical student has been increased from 16 years to 17 years. Formally, the length of the medical curriculum is not added to; practically it is, by transferring to preliminary study

<sup>1</sup> R. G. Hogarth: Presidential Address on "The Medical Practitioner and the Public," delivered to the British Medical Association at Nottingham. *British Medical Journal*, July 24th, 1925.

and examination the subjects of elementary physics and chemistry in their purely scientific aspects. In the applications to the professional courses—as in biophysics, biochemistry, and pharmacological chemistry—appropriate instruction is to continue throughout the curriculum, and is to be tested by examination, so that the student shall no longer be able to put behind him as passed and done with the knowledge which he acquired as a preliminary. If he has had no facilities at a secondary school or otherwise for obtaining what is necessary for the preliminary examination in these subjects, then he can come for it to the university or college, but study there will not count for the medical curriculum. In biology comparatively few secondary schools are equipped for elementary tuition, but the Council has suggested an arrangement for utilizing the work of such schools as are qualified for the purpose. The examination will not be “pre-curriculum,” but the instruction may be so, and a licensing body can allow students who so desire to sit for the examination immediately after matriculation. Here again, however, the applications of biology to medicine, surgery, and midwifery will continue to receive attention throughout the courses.

Besides the resolutions of the General Medical Council in regard to professional education and examination printed elsewhere, a series of additional resolutions was adopted in 1922, as follows:

(a) That throughout the whole period of study the attention of the student should be directed by his teachers to the importance of the preventive aspects of Medicine;

(b) That each Licensing Body should make adequate arrangements for the effective correlation of the several subjects of study throughout its curriculum;

(c) That the teaching of Anatomy and Physiology should include as a regular part of the courses the demonstration on the living human body of structure and function;

(d) That the curriculum should be so arranged that a minimum period of three years shall in every case be available for study after the completion by the student of the Professional Examinations in Anatomy and Physiology held at the close of the second year;

(e) That the curriculum should be so framed as to afford sufficient opportunities for the study, during the last three years of the course, of Physics, Chemistry, Biology, Anatomy, and Physiology in their practical application to Medicine, Surgery, and Midwifery, and that the student's knowledge of these applications should be subject to test in the Final Examination;

(f) That before the student is admitted to his clinical appointments he should have received practical instruction in clinical methods and in the recognition and interpretation of physical signs;

(g) That instruction should be given, in the courses of Forensic Medicine and Public Health or otherwise, on the duties which devolve upon practitioners in their relation to the State, and on the generally recognized rules of medical ethics. Attention should be called to all Notices on these subjects issued by the General Medical Council.

The Council, it will be noted, attaches great importance to the reservation of sufficient time for the later subjects of study, free from all worries about passing the examinations of the earlier parts. To that end it recommends what is practically a block system. A minimum of three years should be available, not merely after the courses of anatomy and physiology have been taken, but after the examinations in these subjects have been passed.

#### Examination Reform.

Another notable feature is that in assessing marks in the several examinations account may be taken of “duly attested records of the work done by the candidate throughout his course of study” in the subject. This is an effort to meet the long felt difficulty that a man's mental agility, or the want of it, counts far too much in the examination room. The difficulty is real, but the remedy is not easy, and the Council has been wise in the cautious approach it makes towards a solution. Where, as in the examinations for the various conjoint diplomas, a student will only by chance come before his own teacher as an examiner, absolute impartiality in the attested records

will be necessary. On the other hand, at the universities, where the teacher is almost always one of the examiners, no personal like or dislike of a student must influence the report of the internal to the external examiner. The class records should, of course, be available, but the scheme will put a serious ethical obligation on all concerned, and the Council will doubtless watch its operation with keen and critical interest.

#### Training in Preventive Medicine.

The first of the resolutions quoted above should be borne in mind by every teacher throughout the whole curriculum, and not merely in the clinical subjects. All the earlier subjects—physics, chemistry, biology, physiology, anatomy, and, of course, pathology, bacteriology, and therapeutics also—afford opportunities from the very beginning for instilling into the mind of the student the necessity for his keeping constantly in view, in all the advice and treatment he may give throughout his professional life, the primary importance of promoting the general health of those who entrust themselves to his care, and of preventing trivial ailments from developing into definite disease. The era of that training began formally in 1923. Though no details are given in resolution (a), and though it may require some change of orientation by teachers who have hitherto given no special heed to the bearings of their subject on the maintenance of health and the prevention of disease, yet they will doubtless join heartily in what will indeed be an epoch-making advance in medical education in this country. Its reflex and reward will surely be found as time passes in a diminution of sickness and prolongation of life, in the raising of the present standards of physical health and national welfare.

## THE NUMBERS OF THE MEDICAL PROFESSION.

### A REVIEW OF FIFTY YEARS.

SINCE the year 1876 the General Medical Council has kept an analytical record of the number of names entered in, added to, or removed from the *Medical Register* in each twelve months. The *Medical Register* has been published annually since the Council was constituted under the first Medical Act of 1858; but before 1876 no such data as these were ascertained or preserved.

In order to gain a general view of the numerical strength of the medical profession during the past fifty years we have extracted from the tables and set down below in parallel columns the total number of names in the *Medical Register* on December 31st of each year, and the numbers added annually by registration between 1876 and 1925.

#### Numerical State of the “Medical Register.”

| Year. | Names added<br>in Year. | Total No.<br>on Dec. 31. | Year. | Names added<br>in Year. | Total No.<br>on Dec. 31. |
|-------|-------------------------|--------------------------|-------|-------------------------|--------------------------|
| 1876  | 1,009                   | 22,713                   | 1901  | 1,318                   | 36,912                   |
| 1877  | 940                     | 22,841                   | 1902  | 1,275                   | 37,232                   |
| 1878  | 996                     | 22,600                   | 1903  | 1,233                   | 37,878                   |
| 1879  | 996                     | 22,516                   | 1904  | 1,168                   | 38,492                   |
| 1880  | 1,123                   | 22,936                   | 1905  | 1,240                   | 39,060                   |
| 1881  | 1,053                   | 23,275                   | 1906  | 1,197                   | 39,529                   |
| 1882  | 1,171                   | 23,801                   | 1907  | 1,221                   | 39,827                   |
| 1883  | 1,304                   | 24,517                   | 1908  | 1,137                   | 40,257                   |
| 1884  | 1,388                   | 25,321                   | 1909  | 1,143                   | 39,818                   |
| 1885  | 1,377                   | 25,998                   | 1910  | 1,062                   | 40,483                   |
| 1886  | 1,431                   | 26,452                   | 1911  | 1,042                   | 40,913                   |
| 1887  | 1,531                   | 27,246                   | 1912  | 1,157                   | 41,439                   |
| 1888  | 1,184                   | 27,939                   | 1913  | 1,168                   | 41,940                   |
| 1889  | 1,305                   | 28,348                   | 1914  | 1,433                   | 42,378                   |
| 1890  | 1,266                   | 29,163                   | 1915  | 1,526                   | 43,225                   |
| 1891  | 1,345                   | 29,555                   | 1916  | 1,202                   | 43,461                   |
| 1892  | 1,513                   | 30,590                   | 1917  | 1,134                   | 43,819                   |
| 1893  | 1,579                   | 31,644                   | 1918  | 1,077                   | 43,926                   |
| 1894  | 1,426                   | 32,637                   | 1919  | 1,322                   | 44,510                   |
| 1895  | 1,446                   | 33,601                   | 1920  | 1,457                   | 44,761                   |
| 1896  | 1,385                   | 34,478                   | 1921  | 1,760                   | 45,408                   |
| 1897  | 1,230                   | 34,642                   | 1922  | 1,983                   | 46,476                   |
| 1898  | 1,210                   | 35,057                   | 1923  | 2,482                   | 48,140                   |
| 1899  | 1,351                   | 35,836                   | 1924  | 2,796                   | 50,035                   |
| 1900  | 1,345                   | 36,355                   | 1925  | 2,570                   | 51,738                   |

The following table indicates the varying proportion of registered medical practitioners to population during the period under review. It gives the population of the British Isles at each decennial census since 1881, and the number of names on the *Medical Register* in the same year;

also the corresponding totals for the year 1925, that for the general population being an estimate.

*Proportion of Practitioners to Population.*

| Year.      | Registered Practitioners. | Population, British Isles. |
|------------|---------------------------|----------------------------|
| 1881 ..... | 23,275 .....              | 35,241,482                 |
| 1891 ..... | 29,555 .....              | 38,104,975                 |
| 1901 ..... | 36,912 .....              | 41,976,827                 |
| 1911 ..... | 40,913 .....              | 45,370,530                 |
| 1921 ..... | 45,408 .....              | 47,263,196                 |
| 1925 ..... | 51,738 .....              | 48,225,000                 |

These figures show a general tendency (much more marked in recent years) towards an increase in the ratio of doctors to population. The number of registered practitioners at the end of 1921 was almost exactly double the number at the end of 1876, but the population of Great Britain and Ireland within that period only increased by about 50 per cent. During the year 1925 the new medical registrations numbered 2,570, and there was a net increase of 1,703 names. Owing to the large increases during the past five years, reflecting the excessive entries of students immediately after the war, there is now more than one name in the *Medical Register* to every thousand of population. In the United States of America, according to an estimate by the *Journal of the American Medical Association*, there is at the present time one medical practitioner to every 753 people. Next to the United States the British Isles appear to have the highest proportion of practitioners to population.

## THE GENERAL MEDICAL COUNCIL.

THE General Medical Council was established by the Medical Act, 1858, in order "that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners." It consists of eighteen members appointed by the Universities in the United Kingdom having medical faculties; of nine members appointed by the Medical Corporations, such as the Royal Colleges of Physicians and Surgeons; of five members appointed by His Majesty in Council; and of six members directly elected by members of the profession as a whole—a total of thirty-eight. To these are added three dentists who are members of the Dental Board, and are appointed for dental business. Although the eighteen members appointed by the Universities and the five members appointed by His Majesty in Council may all be laymen, only one layman has so far been appointed and that was by the Privy Council in 1926.

The Council's offices are at 44, Hallam Street, Portland Place, London, W.1, and it has Branch Offices at 20, Queen Street, Edinburgh, and 35, Dawson Street, Dublin.

The Council exists for the protection of the public and not of the profession. Its principal duties are, first, to see that no person obtains a qualification without a proper course of study and examination; secondly, to keep the *Medical Register*; and thirdly, to publish the *British Pharmacopœia*. It is the appearance of a name upon the *Medical Register*, and not the possession of a degree or diploma, that constitutes a person "a legally qualified practitioner."

The Council has no power to make rules in regard to the medical curriculum or examination, but it can pass resolutions and make recommendations relating thereto, and if any of these were ignored by the licensing bodies, it would be open to the Council to make representations to the Privy Council, which if it thought fit might order that the qualifications obtained from such Bodies should not be registrable.

The name of any medical practitioner who has been convicted of felony or misdemeanour, or who is proved before the Council itself to have been guilty of "infamous conduct in a professional respect," may be erased from the *Medical Register*.

The Medical Acts prohibit attempts being made to impose restriction as to any theory of medicine or surgery, and, once a practitioner has been trained and tested in the knowledge essential for public safety, he may adopt any "theory" of medicine or surgery in which he honestly

believes. The Medical Acts do not prohibit the practice of medicine by unregistered persons, but if they "wilfully and falsely" assume any title implying registration they are liable to prosecution. In this respect the Medical Acts differ from the Midwives' and the Dentists' Acts, which entirely preclude the practice of midwifery or dentistry by unregistered persons. Unregistered medical practitioners, however, are under certain disabilities, for they cannot recover charges for medical or surgical attendance, etc., in a court of law; they cannot hold an appointment as a medical officer in the Military or Naval Services, or on ships; they cannot give any valid certificate which is required by any Act from a medical practitioner—for example, certificate of death; and they cannot obtain dangerous drugs.

An account of the recommendations that the Council has drawn up in respect of the education of medical students here follows.

### REGISTRATION OF MEDICAL STUDENTS.

The Council recommends that every intending student of medicine should be registered as such at one of its three offices, whose addresses are given below.

Candidates must produce evidence (a) that they have attained the age of 17 years; (b) that they have passed an examination in general education which is accepted for matriculation or entrance to the Faculties of Arts or Pure Science in a university in the United Kingdom; (c) and in addition thereto that they have passed an examination in elementary chemistry and elementary physics conducted or recognized by one of the licensing bodies.

Application for registration should be addressed to the Registrar for the division of the United Kingdom in which the applicant is residing—England and Wales, or Scotland, or Ireland. It must be made on a special form, which can be obtained from one of the offices of the General Medical Council itself or from one of the various licensing bodies and medical schools.

The regulations with regard to registration apply equally to medical and dental students, with the exception that in the case of the latter pupillage with a registered dental practitioner may be regarded as a commencement of professional study, and that applications for registration should be addressed to the London office only.

### PROFESSIONAL EDUCATION.

The rule is that it is only from the date which appears against his name in the *Students Register* that the medical student's career officially begins; thereafter five years at least must pass before he can present himself for the final examination for any diploma which entitles its lawful possessor to registration as a qualified medical practitioner under the Medical Acts; but to meet the circumstances brought about by the dates at which sessions of the medical schools begin and end, the close of the fifth year may be reckoned as occurring at the expiration of fifty-seven months from the date of registration. In any case, the period of five years must be one of bona-fide study; and in every course the following subjects should be included:

- (i) Elements of General Biology, including an introduction to Embryology. This course, if the Licensing Bodies permit, may be taken before registration, and the examination may be passed immediately after registration.
- (ii) Chemistry, Physics, and Biology in their application to Medicine.
- (iii) Human Anatomy and Physiology, including Histology, Elements of Embryology, Biochemistry, and Biophysics.
- (iv) Elementary Bacteriology, prior to regular clinical appointments.
- (v) Pathology, general, special, and clinical, and Morbid Anatomy.
- (vi) Pharmacology and Materia Medica, to be taken concurrently with clinical instruction.
- (vii) Forensic Medicine, Hygiene, and Public Health.
- (viii) Medicine, including Applied Anatomy and Physiology, Clinical Pathology and Therapeutics, Children's Diseases, Acute Infectious Diseases, Tuberculosis, Mental Diseases, Skin Diseases, and Vaccination.
- (ix) Surgery, including Applied Anatomy and Physiology and Clinical Pathology, Anaesthetics, Diseases of the Eye, Ear, Throat, and Nose, Radiology, Venereal Diseases, and Orthopaedics.
- (x) Midwifery and Diseases of Women, including ante-natal conditions and infant hygiene.

The Council recommends that during the last three of the five academic years clinical subjects shall be studied.

The first two years must be passed at a school of medicine recognized by any of the licensing bodies enumerated in the schedule to the Medical Act of 1858, and the remainder must be devoted to clinical work at any public hospital or dispensary at home or abroad which is recognized by a licensing body.

#### SPECIAL CONSIDERATIONS.

The requirements of the General Medical Council in respect of the education of those who desire to enter the medical profession have now been given in outline, but before leaving this part of the subject the steps which the aspirant should take may be rehearsed in their due order:

- (1) Pass an examination in arts;
- (2) Pass an examination conducted or recognized by a licensing body in elementary physics and elementary chemistry;
- (3) Enter himself at a medical school recognized by one of the licensing bodies;
- (4) Obtain registration as a medical student;
- (5) Study for a minimum of five years certain prescribed subjects;
- (6) Meanwhile pass sundry intermediate examinations; and at the end of the fifth year pass a "qualifying examination" which will entitle him to receive from a licensing body a legal authority to practise.

*The Minimum Period.*—It must be remembered that the period of five years is a minimum; more is often required even by the man of good abilities and reasonable industry, and some of the universities prescribe a longer period. Besides these qualities a student, to obtain a registrable qualification in the minimum period of five years, or fifty-seven months, must have a considerable amount of good luck; in other words, he must keep in good health through every term, and never fail at a single examination. Thus, for instance, before presenting himself for any examination he must be "signed up" for the subjects covered by that examination; this means that his teachers have to certify that he has diligently attended the required number of lectures or classes in the subjects in question. If, however, the student happens to be ill during the term when such lectures or classes are taking place he may miss enough of them to make it impossible for him to be signed up. Then, again, should he fail to satisfy the examiners at some examination, he cannot present himself for re-examination for at least three months. This generally entails further consequences, because, apart from the student's success at the next stage in his career being imperilled by the need for restudying the subjects in which he has failed, the Examining Boards usually insist upon a definite interval elapsing between one examination and the next. Further, many Boards have refused to recognize lectures and classes which have been attended before the student has passed the requisite examination in earlier subjects, and the Council now recommends that the professional examinations in anatomy and physiology be passed before the minimum period of three years' subsequent study be entered on; in other words, no clinical study should count as such until these examinations have been successfully completed. Failure at an examination may thus not only mean deferment of the date of examinations, but deferment of the beginning of the student's study of certain subjects. It is thus exceedingly easy for a student to fail to qualify in five years, and, as a fact, the majority of students take longer.

In speaking of the minimum period, it is to be remembered also that that time is only sufficient to gain a registrable qualification, such as a Bachelorship of Medicine or Surgery or the diplomas of the Royal Colleges. Those who wish to take a higher qualification—for instance, the F.R.C.S.Eng.—must prolong their work for another year or more. So, too, must in some cases those who desire to convert their Bachelorship into a Doctorate. This may entail further formal examination, but at some universities the M.D. is obtainable on presentation of a thesis when the Bachelor has attained a certain age and has practised for a certain number of years. However, a student's career proper may be considered, perhaps, to have ended when he obtains his first registrable qualifica-

tion, for while preparing himself for any further tests he can, and usually does, hold some junior appointment which more or less covers his expenses.

#### MEMORANDUM ON STUDENTS' REGISTRATION.

The following memorandum has been drawn up by the Registrar of the General Medical Council as to the procedure for those who desire to be registered as medical or dental students.

The requirements for the registration of medical and dental students are the same, and every intending student should, in his own interest, register as soon as he commences his professional curriculum.

A recognized examination in general education must first be passed. If the student intends to obtain a university degree, he should apply to the university he selects for information as to its matriculation requirements in arts or pure science, or as to any examinations which may be accepted in lieu of its matriculation examination. If the student intends to obtain a qualification from one of the licensing corporations (these are the Conjoint Boards in England, Scotland and Ireland, the Society of Apothecaries of London, and the Apothecaries' Hall of Dublin), any of the examinations indicated below will be accepted. The subjects required are: (1) English, (2) Mathematics (elementary), (3) a language other than English, and (4) an additional subject or subjects, as required by the regulations of the particular examination, to be chosen from the following—namely, History, Geography, Physical Science, Natural Science, Latin, Greek, Hebrew, French, German, or other language accepted by the university for matriculation.

The requirements of the preliminary examination in general education being satisfied, it is then necessary to pass an examination in Elementary Chemistry and Elementary Physics, which is conducted or recognized by one of the licensing bodies—that is, university or corporation. The student should write to the body whose qualification he desires to obtain (a list will be found below) for information in regard to its requirements for this examination.

These two examinations having been passed and the student having attained the age of 17 years, he should apply to one of the universities or one of the medical schools for admission in order to commence therein his professional curriculum. Immediately his course of medical study has been begun, he should apply to the Dean of the school, or to the Registrar of one of the branches of the General Medical Council, for a form of application for registration as a student, and should have it completed and sent in to one of the Branch Councils as soon as possible. There is no fee for this registration. The medical curriculum will extend for at least five years, and the dental curriculum for at least four years, from the date of registration as a student.

A student who has studied the subject of elementary biology at an institution recognized by one of the licensing bodies may, if the body sees fit, be admitted to the professional examination in this subject immediately after his registration as a student. For information in regard to this, he should apply to the body whose medical qualification he seeks.

A dental student may commence his curriculum, if he so desires, as a pupil with a registered dental practitioner; but it is desirable, if possible, that he should commence professional study at a dental school. If, however, he is apprenticed to a dental practitioner, he will have to devote twice as much time to the study of dental mechanics as he would if he had taken this subject in a school. This will have the effect of lengthening the duration of his curriculum to five or six years instead of four.

The addresses of the Branch Registrars are:

General Medical Council, 44, Hallam Street, Portland Place, London, W.1.

Scottish Branch Council, 20, Queen Street, Edinburgh.

Irish Branch Council, 35, Dawson Street, Dublin.

#### Examining Bodies in Preliminary Education.

The following is a list of the officials of the examining bodies in preliminary education, with the names of the examinations in parentheses.

- Registrar, Queen's University of Belfast, Belfast. (Matriculation.)
- Registrar, The University, Bristol. (Matriculation, School Certificate, or Higher School Certificate.)
- Assistant Registrar, The University, Cambridge. (Previous.)
- Secretary, Cambridge Local Examinations, Syndicate Buildings, Cambridge. (School or Higher School Certificate.)
- Director, Central Welsh Examination Board, Cardiff (Senior Certificate.)
- Registrar, University of Dublin School of Physic, Dublin. (Junior Freshman, Special Preliminary, Junior Exhibition, or Examination for first, second, third, or fourth year in Arts.)
- Dean, University of Durham School of Medicine, Newcastle-on-Tyne. (First School Certificate or Matriculation.)
- Registrar, Irish Conjoint Board, Royal College of Surgeons, Dublin. (Preliminary Examination.)
- Registrar, National University of Ireland, Dublin. (Matriculation.)
- Joint Commissioners, Intermediate Education Board of Ireland, 1, Hume Street, Dublin. (Middle and Senior Grade Examinations.)
- Assistant Secretary, Ministry of Education, Belfast. (Senior Grade Intermediate Examination.)
- Academic Registrar, The University of London, South Kensington, London, S.W.7. (Matriculation or General Schools Certificate.)
- Secretary, Northern Universities Joint Matriculation Board, 315, Oxford Road, Manchester. (Matriculation or Senior School Certificate.)
- Registrar, The University, Oxford. (Responsions or Moderations.)
- Secretary, Oxford and Cambridge Schools Examination Board, Schools Examination Office, Balliol College, Oxford. (School or Higher School Certificate.)

Secretary, Oxford Local Examinations, University Press, Oxford. (School or Higher School Certificate.)  
 Secretary, College of Preceptors, Bloomsbury Square, London, W.C.2. (Senior Certificate.)  
 Secretary, Educational Institute of Scotland, 47, Moray Place, Edinburgh. (Preliminary Medical Certificate.)  
 Secretary, Scottish Education Department, 14, Queen Street, Edinburgh (Leaving Certificate.)  
 Secretary, Scottish Universities Entrance Board, 81, North Street, St. Andrews. (Scottish Universities Preliminary Examination.)

#### Licensing Bodies.

The following is a list of the officials of licensing bodies and their addresses:

Secretary, English Conjoint Board, 8, Queen Square, Bloomsbury, W.C.1.  
 Clerk, Society of Apothecaries, Blackfriars, E.C.4.  
 Registrar, The University, Oxford.  
 Registrar, The University, Cambridge.  
 Secretary, University of Durham School of Medicine, Newcastle-on-Tyne.  
 Principal, University of London, South Kensington, S.W.7.  
 Registrar, Victoria University, Manchester.  
 Registrar, The University, Birmingham.  
 Registrar, The University, Liverpool.  
 Registrar, The University, Leeds.  
 Registrar, The University, Sheffield.  
 Registrar, The University, Bristol.  
 Registrar, University of Wales, Cathays Park, Cardiff.  
 Secretary, Scottish Conjoint Board, 49, Lauriston Place, Edinburgh.  
 Dean of the Faculty of Medicine, The University, Edinburgh.  
 Registrar, The University, Glasgow.  
 Registrar, Royal Faculty of Physicians and Surgeons, Glasgow (Dental).  
 Secretary of the Medical Faculty, The University, Aberdeen.  
 Secretary, The University, St. Andrews.  
 Secretary, Irish Conjoint Board, Royal College of Surgeons, Dublin.  
 Registrar, Apothecaries' Hall of Ireland, 85, Merrion Square, Dublin.  
 Medical Registrar, The University, Dublin.  
 Registrar, National University of Ireland, Dublin.  
 Registrar, Queen's University of Belfast, Belfast.

#### Medical Schools.

The following is a list of medical schools and their officials:

Secretary, University of Durham College of Medicine, Newcastle-on-Tyne.  
 Dean of the Medical School, St. Bartholomew's Hospital, London, E.C.1.  
 Dean of the Medical School, Charing Cross Hospital, S.W.1.  
 Dean of the Medical School, St. George's Hospital, S.W.1.  
 Dean of the Medical School, Guy's Hospital, S.E.1.  
 Dean of the Medical School, King's College, Strand, W.C.1.  
 Dean of the Medical School, King's College Hospital, S.E.5.  
 Dean of the Medical School, London Hospital, E.1.  
 Dean of the Medical School, St. Mary's Hospital, W.2.  
 Dean of the Medical School, Middlesex Hospital, W.1.  
 Dean of the Medical School, St. Thomas's Hospital, S.E.1.  
 Dean of the Medical School, University College Hospital, W.C.1.  
 Dean of the Medical School, Westminster Hospital, S.W.1.  
 Registrar, School of Medicine for Women, 7, Hunter Street, W.C.1.  
 Secretary, Bedford College for Women, N.W.1.  
 Secretary, Royal Holloway College, Virginia Water.  
 Dean of the Medical School, University College, Aberystwyth.  
 Dean of the Medical School, University College, Bangor.  
 Dean, University College of South Wales, Cardiff.  
 Dean of the Medical School, Welsh National School of Medicine, Swansea.  
 Dean of the Medical School, University College, Dundee.  
 Dean, School of Medicine of the Royal Colleges, Edinburgh.  
 Dean, St. Mungo's College, Glasgow.  
 Dean, Anderson's College Medical School, Glasgow.  
 Mistress, Queen Margaret College, Glasgow.  
 Registrar, School of Physick, Trinity College, Dublin.  
 Registrar, University College, Cork.  
 Registrar, University College, Dublin.  
 Registrar, University College, Galway.

#### Dental Schools.

The following is a list of dental schools and their officials:

Dean of the Dental School, Dental Hospital, Birmingham.  
 Dean, Royal Infirmary, Bristol.  
 Dean, General Hospital, Bristol.  
 Dean, Dental Hospital of Ireland, Dublin.  
 Dean, Dental Hospital, Dundee.  
 Dean, Edinburgh Dental Hospital, Edinburgh.  
 Dean, Glasgow Dental Hospital, Glasgow.  
 Dean, Dental Hospital, Leeds.  
 Director of Dental Education, Dental Hospital, Liverpool.  
 Secretary of the Dental School, Guy's Hospital, London, S.E.1.  
 Dean of the Dental School, London Hospital, E.1.  
 Dean, National Dental Hospital, Great Portland Street, W.1.  
 Dean, Royal Dental Hospital, Leicester Square, W.C.2.  
 Dean, Manchester Dental Hospital, 192, Oxford Road, Manchester.  
 Dean, Dental Hospital, Newcastle-on-Tyne.  
 Dean of the Dental School, Royal Hospital, Sheffield.  
 Registrar, Royal College of Surgeons in Ireland, Dublin.  
 Dean of the Dental Department of any University of the United Kingdom.

#### PROFESSIONAL EXAMINATION.

##### The Council's Recommendations.

The following recommendations of the General Medical Council in regard to professional examinations for medical and surgical qualifications were adopted in May, 1922:

1. In order to secure due continuity and sequence in medical study, two or more Professional Examinations in the earlier subjects should be held antecedently to the Final Examination in Medicine, Surgery, and Midwifery.

2. Three years at least should intervene between the date of passing the Professional Examination in Anatomy and Physiology and that of admission to the Final Examination in Medicine, Surgery, and Midwifery.

3. A candidate remitted in any subject of a Professional Examination should, before he is readmitted to examination therein, be required to produce satisfactory evidence that he has, during the interval of remission, pursued the study of the

subject in which he was rejected. Candidates who obtain less than 50 per cent. of the marks in any subject should be remitted for a longer period than three months.

4. In all the Professional Examinations sufficient time should be assigned to practical work, in order to test the thoroughness of the candidate's knowledge and to encourage practical methods of study.

5. Candidates in all their examination work should be carefully supervised.

6. Two examiners should always participate in the oral examination of a candidate, except in subordinate parts of practical examinations.

7. In all written examinations the questions in each subject should be submitted for the approval of all the examiners in that subject.

8. In all written examinations an average of at least half an hour should be allowed for a candidate to answer each question.

9. It is desirable that examiners, and in particular those for the Final Examination in Medicine, Surgery, and Midwifery, should be appointed or re-elected for at least three consecutive years.

10. Whatever may be the system of marking, the percentage for a pass in each subject should not be less than 50.

11. In the regulations for the several examinations it should be provided that examiners, in assessing marks, be empowered to take into account the duly attested records of the work done by the candidate throughout his course of study in the subject of the examination.

12. The Final Examination in Medicine, Surgery, and Midwifery, with the exception of the Clinical and Practical Examination in Midwifery and Gynaecology, must not be passed before the close of the fifth academic year of medical study.

13. The three portions of the Final Examination in Medicine, Surgery, and Midwifery should not be further subdivided into sections which may be entered for or passed separately.

14. Compensation in respect of marks as between the three different portions of the Final or Qualifying Examination—namely, Medicine, Surgery, and Midwifery—is contrary to the intention of the Medical Act (1836).

15. The Final Examination should include clinical and practical examinations in Midwifery and Gynaecology.

16. The clinical examination in Medicine, Surgery, and Midwifery should be held in properly equipped hospitals or examination halls well provided with suitable patients.

17. In the examinations in clinical medicine at least one hour, and in clinical surgery at least half an hour, should be allowed to the candidate for the examination of, and report on, his principal case.

18. In Medicine, in Surgery, and in Midwifery, no candidate should be allowed to pass who fails to obtain 50 per cent. of the aggregate marks assigned to the whole examination; or who fails to obtain 50 per cent. of the marks assigned to the clinical examination; or who fails to obtain 40 per cent. of the aggregate of the marks assigned to the written and oral examination. In Midwifery, where a clinical examination is not held, the duly attested records of the work done by the candidate in clinical midwifery must be presented to the examiners for assessment in the Final Examination; and no candidate should be allowed to pass who fails to obtain 50 per cent. of the aggregate marks assigned to Clinical and Practical Midwifery and Gynaecology.

19. The Final Examination should include the examination of secretions, the testing of urine, clinical microscopy, and prescription writing, and there should always be an oral examination in Medicine, Surgery, and Midwifery, which should include an examination on pathological specimens.

20. At the Final Examination each candidate should be submitted to a practical and oral examination in Pathology (macroscopic and microscopic), unless this has been included in a Professional Examination preceding the Final Examination.

21. Whatever be the method of entry for the Final Examination all candidates should be required to complete the three portions of the Final Examination within a period of nineteen months.

## The English Universities.

THERE are eleven universities in England and Wales, and some account of each of them follows. They all have now fully developed medical faculties. Until recently the only exception was the University of Wales, whose constituent colleges are those of Aberystwyth, Bangor, Cardiff, and Swansea. This university grants degrees, and has laid down a six years' curriculum for candidates for the M.B. and B.Ch. degrees, and it now provides, at the Welsh National School of Medicine at Cardiff (see page 426), instruction in all the subjects of the medical curriculum.

## UNIVERSITY OF OXFORD.

THE professional degrees conferred by this university are those of Bachelor of Medicine (B.M.), Bachelor of Surgery (B.Ch.), Doctor of Medicine (D.M.), and Master of Surgery (M.Ch.). It also grants a Diploma in Public Health and a Diploma in Ophthalmology. On receiving the B.M. the candidate is entitled to registration by the General Medical Council. In favourable circumstances this degree and the B.Ch. may be obtained in six or seven years from matriculation. Before receiving either, the candidate must have taken a degree in arts (B.A.), for which three years' residence within the university is necessary. This, however, does not necessarily mean deferment of professional study for that period, for the subjects chosen for the arts course may be the same as those in which examinations would in any case have to be passed for the medical degree.

In accordance with a statute which came into force on October 7th, 1920, women may be matriculated and admitted to degrees in the university. The statute is retrospective under certain conditions. Before matriculation a woman must have been admitted as a member of one of the five societies of women students (Lady Margaret Hall, Somerville College, St. Hugh's College, St. Hilda's Hall, or the Society of Oxford Home Students). Women members of the university are admitted to all degrees, except those in divinity, under the same conditions as those laid down for men in regard to examinations, courses of study, and fees, and under corresponding conditions as to residence at the university. Among the university diplomas open to women are those in anthropology, ophthalmology, and public health.

A candidate may obtain the B.A. degree in either of the following ways, of which the former constitutes the normal course for medical students:

(a) By passing Responsions (or one of the examinations which are accepted as equivalent), the Scripture examination, some of the preliminary examinations in the Natural Science School,<sup>1</sup> or the Honour School of Mathematics in the first public examination; and one of the final honour examinations—the Final Honour School of Natural Science (Physiology) is that usually taken.

(b) By passing Responsions (or one of the examinations which are accepted as equivalent), Moderations, a Scripture examination, or, in the event of a candidate objecting, an examination on some substituted book; and the Final Pass School in three subjects, two of which may be the same as two of the preliminary examinations in natural science.<sup>2</sup>

Responsions and the preliminary examinations in Natural Science may be passed before a candidate is a member of the university<sup>3</sup>; Moderations and Scripture can be passed in or after the second term; the final pass school may be taken any time after Moderations; a final honour school may be taken at the end of the third or fourth academical year—that is, within nine or twelve terms respectively; the preliminary examinations of the Natural Science School may be taken as soon as Responsions has been passed or exemption obtained.

## PROFESSIONAL DEGREES.

To obtain the B.M., B.Ch. degrees the candidate must first pass in four of the subjects of the Preliminary Examination of the Natural Science School—namely, physics, chemistry, zoology, and botany.

He then has two further examinations to pass—the First B.M. and the Second B.M. These take place twice a year, the first on the Thursday, the second on the Wednesday, of the eighth week of Michaelmas and Trinity terms. Every candidate at the First M.B. is examined in human anatomy, in physiology, and in organic chemistry, but is excused from physiology if he has obtained a first or second class in the Honour School of Physiology, and from organic chemistry if he has satisfied the examiners in Part I of the Honour School of Chemistry. Once he has passed this examination he can, on production of certain certificates, be examined as soon as he pleases in pathology, forensic medicine and hygiene, materia medica, and pharmacology (subjects of the second examination), but cannot present himself for the remaining subjects—medi-

cine, surgery, and midwifery—until the eighteenth term from the day of his matriculation *unless he be already a registered medical practitioner*, and not until a period of at least thirty-three months has elapsed from the date of his passing the first examination, and he must pass in all the three subjects at one and the same time.

Before admission to the second B.M. examination the student must produce certificates of instruction from a medical school recognized by the university, of having acted as clinical clerk and dresser, each for six months, and as *post-mortem* clerk for three months, of attendance on labours, of instruction in infectious and mental diseases and ophthalmology, and of proficiency in vaccination and the administration of anaesthetics.<sup>4</sup> He must also produce certificates of attendance in laboratory courses in pathology, bacteriology, and pharmacology, either in Oxford or in a recognized medical school.

## D.M. AND M.Ch. DEGREES.

A Bachelor of Medicine who wishes to proceed to the D.M. must have entered his thirtieth term and must present a dissertation for approval by the appointed examiners on a subject previously approved by the Regius Professor of Medicine. If a candidate for the M.Ch. he must have entered his twenty-first term and must pass an examination, which is held in June.

Examinations for the Diploma in Public Health are held in Trinity and Michaelmas<sup>4</sup> terms; that for the Diploma in Ophthalmology is held annually in March. For the Diploma in Ophthalmology attendance on a twelve months' course of clinical ophthalmology in hospitals or institutions recognized for the purpose by the Board of the Faculty of Medicine, and on a course of instruction in Oxford lasting two months, is obligatory. Candidates must have their names on the *Medical Register* of the United Kingdom, unless, being Bachelors or Doctors of Medicine of universities outside the United Kingdom, they have obtained special permission from the Board of the Faculty of Medicine.

## TEACHING.

The several colleges provide their undergraduate members with tutors for all examinations up to the B.A. degree. In addition, the university provides certain courses of instruction, including lectures, demonstrations, and practical work, which cover all the subjects of the Preliminary Examination and First B.M., and those of the Final Examination.

## SCHOLARSHIPS.

Most colleges grant scholarships open to intending medical students of £80 a year, tenable for four years, in natural science, chemistry, physics and biology. Exhibitions of varying value are also awarded in these subjects. At two colleges (University and Pembroke) there are medical entrance scholarships of £100 a year. Particulars can be obtained on application to the college tutors. Scholarships for women are also offered by the various women's colleges, from the principals of whom details of the examinations may be obtained. A Radcliffe Travelling Fellowship of £300 a year, tenable for two years, is conferred annually; candidates must have taken the B.M. degree. A Philip Walker Studentship in Pathology of £200 a year, tenable for two years, is awarded biennially for the encouragement of research; the holders are the Rolleston Memorial Prize and the Radcliffe Prize for research in natural science (including physiology). Theodor Williams Scholarships in Anatomy, Physiology, and Pathology, of the value of £50 each, tenable for two years. A Radcliffe Scholarship in Pharmacology of £50 for one year, open to the University, is awarded annually by the Master and Fellows of University College. A Burney Yeo King's College Hospital Scholarship of £80 is awarded annually.

## FEES.

An annual fee of £4 10s. is paid to the university for the first four years, being reduced to £1 when the B.A. has been taken. For the degree the fees are: the B.A., £7 10s.; the B.M. and B.Ch., £14; the D.M., £25; the M.Ch., £12. College fees, varying in amount, are paid for the first four years of membership and in taking degrees. Tuition fees vary from £21 to £30. The minimum annual cost of living during the three university terms may be regarded as not less than £180, or for women not less than £140.

For further information application may be made to Dr. E. W. Ainley Walker, Dean of the School of Medicine, University of Oxford.

<sup>1</sup> For the certificates that will be required from candidates amenable to the new Regulations of the General Medical Council, see *Examination Statutes*, Clarendon Press, Oxford, 1925 edition.

<sup>4</sup> The examination in Michaelmas Term is at present suspended.

<sup>1</sup> The four subjects of the medical preliminary examinations are four of the subjects in the natural science preliminary, and can be commenced directly after passing Responsions.

<sup>2</sup> Membership is constituted by matriculation and by becoming either a member of a College or a Hall, or a non-collegiate student.

## UNIVERSITY OF CAMBRIDGE.

The professional degrees given by this university are those of Bachelor of Medicine (M.B.) and Bachelor of Surgery (B.Chir.), each of which entitles the possessor to admission to the Register by the General Medical Council, and the higher degrees of Doctor of Medicine and Master of Surgery. It also grants Diplomas in Tropical Medicine, in Public Health, in Hygiene, in Psychological Medicine, and in Medical Radiology and Electrology to medical practitioners; not necessarily graduates of the university. Information regarding these diplomas will be found in later sections under the headings Tropical Medicine, Psychological Medicine, Public Health, and Radiology. A candidate for the M.B., B.Chir. degrees need not possess a degree in arts; it is sufficient if he has passed the Previous examination or some other examination accepted by the university as its equivalent. Most students, however, are advised to take the B.A. degree, preferably by obtaining honours in the Natural Science Tripos at the end of their third year. Under the new regulations the attainment of a sufficient standard in chemistry or in physiology in this Tripos will secure exemption from the corresponding tests in the First and Second M.B. examinations. Women students, members of Girton or Newnham College, are now admitted to the M.B. examinations.

## PROFESSIONAL EXAMINATIONS

To obtain the M.B. degree the candidate must pass three examinations; those who are finally successful may receive the B.Chir. degree (which is a complete registrable qualification) without further examination.

**First M.B.**—This comprises (1) general and inorganic chemistry, (2) mechanics, (3) physics, (4) elementary biology. The parts may be taken together or separately. In either case the candidate before admission to examination must have satisfied the requirements in respect of the Previous examination and paid the registration fee. Certain exemptions from the First M.B. examination are allowed; the regulations may be obtained from the Registrar. The complete examination is held twice a year—in October and June; an additional examination, in Parts 2 and 4, is held in December.

**Second M.B.**—This examination comprises: Part I, organic chemistry; Part II, human anatomy and physiology; Part III, elementary pharmacology, including pharmaceutical chemistry and the elements of general pathology. No student is admitted to the first part of the second examination until he has passed the first part of the first examination. No student is admitted to the second part of the second examination until he has passed all parts of the first examination. No student shall be admitted to the third part of the second examination until he has passed the first and second parts of the second examination. The candidate must be signed up in all three subjects and have dissected for one academic year. The examinations for Part I and II are held in December and June; that for Part III in October and April.

**Third M.B.**—This is divided into two parts, to neither of which is the candidate admitted until he has passed the examinations previously mentioned. A candidate for the first part, which deals with the principles and practice of surgery (including special pathology) and midwifery and diseases peculiar to women, must have completed five years of medical study and be signed up in these subjects and have completed two years and a half of hospital practice. Before admission to the second part the candidate must have completed five years of medical study, and be duly signed up in all subjects and have completed three years of hospital practice. He must also possess certificates showing that he has fulfilled all the recommendations as well as the requirements of the General Medical Council. The examination is in the principles and practice of physic (including diseases of children, mental diseases, and medical jurisprudence), pathology (including hygiene and preventive medicine), and pharmacology (including therapeutics and toxicology). The Third M.B. examinations are held twice a year—in June and December.

**Act for the M.B.**—Before receiving his M.B. degree a candidate who has been successful at the final M.B. exam-

inations has to write a thesis. This he reads in public on an assigned day, and is then questioned concerning it and other subjects of medicine by the Regius Professor of Physic. If approved at this test he is then certified as having "kept the Act" satisfactorily, and in due course receives his degree. Medical degrees may be taken in absence by those living abroad, the candidate sending to the Regius Professor of Physic a dissertation, which is laid before the Degree Committee.

## THE HIGHER DEGREES.

The M.D. degree may be taken by a Bachelor of Medicine of three years' standing (and a Master of Arts of four years' standing who has completed the course required for M.B.) after writing a thesis approved by the M.D. Degree Committee, and keeping a further Act, at which he reads his thesis and is examined thereon. Previously to the Act being kept a topic taken from the general subject of his thesis (whether it be physiology, pathology, pharmacology, practice of medicine, State medicine, or the history of medicine) is submitted to the candidate, on which he is required to write an extempore essay.

The M.Chir. degree may be granted to a candidate who has qualified for the B.Chir. at least two years previously; he is then examined in pathology, surgery, surgical anatomy, and surgical operations. The tests are partly in writing, partly oral, and partly practical: they include the writing of an extempore essay.

## FEES.

In addition to college fees, tutorial fees, and the expense of living, the following examination fees are payable: First M.B., £5 5s.; Second M.B., £6 6s.; Third M.B., £10 10s. For schedules referring to the examinations, lists of schools recognized by the university, and other information, application should be made to the University Registry, Cambridge.

## UNIVERSITY OF LONDON.

UNDER the regulations of the University of London the degrees obtainable in the Faculty of Medicine are those of Bachelor of Medicine and Surgery, Master of Surgery in two branches, and Doctor of Medicine in six different branches. The university has its own matriculation examination, and this is of so peculiar a kind that candidates should obtain and carefully study the booklets relating to it. The matriculation examination is open to any person, of either sex, who has attained the age of 16. It is held in January, June, and September, and lasts four days; the first two take place both in London and in certain provincial centres; the September examination is held in London only.

In no circumstances is a degree granted to anyone in less than three years after the date at which he passed the Matriculation Examination or obtained registration in some other way; and, unless they are already registered medical practitioners of a certain age and standing, all medical students must pass not less than five and a half years in professional study subsequent to matriculation, of which the last three years must be spent at a school of advanced medical studies.

## PROFESSIONAL EXAMINATIONS.

**M.B., B.S.**—There are three examinations, the last two being subdivided. They are held twice a year.

The First Examination (held in July and December) covers inorganic chemistry, general biology, and physics, there being two papers, a practical test, and a possible oral test in each subject. The names of successful candidates are placed in alphabetical order, with a note as to any subject in which a candidate has distinguished himself or herself.

The Second Examination is held in March and July. Part I cannot be passed within six months of the passing of the First Examination. It covers organic and applied chemistry, the candidate's knowledge being tested as in the earlier examination. It is a pass examination, but a mark of distinction may be won. Candidates for Part II must have passed the First Examination at least eighteen months previously, besides having completed Part I of the Second Examination. The subjects are anatomy, physiology, and pharmacology, the tests being written, oral, and practical. Candidates who fail in one subject may sit for re-examination in that subject alone if the examiners think fit.

No candidate is admitted to the Third M.B., B.S. Examination within three academic years from the date of Second Examination: The subjects are therapeutics and mental diseases), pathology, forensic medicine and hygiene, surgery, and midwifery and diseases of women. They may be divided into two groups, one comprising medicine, pathology, forensic medicine, and hygiene, and the other surgery and midwifery and diseases of women. Either group may be taken first at the option of the candidate, or the groups may be taken together. Only candidates who show a competent knowledge of all the subjects comprising a group are passed. There is no separate examination held for honours, but the names of successful candidates are divided into an honours list and a pass list, and a university medal may be awarded the candidate who has most distinguished himself in the whole examination.

#### THE HIGHER DEGREES.

**M.D.**—An examination for the M.D. is held twice yearly—in December and July. Every candidate must have passed the examination for the M.B., B.S., unless he became M.B. before May, 1904. He may present himself for examination in any one of the following branches: (1) medicine, (2) pathology, (3) mental diseases and psychology, (4) midwifery and diseases of women, (5) State medicine, (6) tropical medicine, and, if he wishes, may pass also in another branch at a subsequent examination.

The period that must elapse between acquiring the M.B. and sitting for the M.D. in any branch varies between one and two years, according to the nature of the candidate's previous work, and in all cases evidence must be afforded of special study of the subject chosen; both written and practical examinations must be passed, though exemptions can be obtained from the former in exceptional circumstances. In each branch the scheme of examination is the same: two papers on its special subject, a paper on an allied subject—for example, medicine in the case of branch (4), pathology in branch (1)—an essay on one of two suggested topics connected with the special subject, and a clinical or other practical test. In any branch of the M.D. Examination a gold medal of the value of £20 may be awarded.

**M.S.**—The regulations with regard to the Mastership in Surgery are of a corresponding kind, but there are only two branches in which it may be obtained—General Surgery and Dental Surgery.

#### FEES.

The examination fees have been raised from pounds to guineas for all examinations held after September 1st, 1918. For Matriculation: 2 guineas for each entry. First Examination: 5 guineas for each entry to the whole examination. For re-examination in one subject the fee is 2 guineas. Second Examination, Part I: 2 guineas for the first and each subsequent entry. Second Examination, Part II: 8 guineas for each entry to the whole examination. For re-examination in one subject the fee is 4 guineas. M.B., B.S. Examination: 10 guineas for each entry to the whole examination, and 5 guineas for examination or re-examination in either group. M.D. and M.S. Examinations: 20 guineas, and 10 guineas on re-examination.

Inquiries should be addressed to the Registrar, the University of London, South Kensington, S.W.7.

#### UNIVERSITY OF BIRMINGHAM.

This university confers medical and surgical degrees—namely, M.B., Ch.B., M.D., and Ch.M.—and also diplomas and degrees in State medicine and dentistry. It has a plan, too, by which, extending his study to six instead of five years, the M.B., Ch.B. candidate may become a Bachelor in Science as well. Of the five years' curriculum, the first four must be spent, as a rule, at the university itself, the fifth being passed at any approved school or schools. Occasionally, however, the Senate will reduce the period of enforced residence to three years and exempt from the First M.B. (Part I) those who have passed elsewhere an examination considered to be its equivalent. A degree of Ph.D. is also conferred for research study in medicine under special regulations. Candidates must be graduates in medicine of a recognized university.

Students entering the Medical Faculty for the M.B., Ch.B. degrees must have passed—

(1) Either (a) the matriculation examination of the Joint Board of the Universities of Manchester, Liverpool, Leeds,

Sheffield, and Birmingham; or (b) some other examination recognized as equivalent to the matriculation. Candidates for medical degrees are recommended to take Latin and a science subject—chemistry or physics—at the matriculation examination, although these subjects are no longer compulsory. The matriculation examination of the Joint Board is held in July and September. The regulations and the list of examinations accepted in lieu thereof will be sent on application to the Secretary to the Board, Joint Matriculation Board, 315, Oxford Road, Manchester.

(2) A recognized pre-medical examination in the subjects of chemistry and physics—for example, the Higher School Certificate of the Joint Matriculation Board; or a candidate may attend courses for pre-medical year in the university, October to June, taking chemistry and physics; and biology (optional).

#### PROFESSIONAL EXAMINATIONS.

The candidate for the M.B., Ch.B. degrees has five examinations to pass. In the second and final examinations the candidate must pass in all the prescribed subjects or undergo the whole examination again.

The First M.B. (Part I) deals with elementary biology, and physical and organic chemistry. The First M.B. (Part II) deals with anatomy and physiology, and the student must pass in both simultaneously. The Second M.B. deals with pathology and bacteriology, materia medica, and pharmacy. The Third M.B. takes place at the end of the fourth year, the subjects being forensic medicine, toxicology, public health, and pharmacology and therapeutics.

**Final M.B.**—This comprises medicine, surgery, midwifery and diseases of women, ophthalmology, and mental diseases. The candidate, in addition to more ordinary certificates, must be prepared with a certificate of having acted as a *post-mortem* clerk for three months, and received special instruction in anaesthetics and clinical instruction in diseases peculiar to women, asylum ward work, ophthalmology, children's diseases, venereal diseases, ear and throat and skin diseases, etc. In respect to ophthalmology he must show that he has learnt refraction work. He also has to present to the examiners at the time of his examination a short written commentary on a gynaecological subject or case investigated during the period of gynaecological clerking, and certificates drawn up by himself regarding four actual cases of lunacy and notes on two others.

**M.D.**—An ordinary candidate for this degree must be a M.B., Ch.B. of not less than one year's standing. He presents an original thesis for approval, and then passes a general examination in the principles and practice of medicine. From the latter the Board of Examiners may exempt a candidate whose thesis is of exceptional merit. The regulations respecting the Ch.M. are of the same general character. Subject to certain requirements as to special research or other post-graduate study, graduates of other universities may obtain the M.D. and Ch.M. in the same way as holders of the Birmingham M.B., Ch.B.

#### FEES.

The fee for matriculation is £2 (payable to Joint Matriculation Board): £2 10s. for pre-medical examination (if taken in university), and £2 10s. for each of the first four professional examinations: M.B., Ch.B. degree fee, £10; M.D. and Ch.M. examinations, £12 10s. each. For further particulars application should be made to the Dean of the Medical Faculty, University of Birmingham.

#### UNIVERSITY OF BRISTOL.

In the Faculty of Medicine the following degrees are conferred: Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There are also the following diplomas: diploma in public health (D.P.H.), diploma in dental surgery (L.D.S.), and diploma in veterinary State medicine. All candidates for degrees in medicine, surgery, and dentistry are required to pass an examination called the School Certificate Examination, or to pass such examination as may be regarded as equivalent by the Senate. All courses, degrees, and diplomas are open to men and women alike.

**Conjoined Degrees of Bachelor of Medicine and Bachelor of Surgery.**—Candidates must be not less than 21 years of age and have pursued the courses prescribed by univer-

sity regulations during not less than five years after passing the first examination in chemistry and physics, of which three shall have been passed in the university, and two of these three subsequent to passing the second examination. All candidates for the degrees of M.B., Ch.B. are required to satisfy the examiners in the several subjects of three examinations.

*The First Examination.*—The subjects of examination are: chemistry (inorganic), physics, and biology, the courses pursued being those for the time being approved for the intermediate part of the B.Sc. curriculum. This part of the curriculum shall extend over one year. (Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the First Examination and will be regarded as having completed one year of study.)

*The Second Examination.*—The subjects of examination are: organic chemistry and elementary anatomy (Part I) and advanced anatomy and physiology (Part II). Parts I and II may be passed separately or together.

*The Final Examination.*—The subjects of examination are: materia medica and pharmacy, pharmacology and therapeutics, general pathology, morbid anatomy, and bacteriology (Part I); special pathology, forensic medicine, toxicology, and public health, obstetrics (including diseases of women), surgery (systematic, clinical, practical, and operative), medicine (systematic, clinical, and practical, including mental diseases) (Part II). The subjects included in Part II may be taken in two groups—namely, Group I: surgery and obstetrics; Group II: medicine, public health, special pathology, forensic medicine, and toxicology. Candidates may pass Parts I and II together or separately, and the two groups of Part II may likewise be taken together or separately. Forensic medicine and toxicology may be taken either with Part I or with Group II of Part II.

*Degree of Doctor of Medicine.*—Candidates must be Bachelors of the university of not less than two years' standing as such, and may elect either (1) to pass an examination in general medicine, or (2) to pass an examination in State medicine, or (3) to present a dissertation. The candidate who elects to pass the examination in State medicine must hold a Diploma in Public Health of some university or college, and the candidate who elects to present a dissertation may be examined in the subject thereof.

*Degree of Master of Surgery.*—Candidates shall be Bachelors of not less than two years' standing as such, during which period they shall have attended the surgical practice of an institution approved for the purpose. They shall pass an examination in surgical anatomy, pathology, and bacteriology, and operative, clinical, and general surgery, and present to the university a dissertation on some subject of surgery. The degree may be taken also in general surgery, and a special subject—for example, oto-rhino-laryngology, ophthalmology, and gynaecology.

*Diploma in Public Health.*—Candidates must be at least 23 years of age, be fully registered medical practitioners of not less than two years' standing as such, and have passed the examination prescribed by regulation. The examination is divided into two parts.

## UNIVERSITY OF DURHAM.

To its own undergraduates, who may be of either sex, this university grants the degrees of Bachelor of Medicine and Bachelor of Surgery (M.B., B.S.), and Doctor of Medicine (M.D.), Master of Surgery and Doctor of Surgery (M.S. and D.Ch.), Bachelor of Hygiene, Doctor of Hygiene, and Bachelor of Dental Surgery and Master of Dental Surgery (B.D.S. and M.D.S.); it also grants diplomas in public health, psychiatry, and dental surgery. The university accepts the Durham University School Certificate Examination (if the required subjects are passed with credit) for matriculation purposes, but also accepts the tests of a considerable number of other educational bodies as a full or partial equivalent. A list may be obtained on application. In addition to satisfying the matriculation requirements of the university,

every student must (1) pass a pre-registration examination in physics and inorganic chemistry conducted or recognized by the university, and (2) be registered on the books of the General Medical Council. To become a graduate, however, at the university it is not necessary to pass the major portion of the five years' curriculum within its precincts. It is sufficient if, before he presents himself for his final examination, the candidate has passed at least one year in study at the University of Durham College of Medicine, Newcastle-upon-Tyne, including the practice of the Royal Victoria Infirmary in the same city. The earlier examinations may be passed while the student works elsewhere.

### PROFESSIONAL EXAMINATIONS.

There are four professional examinations for the M.B., B.S. degrees. The First, Second, and Third Examinations are held in March, June, and December, and the Final Examination in June and December. The first deals with biology and organic chemistry; the second with anatomy and physiology; the third with pathology, bacteriology, materia medica, pharmacology, therapeutics, and pharmacy, medical jurisprudence, and public health. At the final M.B., B.S. the candidate is examined in medicine, clinical medicine and therapeutics; surgery and clinical surgery; midwifery and diseases of women and children; clinical and practical midwifery and gynaecology; and clinically in psychological medicine, diseases of the throat, nose, and ear, diseases of the skin, diseases of the eye, and diseases of children.

*M.D.*—A Bachelor of Medicine who wishes to proceed to this higher degree must be of at least two years' standing, and must comply with the regulations printed in the Calendar of the College of Medicine. If the candidate is not a M.B. of the university, he must be a practitioner of fifteen years' standing, 40 years of age, and submit to special tests. (See under Degrees for Practitioners, p. 447).

*M.S.*—Candidates for this degree must have been engaged in practice for at least two years subsequent to becoming M.B., B.S. Durham. They are submitted to an examination which covers the whole range of surgical knowledge.

*D.Ch.*—The university grants also the degree of Doctor of Surgery. Candidates for this degree must be registered medical practitioners, not less than 24 years of age. They must devote three years, subsequent to obtaining a registrable qualification, to the study of surgery and ancillary subjects; one at least of the three years must be spent in the university. The candidate must submit to the professor of surgery the course of study he proposes to follow, and this course must be approved by the Board of the Faculty of Medicine.

One year must be devoted mainly to work in the departments of anatomy, physiology, pathology, and bacteriology, and the candidate must submit evidence of having so worked. Not less than six months of another year must be spent as resident surgeon in a recognized teaching hospital, and the rest of the year in the study of surgery in a recognized medical centre. Not less than six months of one of the three years must be spent in surgical study abroad.

### Degree of Bachelor of Hygiene and the D.P.H.

No candidate is admitted to the final examination for the degree of B.Hy. unless he is a Bachelor of Medicine and Surgery, of not less than two years' standing, of a recognized university.

No candidate is admitted to the final examination for the D.P.H. unless he is a registered medical practitioner of not less than two years' standing.

The course of study for the B.Hy. and D.P.H. extends over a period of not less than twelve calendar months subsequent to the attainment of a registrable qualification. Candidates for the B.Hy. must attend this course at the University of Durham; candidates for the D.P.H. may attend it at the University of Durham or at any medical school or institution which is recognized by the university.

The examination for the diploma or degree consists of Part I and Part II, each of which extends over not less than two days, and is conducted by examiners specially qualified. A candidate must pass in all the subjects of Part I before being admitted to examination for Part II. In Part I, and also in Part II, a candidate must pass in all the specified subjects at one time.

The examination for Part I is practical, written, and oral, and includes the following subjects: bacteriology and parasitology (including medical entomology); chemistry and physics; and

meteorology and climatology, in relation to public health. Candidates are not admitted to examination for Part I until after they have completed the prescribed courses of instruction in the subjects thereof.

The examination for Part II includes the following subjects: hygiene and sanitation (including sanitary construction); epidemiology and infectious diseases; sanitary law and vital statistics; public health administration. The examination is written and oral, and includes practical examinations in infectious diseases; food inspection, inspection of premises—dwellings, factories, workshops, schools, etc. Candidates are not admitted to examination for Part II until after they have completed the prescribed courses of instruction in the subjects thereof.

#### Doctor of Hygiene.

Candidates for the degree of Doctor of Hygiene must be Bachelors of Hygiene of two years' standing, and are required to satisfy the examiners that they have conducted original research in the subject of public health.

#### Diploma in Psychiatry.

Candidates must be registered medical practitioners, and, unless qualified before January 1st, 1911, must have attended, subsequently to passing their qualifying examinations, courses of instruction in: (a) anatomy; (b) physiology; (c) pathology; (d) bacteriology; (e) psychology and experimental psychology; (f) clinical neurology; (g) psychiatry; (h) clinical psychiatry. The examination consists of two parts, namely: (1) anatomy, physiology, pathology, and bacteriology; (2) psychology and experimental psychology, neurology, and psychiatry (systematic and clinical); and candidates may present themselves for the whole examination or for either part separately.

#### Licence and Degrees in Dental Surgery.

**L.D.S.**—Every dental student must, at the commencement of his studentship, be registered in the manner and under the conditions prescribed for medical students.

The First Examination consists of three parts, which may be passed separately: Part 1, organic chemistry; Part 2, biology; Part 3, theoretical dental mechanics, dental metallurgy (theoretical and practical). Second Examination: Anatomy, physiology (including biochemistry and biophysics), dental anatomy, and dental histology. Third Examination: Pathology and bacteriology, practical dental mechanics, dental materia medica and therapeutics. Final Examination: Medicine, surgery, dental surgery and pathology, orthodontics, operative dental surgery and dental prosthetics, and anaesthetics.

A candidate before presenting himself for examination is required to furnish certificates of instruction in the required subjects, attended after registration as a dental student at recognized colleges or medical schools.

**Degree of Bachelor of Dental Surgery.**—1.—Students taking their complete course of instruction in the university must pass the same matriculation tests as medical students, and the same pre-registration examination in inorganic chemistry and physics. After registration students must spend five years in the university. They must attend the practice of the Newcastle-upon-Tyne Dental Hospital for not less than two and a half years; six months of this time must be devoted to the study of the higher branches of dental science. There are four examinations. The subjects of the examinations are as follows: *First*: Biology, organic chemistry, and dental mechanics and metallurgy. *Second*: Anatomy, physiology, dental anatomy, and histology. *Third*: Pathology and bacteriology, dental materia medica and therapeutics, and practical and dental mechanics. *Final*: Medicine, surgery, dental surgery and pathology, orthodontics and operative dental surgery. In this subject knowledge of a much higher standard, and more advanced practical work, are required than for the Licence in Dental Surgery.

2.—Candidates possessing a Licence in Dental Surgery of a British university must study for at least one year in the university. During such year they must (a) attend a course of instruction in pathology and bacteriology, and (b) spend at least six months in the Newcastle-upon-Tyne Dental Hospital in the study and practice of the higher branches of dental science. They must also pass the third and final examinations for the degree of Bachelor of Dental Surgery.

**Degree of Master of Dental Surgery.**—Every candidate for this degree must be a Bachelor of Dental Surgery of the university of not less than two years' standing, and present an essay embodying original work and research in some subject connected with dentistry. He must also perform to the satisfaction of the examiners a piece of special dental work demanding a high degree of skill and experience.

The examinations are held concurrently with the medical examinations.

The practical examinations in dentistry are conducted at the Newcastle-upon-Tyne Dental Hospital.

#### FEES.

The following fees are payable: Matriculation, £2; Examinations, First, Second, and Third M.B., B.S., each £5; Final M.B., B.S., £15; M.D. and M.S., each £5; B.Hy., D.P.H., and D.Psy., each £10 10s., and D.Hy. and D.Ch. each £20; First, Second, and Third L.D.S., each £3 10s., and Final L.D.S. £5; First, Second, and Third B.D.S., each £5, Final B.D.S. £8; and M.D.S. £5. For degrees and diplomas: M.B., B.S., B.Hy., and B.D.S., each £6 6s., plus the sum of 10s. if it is the initial degree taken in the university; M.S. and M.D.S., each £6 6s.; M.D., D.Ch., and D.Hy., each £10; D.P.H., D.Psy., and L.D.S., each £5.

Further information may be obtained from Professor Howden, Registrar, University of Durham College of Medicine, Newcastle-on-Tyne.

## UNIVERSITY OF LEEDS.

The degrees granted in the Medical Faculty of this university are Bachelor of Medicine, Bachelor of Surgery (M.B. and Ch.B.), and Bachelor of Dental Surgery (B.Ch.D.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), and Master of Dental Surgery (M.Ch.D.). It also gives diplomas in public health, in psychology, in dental surgery and in nursing.

Candidates for the M.B. must have attended courses of instruction approved by the university for not less than five years, two at least of such years having been passed in the university, at least one year being subsequent to the date of passing the first examination. They must also have matriculated by satisfying the examiners in:

- I. *Either* English Composition and English Literature, *or* English Composition and History.
- II. *Either* Mathematics *or* Latin.
- III. } Three other subjects not already taken under I and II above,
- IV. } chosen from the following list:
- V. }
 

|   |                                   |
|---|-----------------------------------|
| 1. English Literature.                            | 9. Mathematics.                   |
| 2. History.                                       | 10. Mechanics.                    |
| 3. Geography.                                     | 11. Physics.                      |
|   | 12. Chemistry.                    |
| 4. Greek.   | 13. General Experimental Science. |
| 5. Latin.   | 14. Natural History.              |
| 6. French.  | 15. Botany.                       |
| 7. German.  |                                   |
| 8. Some one other language approved by the Board. |                                   |

*Provided that* (a) candidates who take Mathematics under II above must include one of the subjects 4–8; (b) candidates who take Latin under II above must include one of the subjects 9–15.

Exemption from the examination may be granted to applicants holding certificates of having passed examinations of a standard deemed by the Matriculation Board to be at least equal to the Board's examination.

#### PROFESSIONAL EXAMINATIONS.

The examinations for the M.B., Ch.B. number three. The first deals with (1) physics and chemistry, (2) biology. In each subject laboratory work is included, but the two parts can be taken separately. For neither can the candidate present himself until after matriculation and a period of approved work in the respective subjects.

**The Second Examination.**—The Second Examination consists of: Part I, Organic Chemistry; Part II, Materia Medica, Practical Pharmacy, and Pharmacology; Part III, Anatomy and Physiology. Candidates will be allowed to pass any parts separately, but Part I must be passed before Parts II or III.

**The Final Examination.**—The Final Examination consists of: Part I, Pathology and Bacteriology; Part II, Medicine, Surgery, Obstetrics, Gynaecology, and Clinical Pathology; Part III, Forensic Medicine, Public Health, and Therapeutics. Part I may be taken at the end of the second clinical year, and Parts II and III may be taken at the end of the third clinical year but not before the completion of the fifth year of medical study. If taken separately Part II must be passed before Part III.

**M.D.**—A candidate for this degree must be a M.B., Ch.B. of the university of at least one year's standing. He presents a dissertation embodying the results of personal observation or original research, and, if this is approved, he may be required to write a short extempore essay on some topic connected with medicine, and may be examined orally on the dissertation or other work submitted.

**Ch.M.**—The candidate for this degree must have been admitted to the M.B., Ch.B. of the university not less than a year previously, and during that time must have held for at least six months a surgical appointment in a public institution affording full opportunity for the study of practical surgery. He must also have attended certain courses, including one on ophthalmology and one on bacteriology; he is then examined on the subject of surgery in all its branches.

#### FEES.

The matriculation fee is £2, and on readmission £1 10s. For each of the other examinations £6 (£7 for Ch.M.); and £3 on readmission. On conferment of the degree of Ch.M. £7 is payable, and £6 for the M.D. degree.

## UNIVERSITY OF LIVERPOOL.

This university, besides granting degrees in medicine (M.B. and M.D.) and in surgery (Ch.B., M.Ch.Orth., and Ch.M.), gives degrees in dental surgery (B.D.S. and M.D.S.), a degree in hygiene (M.H.), and degrees in veterinary science (B.V.Sc., M.V.Sc., and D.V.Sc.). Diplomas are awarded in dental surgery (L.D.S.), tropical medicine (D.T.M.), tropical hygiene (D.T.H.), public health (D.P.H.), veterinary hygiene (D.V.H.), and medical radiology and electrology (D.M.R.E.). The degree of Doctor of Philosophy (Ph.D.) may also be taken in the Faculty of Medicine.

## MATRICULATION.

The Matriculation Examination is governed by the Joint Matriculation Board, 315, Oxford Road, Manchester, which accepts, under certain conditions, the tests of several other bodies as its equivalent. Chemistry and physics are essential pre-registration subjects.

## PROFESSIONAL EXAMINATIONS.

Candidates for the M.B., Ch.B. degrees have three examinations to pass, the first including (1) chemistry, (2) physics, (3) biology (zoology and botany).

*Second M.B.*—This test covers (a) (1) anatomy, (2) physiology, including physiological chemistry and histology; and (b) (3) elementary bacteriology, (4) clinical chemistry, (5) general pathology. Candidates may present themselves in (a) and (b) separately.

*Final M.B.*—The subjects of the Final Examination are: (a) (1) special pathology and morbid anatomy, (2) forensic medicine and toxicology, (3) public health, (4) pharmacology and general therapeutics; (b) (5) obstetrics and diseases of women, (6) surgery—systematic, clinical, operative, and practical—including ophthalmology, (7) medicine—systematic and clinical—including therapeutics, mental diseases, and diseases of children. Candidates may take Parts (a) and (b) separately, but Part (b) may not be taken until five years of study have been completed.

*M.D. and Ch.M.*—Candidates for these degrees must have received the M.B. and Ch.B. at least two years previously. Students holding equivalent degrees of other approved universities may become candidates for the M.D. degree after two years' study in the university or clinical school of the university. The M.D. candidate submits for approval a thesis covering original work in some branch of medicine or some science directly relative to medicine, together with, if desired, copies of published work. The M.Ch. candidate undergoes an examination. Other information concerning the diplomas of this university and its medical school will be found on page 440.

## FELLOWSHIPS, SCHOLARSHIPS, AND EXHIBITIONS.

The university awards Fellowships annually to students of distinguished merit, as follows:

(1) John Rankin Fellowships in Anatomy; two, each of the value of £120, tenable for two years. (2) Ethel Boyce Fellowship in Gynaecology, value £100 and tenable for one year, open to fully qualified medical students of either sex. (3) John W. Garrett International Fellowship in Bacteriology, value £100 and tenable for one year. (4) Robert Gee Fellowship in Human Anatomy, value £100 and tenable for one year. (5) Holt Fellowships in Physiology and Pathology, two in number, value £150 each and tenable for one year. (6) Johnston Colonial Fellowship in Biochemistry, value £100 and tenable for one year. (7) Thelwall Thomas Fellowship in Surgical Pathology, value £150 and tenable for one year. (8) Lady Jones Fellowship in Orthopaedic Surgery, one, value £200, offered every two years.

There are, in addition, scholarships and exhibitions open to medical students.

## VICTORIA UNIVERSITY OF MANCHESTER.

This university grants the four ordinary degrees in medicine and surgery—M.B. and Ch.B. and M.D. and Ch.M.; a degree and diploma in dental surgery; a diploma in public health; a certificate in factory and in school hygiene; a diploma in psychological medicine; and a diploma in bacteriology. Candidates for degrees must pass the special Matriculation Examination prescribed by the Faculty of Medicine (or some equivalent examination accepted in lieu thereof; see the prospectus of the Joint Matriculation Board), and study at the university itself

for at least two years of the six years' curriculum, subsequent to the passing of the First M.B. Examination. The Matriculation Examination comprises (1) Latin, (2) mathematics, (3) the English language, its literature and history, (4) mechanics, (5) one subject at choice as approved by the Joint Board. It is held in July and September.

## PROFESSIONAL EXAMINATIONS.

*M.B., Ch.B.*—There are four examinations for this degree. They must be passed in proper order, and before admission to them the candidate must be duly certified as having attended in the subjects involved. The first M.B. is divided into Part 1, chemistry and physics; Part 2, biology—(a) botany, (b) zoology. The parts may be taken separately or together. At the second M.B. the candidate is examined in anatomy (including histology) and physiology; at the third, in pathology and pharmacology (including materia medica and practical pharmacy). The Final Examination is divided into two parts, which may be taken separately, and includes medicine (systematic and clinical), mental diseases, and diseases of children, surgery (systematic, clinical, and practical), obstetrics and gynaecology, preventive medicine, forensic medicine, and toxicology.

*M.D.*—A candidate for this degree must be a bachelor of medicine of at least one year's standing. He has a choice between presenting an original dissertation or undergoing a written (as well as practical and clinical) examination in medicine, and a written and practical examination in pathology, and one other subject selected by himself.

*Ch.M.*—A candidate must have held, since becoming Ch.B., and for not less than twelve months, a post in a public institution affording opportunity for the study of the branch of surgery in which examination is desired. The examination in Branch I comprises the general field of surgery; Branch II, obstetrics and gynaecology; Branch III, ophthalmology; Branch IV, otology, laryngology, and rhinology.

*B.Sc. and M.Sc.*—The ordinary degree of B.Sc. in the Schools of Anatomy and Physiology may be obtained by students in medicine who in their third year of study for the degree of M.B., Ch.B. complete the additional courses in these subjects prescribed for this degree. Candidates for the Honours degree of B.Sc. in Anatomy or Physiology who are students in medicine are required to attend courses in advanced anatomy and physiology for four terms after passing the Second Examination for the degrees of M.B., Ch.B. Graduates in science of this university, of not less than one year's standing from the date of their graduation as Bachelors, may proceed to the degree of M.Sc. by the presentation of an approved thesis on some subject coming within the scope of the Faculty of Science.

## FEES.

The following examination fees are payable: Matriculation, £2; on readmission, £1 10s. Each M.B. examination, £8 8s.; on readmission, £3 3s. M.D., including the conferring of the degree, £15 15s. Ch.M., £10 for the examination and £10 10s. for conferment of degree. Application for further information should be addressed to the Dean of the Medical School.

## UNIVERSITY OF SHEFFIELD.

The degrees of this university (M.B., Ch.B., M.D. and Ch.M., B.D.S., and M.D.S.), the diploma in public health, and the diploma of licentiate in dental surgery, are open to candidates of either sex. Candidates for a degree must have matriculated in the university or have passed such other examination as may be recognized for this purpose, and have passed the further examination in chemistry and physics.

## PROFESSIONAL EXAMINATIONS.

A candidate for the degrees of M.B., Ch.B. must produce certificates that he will have attained the age of 22 years by the day of graduation; that he has pursued the courses of study required by the university regulations during not less than five years subsequent to the date of his matriculation or exemption from matriculation, and the passing of the further examination in chemistry and physics, three of such years at least having been passed in

the university, one at least being subsequent to the passing of the First Examination. The following examinations must be passed in due order.

**First Examination.**—The subjects are chemistry, physics, and biology. Candidates who have passed the Intermediate Examination of the Faculty of Pure Science in any or all of the subjects of the First M.B. Examination will, on payment of the fee for the latter examination, be deemed to have passed it when they have passed in such subjects as they did not take for the Intermediate B.Sc. Examination. Candidates on presenting themselves for this examination are required to furnish certificates of having attended for not less than one year approved courses of instruction, after matriculation, and the passing of the further examination in physics and chemistry, in (i) chemistry, inorganic and organic; (ii) physics; (iii) biology.

**Second Examination.**—The subjects are anatomy and physiology. The candidate must have completed the second year of professional study, must have passed the First Examination, and must have attended (1) courses on anatomy, including lectures and practical anatomy, during one year; (2) courses on physiology, including lectures and practical histology, during one year.

**Third Examination.**—The subjects are pathology and pharmacology, anatomy, and physiology. Candidates must have completed the fourth winter of medical study and the requisite courses in these subjects, including *post-mortem* clerkship for three months.

**Final Examination.**—The subjects are—Part I, forensic medicine and public health; Part II, medicine (including mental diseases and diseases of children), surgery, obstetrics (including gynaecology). Candidates for Part I must have completed Michaelmas term of the fifth year of study; candidates for Part II must have completed the fifth year of study.

**M.D.**—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, must present a thesis embodying observations in some subject approved by the Professor of Medicine, and must pass an examination in the principles and practice of medicine.

**Ch.M.**—Candidates for the degree of Master of Surgery must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, and must, since taking the degrees of M.B., Ch.B., have held for not less than six months a surgical appointment in a public hospital or other public institution affording full opportunity for the study of practical surgery. The subjects of examination are systematic, clinical, and operative surgery, surgical anatomy, surgical pathology, and bacteriology.

Other information concerning this university will be found in the section devoted to Provincial Medical Schools.

#### UNIVERSITY OF WALES.

The Charter and statutes of the University of Wales provide *inter alia* for a Faculty of Medicine and for the granting of the following degrees: Bachelor in Medicine (M.B.), Bachelor in Surgery (B.Ch.), Master in Surgery (M.Ch.), and Doctor in Medicine (M.D.).

A candidate for the M.B., B.Ch. is required to pursue a course of study of not less than six academic years subsequent to matriculation in the university, and of these years at least three must have been passed in one of the constituent colleges of the university. These are the University College of Wales, Aberystwyth; University College of North Wales, Bangor; University College of South Wales and Monmouthshire, Cardiff; and University College, Swansea. He must also hold an arts or science degree of the University of Wales, or of some other university approved for this purpose. Certain of the courses of study pursued for a B.Sc. or B.A. degree may be counted as courses required for the degrees in the Medical Faculty.

The courses for the M.B., B.Ch. are divided into two sections, of which the first includes the preliminary subjects—physics, chemistry, botany, zoology; and the ancillary subjects—organic chemistry, human anatomy, and physiology. Study of the preliminary subjects and of organic chemistry must extend over at least one academic year; study of physiology and anatomy must extend over at least

two academic years; the first section of the course must occupy not less than three years. The second section includes courses in pathology, bacteriology, pharmacology, hygiene and forensic medicine, medicine, surgery, and obstetrics and gynaecology, and cannot be commenced, except in the case of pharmacology, until the examinations relating to the preliminary and ancillary courses have been passed. Examinations in all the subjects are held in June of each year.

The university also offers courses of study in public health and in tuberculosis. Candidates for the Diploma in Public Health (D.P.H.) and for the Tuberculous Diseases Diploma (T.D.D.) must possess a medical qualification registrable for practice in Great Britain and Ireland, and must have completed courses of study as prescribed by the regulations either at the Welsh National School of Medicine, Cardiff, or at another institution approved by the university.

#### WELSH NATIONAL SCHOOL OF MEDICINE.

Students can complete the whole of their curriculum in the Welsh National School of Medicine, which is an integral part of the University College of South Wales and Monmouthshire, and qualify for the degrees of M.B., Ch.B. in the university.

Further information may be obtained from the Registrar, the University Registry, Cathays Park, Cardiff.

## English Medical Corporations.

THERE are in England three medical corporations which grant licences to practise—the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. The first two combine for certain purposes to form what is known as the Conjoint Board in England. Details concerning this body, its component Colleges, and the third licensing body here follow.

#### THE CONJOINT BOARD.

THIS body—the Examining Board in England—deals with the qualifications of all candidates for the Licence of the Royal College of Physicians of London and for the Membership of the Royal College of Surgeons of England. It prescribes for them certain periods of study, and recommends those who pass the required examinations for the Licence and for the diploma of Member respectively. The successful candidate is then entitled to register as L.R.C.P.Lond., M.R.C.S.Eng. It performs the same task in connexion with diplomas in public health, tropical diseases, ophthalmic medicine, medicine, and laryngology and by the two Colleges in question. Under the new regulations, which apply to all students who have not passed the required preliminary tests of general education before January 1st, 1923, every candidate for the M.R.C.S. and L.R.C.P. must (1) complete five years of professional study after passing a recognized preliminary examination and a recognized pre-medical examination in chemistry and physics; (2) comply with the regulations, which may be had from the Secretary, Examination Hall, Queen Square, Bloomsbury, London, W.C.1; and (3) pass the two professional examinations of which particulars appear below. The old regulations for the Conjoint diploma, of which an account was given in the Educational Number for 1922, still apply to students who passed their preliminary examination in general education before January 1st, 1923.

#### NEW REGULATIONS FOR THE CONJOINT DIPLOMA.

The following is an outline of the regulations applicable to candidates for the L.R.C.P.Lond. and M.R.C.S.Eng. who passed the required Preliminary Examination in general education on or after January 1st, 1923. The full regulations and synopses and forms of certificate may be obtained from the Secretary.

#### PRE-MEDICAL EXAMINATION.

Students are required to pass a pre-Medical Examination in Chemistry and Physics conducted by the Conjoint Examining Board before commencing the five years' curriculum of professional study.

or some other examination recognized by the Board—namely, the examination in Chemistry and Physics for the degree in Medicine of any university; Board, the Higher School Certificates of Universities and the Oxford and Cambridge Board, the Higher Certificates of London, Bristol, Durham Universities, the Joint Matriculation Board of the Northern Universities, and the Central Welsh Board Higher Certificate.

A candidate must enter for Chemistry and Physics together and he will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other subject. He will be admitted to the examination on producing evidence of having passed the required Preliminary Examination in General Education and of having received instruction during 180 hours in Chemistry and 120 hours in Physics to the satisfaction of his teachers. These courses may be commenced or attended before the required Preliminary Examination in General Education is passed.

The examination is partly written, partly oral, and partly practical. A candidate rejected in one or both subjects of the examination will not be admitted to re-examination until after the lapse of a period of not less than three months, and he must produce evidence of further instruction in the subject or subjects of failure.

#### PROFESSIONAL EXAMINATIONS.

There are two Professional Examinations, called the First and Final Examinations. The courses of study for the First Examination may be commenced before the Pre-Medical Examination in Chemistry and Physics or some equivalent examination has been passed provided three terms of study of anatomy and physiology are completed after passing such examination.

**First Professional Examination.**—The subjects of this are: Section I, (a) Anatomy, including Histology and Embryology; (b) Physiology, including Biochemistry. Section II, Pharmacology, Practical Pharmacy, and Materia Medica. A candidate must have attended at a recognized Medical School courses of instruction in Anatomy, including Embryology, during five terms, during which he must have dissected the whole body, courses of instruction in Physiology, including General Biology, Biochemistry, and Biophysics during five terms, courses of instruction in Pharmacology, Practical Pharmacy, and Materia Medica. A candidate may present himself for the two sections together or separately, but he must take parts (a) and (b) of Section I together until he has passed in one or both parts, but a candidate will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part. Section II of the examination may be passed at any time before the candidate enters for the Final Professional Examination. A candidate who produces satisfactory evidence of having passed an examination in the subjects of Section I or of either part of Section I and of Section II in the examination for the degree in Medicine conducted at a university recognized by the Board will be exempted from further examination in such subject or subjects.

**Final Professional Examination.**—The subjects of this are: Section I, (a) Pathology, including Morbid Anatomy, Morbid Histology, and Clinical Pathology; (b) Bacteriology. Section II, Part I, Medicine, including Medical Anatomy, Forensic Medicine, and Public Health; Part II, Surgery, including Surgical Anatomy and the use of Surgical Appliances; Part III, Midwifery and Gynaecology. The examination is partly written, partly practical, partly clinical, and partly oral. A candidate may take Sections I and II and the three parts of Section II of the Final Examination separately or may take the whole examination together. He will be required to produce the certificates required by the regulations before being admitted to the respective parts of the examination. A candidate who produces evidence of having passed an examination for a degree in Medicine in the subjects of Pathology and Bacteriology at a university recognized by the Board is exempted from Section I.

#### FEES.

The fee for the *Pre-Medical Examination* is three guineas, for re-examination in Chemistry two guineas, and for re-examination in Physics one guinea. The fee for the *First Professional Examination* is ten guineas, for re-examination after rejection in Section I six guineas, for re-examination after rejection in either part of Section I three guineas, for re-examination after rejection in Section II three guineas. The fee for admission to Section I of the *Final Professional Examination* is four guineas, for admission to Section II, Part I, ten guineas, Part II ten guineas, Part III six guineas; and the re-examination fees are respectively three guineas, six guineas, and four guineas.

#### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THIS College has three grades—its Licentiates, its Members, and its Fellows. The Licence is now only issued through the Conjoint Board. The Membership is only granted to those who have passed the final examinations for the Licence, or those who are registered practitioners and graduates of a recognized university; in any case they must be persons over 23 years of age. Candidates are examined in pathology and the practice of physic, partly in writing and partly viva voce; they are also examined in Latin, Greek, French, and German. The languages are not compulsory, but credit is given to those who show a knowledge of them. The fee for the Membership is £42, or in the case of a Licentiate £21. There is a fee of £6 6s., payable

before entrance to the examination, which in the case of successful candidates is reckoned as part of the Membership fee. The body of Fellows is maintained by election from among the Members.

#### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THIS College has two grades—Members and Fellows. The Members are admitted as stated in the section dealing with the Conjoint Board. The Fellowship is granted after examination to persons at least 25 years of age who have been engaged in professional studies for six years. There are two examinations for the Fellowship—the first in anatomy and physiology, which may be passed after the third winter session; the second, chiefly directed to surgery, which may be passed after six years of professional study. Candidates must pass the Final Examination of the Examining Board in England and be admitted Members of the College before admission to the Second Examination for the Fellowship, except in the case of graduates in medicine and surgery of not less than four years' standing of universities recognized by the College for the purpose, who are required to attend for one year the surgical practice of a general hospital recognized by the College after obtaining their degrees.

**Fees.**—At first examination, £8 8s.; for re-examination, £5 5s. At second examination, £12 12s. Diploma fee for non-members, £10 10s.

#### SOCIETY OF APOTHECARIES OF LONDON.

THIS body confers a registrable diploma in medicine, surgery, and midwifery, now known as the L.M.S.S.A. (Licentiate in Medicine and Surgery of the Society of Apothecaries), on those successful at the following examinations:

**Primary Examination.**—This is divided into two parts, of which Part I includes chemistry, chemical physics, practical chemistry, biology, and pharmacy. Part II includes anatomy, physiology, and histology, and cannot be passed before the completion of twelve months' practical anatomy with demonstrations. Candidates will be excused any or all the subjects of the primary examination on producing evidence that they have passed equivalent examinations before an examining body recognized by the Society. Candidates referred in anatomy will be required to produce evidence of further work in the dissecting room before being admitted to re-examination.

**Final Examination.**—This is divided into three parts. Part I includes clinical surgery, the principles and practice of surgery, surgical pathology, operative manipulation, surgical anatomy, instruments and appliances. Part II includes clinical medicine: (a) the principles and practice of medicine (including therapeutics, pharmacology, and prescriptions), pathology, and morbid histology; (b) forensic medicine, hygiene, theory and practice of vaccination, and mental diseases. Part III includes midwifery, gynaecology, and diseases of newborn children, obstetric instruments and appliances.

The fee for the primary examination is £5 5s.; for the final, £15 15s. The regulations and synopses relating to the several examinations, and other information, may be obtained from the Secretary, Court of Examiners, Apothecaries' Hall, Blackfriars, E.C.4.

## The Scottish Universities.

THERE are in Scotland four universities, each possessing a faculty of medicine, and having the right to confer degrees which admit the holder to the *Medical Register*. In essential points the regulations in their medical faculties for undergraduates are much alike, so that a general account can be given of all of them together.

The universities are those of Edinburgh, Glasgow, Aberdeen, and St. Andrews. The provision each of the cities in which these universities are situated makes for the education of medical students will be found in the section on Medical Schools in Scotland: here it need merely be said that degrees in medicine from Scotland as a whole have always enjoyed a high reputation.

The degrees granted in medicine and surgery to candidates of either sex are four in number—Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.). The two former are not obtainable one apart from the other. Besides these degrees a diploma in tropical medicine and hygiene is obtainable from the University of Edinburgh, as also diplomas in psychiatry, public health, and radiology. As for public health, registrable degrees in this subject are granted by the universities of Edinburgh and Glasgow, while diplomas in public health may be obtained from the universities of St. Andrews and Aberdeen.

The conditions for admission of graduating students of medicine are the same as those in the Faculties of Arts or Science (for degrees in pure science).

As from January 1st, 1925, prospective medical students are also required to pass a pre-registration examination in chemistry and physics.

#### PROFESSIONAL EDUCATION.

The regulations comply in all respects with the requirements and recommendations of the General Medical Council, and, in addition, necessitate definite study for stated periods of diseases of children, of the larynx, ear, and nose, of the skin, of ophthalmology, and of mental diseases. In respect of the various courses certificates must be obtained showing that the student has not only attended regularly, but has duly performed the work of the class. Out of the necessary five years of medical study, not less than two must be spent at the university whose degrees the student hopes to obtain, and the balance at any place officially recognized for such purpose. In each academic year there are two sessions—one lasting from the beginning of October to the middle of March, and the other from the middle of April to the beginning of July.

#### PROFESSIONAL EXAMINATIONS.

The distinctive feature of the Scottish curriculum is that, though nominally there are only four examinations, each of these may be, and habitually is, split up by the student into sections. Hence, a student may complete some stage of his career during the course of nearly every session. Thus, by the end of the first winter session the student may pass in zoology and chemistry. At the end of the first summer session he can finish with botany and physics, and with anatomy and physiology at the end of the second. Pathology and materia medica he will pass at the end of the third year, and so on, until the final examination in midwifery, surgery, and medicine, and the corresponding clinical subjects, at the end of the fifth year of study. At each examination the candidate may pass "with distinction," and a record is kept of the merit displayed, so that, when the time comes for the candidate to graduate, one who has done well throughout can be declared as graduating with first or second class honours. A further point in the system is that the student's own teachers commonly take some part in his examination.

Of the four examinations, the first deals with physics, botany, zoology, and chemistry; the second with anatomy and physiology; the third with materia medica and pathology; the fourth with medicine and surgery (clinical and systematic), midwifery, clinical midwifery, and clinical gynaecology, and forensic medicine and public health. The first three examinations are held three times a year; the final twice a year.

Exemption from the first professional examination can be obtained by candidates who have passed an arts or science degree examination in its subjects at any recognized university. When a candidate presents himself for an examination in several of its parts, but is not successful in all of them, he is credited at the next examination with those subjects in which he has already been approved.

#### THE HIGHER DEGREES.

It is open to those who are already M.B., Ch.B. to proceed either to the M.D. or the Ch.M. A candidate for the former must have been engaged for not less than one year in work in the medical wards of a hospital, or in scientific research in a recognized laboratory, or in the

Naval or Military Medical Services, or have been at least two years in general practice, and he must be 24 years of age. He has to write a thesis on any subject not exclusively surgical, and is examined in clinical medicine and in some one or other of its special departments. The regulations for candidates for the Ch.M. are of a corresponding character, a period of surgical work in a hospital or elsewhere being substituted for medical work, and the thesis being on a surgical rather than a medical subject. He is examined in surgical anatomy, clinical surgery, operative surgery, and in some of the special departments of surgery.

#### FEES.

It is estimated that the class, examination, and other fees for the M.B., Ch.B. come altogether to about £247, the separate examination fees included in this calculation being as follows:

|                        |     |     |     |     |    |    |    |
|------------------------|-----|-----|-----|-----|----|----|----|
| First Professional ..  | ... | ... | ... | ... | £  | s. | d. |
| Second Professional... | ... | ... | ... | ... | 9  | 9  | 0  |
| Third Professional ..  | ... | ... | ... | ... | 7  | 7  | 0  |
| Final ..               | ... | ... | ... | ... | 6  | 6  | 0  |
|                        | ... | ... | ... | ... | 11 | 11 | 0  |

Re-entry in any subject in which the candidate has failed entails a fresh payment of £1 ls. Candidates for the M.D. and Ch.M. pay £21, and on re-entry £5 5s.

More detailed information with regard to the University of Edinburgh can be obtained from the *Medical Programme*, price 6d., which is published by Mr. Thin, 55, South Bridge, Edinburgh, or on application to the Dean of the Faculty of Medicine. Similar information about Glasgow should be sought from the Assistant Clerk, Matriculation Office, Glasgow. With regard to Aberdeen, application may be made to the Secretary of the Medical Faculty, Marischal College. In respect of St. Andrews information can be obtained either from the Secretary of the University, or, alternatively, the Secretary of the United College, St. Andrews, or the Secretary of University College, Dundee, these being the two constituent colleges of the University of St. Andrews.

Finally, it should be mentioned that in connexion with all the Scottish universities there are valuable bursaries and scholarships, some information as to which will be found in the article on Medical Schools.

#### THE CARNEGIE TRUST.

The following is a summary of the regulations made by the Carnegie Trust for the universities of Scotland for assistance in the payment of class fees in the universities and extra-mural colleges of Scotland.

Applicants must be over 16 years of age; they must be of Scottish birth or extraction, or have attended for two years, after the age of 14, at a school or institution under inspection of the Scottish Education Department. Applicants so qualified who have been pupils of schools under the Scottish Education Department will be eligible for assistance in the payment of class fees if they have obtained the leaving certificate of the Department, provided that it bears evidence of such preliminary education as is required by the universities for their graduating curricula, or that it has been supplemented by such passes either in the Scottish Universities Preliminary or other examination as will satisfy the above requirement of the universities. Where applicants have not been pupils of schools under the Scottish Education Department, or where other good ground for not having obtained the leaving certificate can be shown, the Executive Committee has power to accept instead what it deems equivalent evidence of attainments.

Applicants in the Faculties of Arts and Science must have had their course of study for each academic year approved by the University Adviser of Studies, and they must have passed the graduation examinations belonging to the previous stage of their curriculum before becoming eligible for assistance in the payment of fees of classes belonging to a further stage. Beneficiaries must submit to the Executive Committee at the end of each session particulars as to their attendance and work, any distinctions gained, and any graduation examinations passed.

The annual allowance towards payment of class fees offered to beneficiaries by the Trust in the Faculty of Medicine is £19 for four years, in all £76. Any unexpended part of a grant will be carried forward to the succeeding year. In combinations of Faculties the allowances available for beneficiaries are: Arts and Medicine—two Arts grants of £8 and four Medicine grants of £19, in all £92; Science and Medicine—two Science grants of £17 and four Medicine grants of £19, in all £110.

Applicants, in writing for application forms, must name the university and faculty in which they intend to study, and state whether they have previously obtained the benefits of the Trust. Applications must be lodged not later than October 25th for the winter session, or May 10th for the summer session. Payments are made by means of fee coupons, and fees already paid are not refunded.

## The Scottish Corporations.

THERE are three medical corporations in Scotland—the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Their licences can be separately obtained only by persons who are already in possession of a recognized qualification—in surgery in the case of the College of Physicians, and in medicine in the case of the College of Surgeons and the Faculty of Physicians and Surgeons of Glasgow. All others must submit to the examinations held by the Conjoint Board which the three corporations have combined to form. Details concerning this Board and its component colleges follow. The conditions on which their higher qualifications are granted will be found set forth separately in connexion with each corporation.

### THE CONJOINT BOARD IN SCOTLAND.

THIS body has charge of all questions connected with candidates for the Conjoint Licences of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Those finally approved by it are entitled to registration and to the initials denoting the Licences of the three bodies concerned—namely, L.R.C.P. Edin., L.R.C.S. Edin., and L.R.F.P.S. Glas. The Board requires all candidates to comply with the regulations of the General Medical Council. It has an arts examination of its own, but is prepared to accept in its place any of the other educational tests approved by the General Medical Council. All candidates must obtain registration with the General Medical Council.

#### *Professional Curriculum for Candidates registered as Medical Students prior to January 1st, 1923.*

SUBSEQUENT to registration as a medical student the candidate must pass not less than five years in medical study, each comprising a winter and a summer session. The Board does not insist that candidates shall pursue their study at any particular place, and is prepared to accept certificates of having attended the necessary courses from any recognized medical school.

ITs examinations are four in number, each of them being held four times every year, and these will fall to be held twice in Edinburgh and twice in Glasgow during the next period; it is open to candidates to present themselves for examination at either place. The first examination deals with physics, chemistry, and elementary biology; the second with anatomy and physiology, including histology; the third with pathology and materia medica, including pharmacy; and the final with (1) medicine, including therapeutics, medical anatomy, and clinical medicine; (2) surgery, including surgical anatomy, clinical surgery, and diseases and injuries of the eyes; (3) midwifery and diseases of women and of newborn children, including clinical gynaecology and practical midwifery; and, if it has not been passed previously, (4) medical jurisprudence and hygiene. Candidates will also be examined on diseases of children, diseases of the ear and throat, insanity, vaccination, etc.

THESE examinations must be passed in due order, and before admission to any of them the candidate must supply certificates showing that he has completed the due periods of study of their subjects. He can present himself in any single subject of the first three examinations. As regards the final examination, a candidate can present himself in medical jurisprudence and hygiene at any time after completion of the third examination and of his study of these subjects; but in medicine, surgery, and midwifery he cannot present himself until the completion of five years' study, and he must take them all simultaneously. A candidate who takes up several subjects of an examination or the whole of the subjects at one time, but fails in some of them, is credited at the next examination with those subjects in which he has been approved.

All candidates for the Final Examination must complete

the pass in the three portions (medicine, surgery, and midwifery) within a period of nineteen months.

PART or entire exemption from the first three examinations may be granted to those who have already passed before other bodies examinations deemed by the Board equivalent to its own, but all candidates for the Conjoint licence must sit for the Final Examination, and at no examination can a candidate present himself within three months of his rejection by some other licensing body.

#### *Professional Curriculum for Candidates registered as Medical Students after January 1st, 1923.*

THE curriculum has been extended to meet the recommendations of the General Medical Council. Candidates, when applying for copies of regulations, should state date of medical registration.

#### FEES.

IT is estimated that the total cost of lectures and fees for the Conjoint licence is about £152. The separate examination fees are as follows: First, Second, and Third Professional, £5 each; Final £15. On re-entry for any of the first three examinations £3, and on re-entry for the Final, £5. If the re-entry is only in one or two subjects of the First, Second, or Third Examinations the fees are smaller.

INFORMATION concerning this Board should be sought either from Mr. D. L. Eadie, 49, Lauriston Place, Edinburgh, or from Mr. Walter Hurst, Faculty Hall, 242, St. Vincent Street, Glasgow.

### ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

THIS College has three grades—Licentiatehip, Membership, and Fellowship—all of which are open to men and women. The regulations applying to candidates for the Licentiatehip have already been generally indicated. If desirous of receiving it apart from those of the other two corporations they must be holders of a surgical qualification recognized by the College, and must pass an examination corresponding to the medical part of the Final Examination of the Conjoint Board, and conditioned in the same way, and also an examination in materia medica. The fee for examination is 15 guineas, a special examination being obtainable on due cause being shown, and on payment of 5 guineas extra. Ordinary examinations take place monthly on the first Wednesday and Thursday, except in September and October. Candidates for the Membership must be either Licentiates of a British or Irish College of Physicians, or alternatively graduates of medicine of a university, approved by the Council, and in either case not less than 24 years of age. Candidates are examined in medicine and therapeutics, also on one or more departments of medicine specially professed, and approved by the Council, in which a high standard of proficiency will be expected. The fee to be paid by a candidate for the Membership is £36 15s. The examination is held quarterly, and application for admission to it must be made a month previous to its date. For the Fellowship the candidate must have been a Member of the College for at least three years, and, if accepted, pays fees, including £25 stamp duty, amounting altogether to £64 18s. Further details can be obtained on application to the Secretary of the College.

### ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THIS College has two grades—its Licence and its Fellowship. Licentiates may be of either sex, and for the Fellowship women are eligible also.

#### *Licence.*

AS an original qualification the Licence is only granted after fulfilment of the regulations of the Conjoint Board, but as an additional qualification it can be obtained by those already possessed of a registrable or equivalent qualification in medicine. In this case the candidate has to pass a written, oral, and clinical examination in surgery and surgical anatomy, and may be asked to operate on the dead body.

THE fee is £15 15s., of which £10 10s. is returned to unsuccessful candidates. On due cause being shown, a special examination may be granted, the fee being £20, of which £10 is returned to a candidate if he is not approved.

*Fellowship.*

Candidates for the Fellowship must be not less than 25 years of age, and have been in the practice or study of their profession subsequent to registration for at least two years, and must hold either a surgical degree from a university recognized for that purpose by the College, or a registrable diploma obtained as the result of an examination which includes surgery as well as medicine and midwifery. Candidates are examined in (a) the principles and practice of surgery, including surgical anatomy, (b) clinical surgery, and (c) one optional subject, which they may choose from among the following: surgical pathology and operative surgery, ophthalmology, laryngology, otology and rhinology, gynaecology, obstetric surgery, anatomy, and dental surgery and pathology. The examination is written, oral, and clinical or practical. A candidate who desires to be examined must give one month's notice, his application for admission being supported by two Fellows of the College, one of whom must be resident in Edinburgh, or, in default, by testimonials specially obtained for the purpose. Candidates are not allowed to appear more than three times at the examinations.

Licentiates of the College pay £35, and others £45. For further information application should be made to the Clerk of the College, Mr. D. L. Eadie, 49, Lauriston Place, Edinburgh.

### ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

THIS body possesses two classes—Licentiates and Fellows. The regulations applying to the former correspond with those respecting candidates for the Licence of the Royal College of Surgeons of Edinburgh. Candidates for the single Licence are examined in surgery (including clinical surgery and surgical anatomy). The fee is £15 15s. and examinations are held quarterly. Candidates for the Fellowship must be qualified medical men of not less than two years' standing and 24 years of age. Candidates approved at this examination are then eligible for election as Fellows. The Faculty can also elect four Fellows annually without previously submitting them to examination, provided they "have highly distinguished themselves in medical science or practice." They must be of not less than ten years' standing and 40 years of age.

The fee for the Fellowship is £50. Further information can be obtained from Mr. Walter Hurst, Faculty Hall, 242, St. Vincent Street, Glasgow.

## Irish Universities and Corporations.

### MEDICAL REGISTRATION IN THE IRISH FREE STATE.

A YEAR ago the Government of the Irish Free State announced that it had decided to establish a separate *Medical Register*. In February, 1926, an Act was passed by the Free State empowering the Executive Council of the State to continue existing arrangements, and they are now being continued from month to month. The President of the General Medical Council stated at its last meeting (June 1st, 1926) that communications had been received by the Secretary of State for Dominion Affairs from the Governor-General of the Free State intimating that the question of a permanent arrangement of the matter is engaging the attention of the Free State Government, and that it is hoped shortly to have a conference with the British Government for discussing a draft bill. It seems fairly certain that some arrangement will be reached under which students of medicine in the Free State and future graduates and diplomats of its universities and corporations will be able to register on the British *Medical Register*, and that therefore their choice of a place in which to practise will not be limited.

### THE IRISH UNIVERSITIES.

THERE are three universities in Ireland, each with a medical faculty. These are, in the Irish Free State, the University of Dublin (usually known as Trinity College, Dublin), and the National University of Ireland; and, in Northern Ireland, the Queen's University of Belfast.

### UNIVERSITY OF DUBLIN: TRINITY COLLEGE.

THIS university grants two degrees in medicine (M.B. and M.D.); two in surgery (B.Ch. and M.Ch.), two in midwifery (B.A.O. and M.A.O.), and a post-graduate diploma in public health. It also grants post-graduate diplomas in gynaecology and obstetrics, for which nine months' study is required, and in psychological medicine, for which twelve months' study is required. The degrees are granted to those who, having passed the Professional Examination, have also graduated in arts.

#### PROFESSIONAL EXAMINATIONS.

A candidate for the Final Examination for the M.B., B.Ch., and B.A.O. degrees must be a matriculated student of at least five years' standing. The examinations which students must pass are the Preliminary Scientific, the Intermediate Medical, and the Final. Before admission to any of these examinations students must have completed the courses of study in the subjects involved.

*Preliminary Scientific.*—This covers (a) chemistry, (b) physics, (c) botany and zoology; the three divisions may be taken together or at different times.

*Intermediate Medical.*—This is divided into two parts: (a) anatomy, physiology, organic chemistry, and histology; (b) applied anatomy and applied physiology. The two parts may be taken separately or together.

*Final Examination.*—Part I: Hygiene and medical jurisprudence, pathology and bacteriology, materia medica, and therapeutics. Part II: (a) Midwifery and gynaecology; (b) medicine and mental diseases; (c) surgery in all branches, including clinical ophthalmology. The three sections of Part II may be taken separately or together. In either case the full curriculum must have been completed, and the Final Examination cannot be completed before the end of the fifth year.

*M.D.*—The candidate must have passed all the qualifying examinations in medicine, surgery, and midwifery, and have taken, or have been qualified to take, the degree of B.A. three years previously. He must send in a thesis for approval. Subsequently the Regius Professor of Physic and an assessor will discuss with him questions connected with the thesis, and may also examine him viva voce on other medical subjects of a more general nature.

*M.Ch.*—The candidate must be a B.Ch. of not less than three years' standing, and have been engaged in practice for two years.

*M.A.O.*—The candidate must be a B.A.O. of not less than two years' standing and must produce satisfactory evidence of having been engaged for two years in obstetric science. The examination is specially directed to obstetrics and practical gynaecology.

Further information regarding courses of instruction, etc., may be obtained from the Registrar of the School of Physic, Trinity College, Dublin.

### QUEEN'S UNIVERSITY, BELFAST.

THE degrees granted by the Medical Faculty of this university are as follows: Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), Master of Obstetrics (M.A.O.). The university also confers a Diploma in Public Health. The first three degrees mentioned serve as a qualification for admission to the *Medical Register*, and are not granted separately. In addition to matriculating and passing his professional examinations, a candidate for these degrees must have passed three of the regulation five years as a student at the Belfast School of Medicine. Degrees in dental surgery (B.D.S. and M.D.S.) are conferred by the university, and also a diploma in dental surgery (L.D.S.).

#### PROFESSIONAL EXAMINATIONS.

The examinations for the M.B., B.Ch., B.A.O. are four in number. The first deals with: (1) inorganic, organic, and practical chemistry, (2) experimental and practical physics, (3) botany and practical botany, (4) zoology and practical zoology. It is divided into two parts, of which botany and zoology form one. The Second Examination covers anatomy and physiology, and may be taken at the

# IRISH UNIVERSITIES AND CORPORATIONS.

end of the second year of the student's career. The Third Examination includes: (1) pathology, (2) materia medica, pharmacology, and therapeutics, (3) medical jurisprudence, and (4) hygiene. To be valid a certificate in regard to the study of the subjects of this examination must show that the work has been done after the Second Examination has been passed.

The Final Examination includes: (1) medicine, (2) surgery, (3) midwifery, (4) ophthalmology and otology. The student may pass in all subjects at once at the end of his fifth year, or he may divide the examination into two parts—namely, (1) systematic, (2) clinical, practical, and oral. The first part may be taken at the end of the fourth year, but for the second part the candidate may not present himself until the end of his fifth year, but students invariably take both parts at the end of their course. No certificate in regard to the study of the subjects of this examination will be valid unless the work was done subsequent to passing in all the subjects of the Second Examination.

**THE HIGHER DEGREES.**  
Candidates for the degree of Doctor of Medicine must be graduates in medicine of at least three years' standing, unless they hold also a degree of the university in arts or science, in which case a standing of two academic years will suffice. Moreover, candidates must be able to show that the interval has been passed in the pursuit of such courses of study or practical work as may be prescribed. The degree may be conferred either (a) after a formal examination, or (b) in recognition of the merits of a thesis or of some piece of original study or research carried out by the candidate, followed by an oral or other examination in its subject. When an ordinary examination is imposed it will include (1) two written papers on the principles and practice of medicine, (2) a commentary on a selected clinical case, (3) a clinical and viva voce examination, and (4) a written paper and clinical or practical and viva voce examination on a subject chosen from the following list: (a) human anatomy, including embryology; (b) physiology, (c) pathology, (d) pharmacology and therapeutics, (e) sanitary science and public health, (f) forensic medicine and toxicology, (g) mental diseases. The regulations for the degrees of M.Ch. and M.A.O. are of the same general nature.

**NATIONAL UNIVERSITY OF IRELAND.**  
The National University of Ireland carries on most of its educational work through three constituent colleges—one in Dublin, one in Cork, and one in Galway. Each of these provides a full medical curriculum, and all candidates for the medical degrees of the university must pass three of their five years of study at one or other of them. These years do not count except after matriculation or recognition as a student of the Medical Faculty obtained in some other fashion. The candidates at each constituent college are examined by the university, and a common standard of education is secured by all courses of instruction and the regulations concerning report thereon approved by the Senate, after considering report thereon from the Board of Studies of the university. In addition to the ordinary degrees in medicine and surgery, the university grants those of Bachelor and Master of Public Health, and Bachelor and Master in Dental Surgery, as well as Diplomas in Public Health, in Mental Diseases, and in Tropical Medicine.  
Application for other information may be made to the Registrar, National University of Ireland, Dublin.

## THE IRISH CORPORATIONS.

There are, in the Irish Free State, three licensing bodies other than the Medical Faculties of the universities; and in Dublin, just as in London, there is a Royal College of Physicians of Ireland, a Royal College of Surgeons in Ireland, and an Apothecaries' Hall. In Dublin, as in London and in Edinburgh, the two Colleges have formed an examining Conjoint Board, which is responsible for the recommendation of candidates to the two bodies for their

respective licences. The Apothecaries' Hall of Ireland, like the Apothecaries' Society of London, gives its licence separately.

## THE CONJOINT BOARD IN IRELAND.

This body requires of candidates the passage either of its own preliminary examination in the subjects of general education or proof that the candidate has passed one of the tests accepted by the General Medical Council as well as passing in the Pre-Registration Examinations in Chemistry and Physics and Biology.

There are three professional examinations, the first of which cannot be passed earlier than the end of the second winter session, nor the final before the conclusion of full five years of medical study. Before being admitted to any of them the candidate must show that he has studied the different subjects in practice and theory for the requisite periods, certificates to this effect being accepted from the authorities of most of the recognized medical schools at home and abroad. The first examination deals with (a) anatomy, and (b) physiology and histology. The second examination deals with (a) pathology, (b) materia medica, pharmacy, and therapeutics and ophthalmology, and may be taken separately.

**Final Examination.**—This is divided into three divisions, which cannot be completed until at least five years have passed in medical studies other than those for the Pre-Registration Examinations, and five years at least since the beginning of the curriculum. The divisions are: (a) medicine, including fevers, mental diseases, and diseases of children; (b) surgery, including operative surgery; (c) midwifery, including diseases of women and newborn children, and the theory and practice of vaccination.  
Fees.—Preliminary Examination, £2 2s. Re-examination, £2 2s. Pre-Registration Examination, £3 3s. Re-examination in Chemistry, £2 2s.; in Physics, £1 1s. First Professional Examination, £25 5s.; Second, £15 15s.; Final, £6 6s. Re-examination fee is £2 2s. for each division.

**Diploma in Psychological Medicine.**  
There are two examinations in connexion with this diploma: Part I consists of (a) anatomy and physiology of the nervous system, (b) psychology. Part II—(a) neurology, including clinical and pathological neurology; (b) psychological medicine, including its legal relationships.

Fees.—£3 3s. for each part.  
Further information can be obtained from Mr. Alfred Miller, Secretary of the Committee of Management, Royal College of Surgeons, St. Stephen's Green, Dublin.

## ROYAL COLLEGE OF PHYSICIANS OF IRELAND AND ROYAL COLLEGE OF SURGEONS IN IRELAND.

**The Diploma in Public Health.**  
Every candidate for the Diploma in Public Health must observe the following rules:

Rule 1. A period of not less than two years shall elapse between the attainment by a candidate of a registrable qualification in Medicine, Surgery, and Midwifery and his admission to the Final Examination for a Diploma in Public Health.

Rule 2. The curriculum for the Diploma in Public Health shall extend over a period of not less than twelve calendar months subsequent to the attainment of a registrable qualification.

Rule 3. Every candidate shall produce evidence of having attended, over a period of not less than five months, at an institution approved by the Licensing Body granting the Diploma, practical instruction in—

(a) Bacteriology and Parasitology (including Medical Entomology), during a period of not less than five months, at an institution approved by the Licensing Body granting the Diploma, instruction in—

(b) Bacteriology and Parasitology (including Medical Entomology), especially in their relation to diseases of man, and to those of the lower animals which are transmissible to man;

(c) Chemistry and Climatology in relation to Public Health.

(d) Meteorology and Climatology in relation to Public Health.

(e) At least 180 hours must be devoted to Course (a), of which not less than 90 hours shall be devoted to practical laboratory work.

(f) At least 90 hours must be devoted to Course (b), of which not less than 45 hours shall be devoted to practical laboratory work.

(g) At least 10 hours must be devoted to Course (c), of which not less than 5 hours shall be devoted to practical laboratory work.

Rule 4. Every candidate shall produce evidence of having received, during not less than 80 hours, at an institution approved by the Licensing Body granting the Diploma, instruction in the following subjects—

(a) The Principles and Vital Statistics (20)

(b) Epidemiology and Law and Administration (including Public Medical Services) (20)

(c) Sanitary Construction and Planning (10).

(d) Sanitary Construction and Planning (10).

(e) The numbers indicate the normal proportion of time to be given to each subject.

Rule 5. Every candidate shall produce evidence that he has attended for three months on the clinical practice of a recognized Hospital for Infectious Diseases, and has received therein instruction in the methods of administration. At least thirty daily attendances of not less than two hours in each week shall be required.

**Rule 6.** Every candidate shall produce evidence that he has, during a period of not less than six months, been engaged in acquiring a practical knowledge of the duties, routine and special, of Public Health Administration under the supervision of a Medical Officer of Health, who shall certify that the candidate has received, from this Officer or other competent Medical Officer, during not less than three hours on each of sixty working days, practical instruction in these duties, and also those relating to:

- (a) Maternity and Child-Welfare Service;
- (b) Health Services for Children of School Age;
- (c) Venereal Diseases Service;
- (d) Tuberculosis Service;
- (e) Industrial Hygiene;
- (f) Inspection and Control of Food, including meat and milk.

Candidates of having received the prescribed instruction in Public Health Administration must be given by a Medical Officer of Health who devotes his whole time to Public Health work; or by the Medical Officer of Health of a Sanitary Area having a population of not less than 50,000, or in Ireland the Medical Superintendent Officer of Health of a County or County Borough having a population of not less than 50,000.

**Rule 7.** The examination for the Diploma shall be divided into two parts, Part I and Part II.

**Rule 8.** The examination for Part I shall include the following subjects:

- Bacteriology and Parasitology (including Medical Entomology);
- Chemistry and Physics, and Meteorology and Climatology; in relation to Public Health.

**Rule 9.** The examination for Part II shall include the following subjects:

- Hygiene and Sanitation (including Sanitary Construction);
- Epidemiology and Infectious Diseases;
- Sanitary Law and Vital Statistics;
- Public Health Administration.

The examination shall be written and oral, and shall include practical examinations in Infectious Diseases; Food inspection; Inspection of premises—dwellings, factories, workshops, schools, etc.

### ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

Those whose names already appear on the *Medical Register* can obtain the separate Licence in Medicine of this College, and its Licence in Midwifery. In either case an examination has to be passed in the subjects indicated, questions on midwifery, hygiene, and jurisprudence being included in the examination for the Licence in Medicine. For the Licence in Midwifery practitioners of over five years' standing are exempted from examination by printed questions. The other grades of the College are Members and Fellows. The former are admitted after an examination which is open to all university graduates in medicine and Licentiates in medicine of Royal Colleges of Physicians, and deals with the general subjects of medicine. Fellows are selected, by vote, from among the Members of the College, irrespective of sex.

**Fees.**—For the Licence in Medicine, 15 guineas; Special Examination, £21. For the Licence in Midwifery, 8 guineas; Special Examination 16 guineas. For the Membership, 20 guineas to a Licentiate of the College, 35 guineas to others; a special examination costs 10 guineas extra. The Fellowship, £35, in addition to stamp duty, £25.

Information as to special examinations and other matters can be obtained from the Registrar, the Royal College of Physicians, Kildare Street, Dublin.

### ROYAL COLLEGE OF SURGEONS IN IRELAND.

This body, besides granting a Licence in Surgery, admits those possessed of registrable surgical qualifications to its Fellowship under certain conditions. Its Licence is usually granted conjointly with that of the College of Physicians, but it is given separately to holders of a registrable qualification in medicine, provided the College is satisfied that adequate courses of study have been pursued, and provided its own provisional examination is passed. This examination is held on its behalf by the Conjoint Board, and is identical with the ordinary surgical portion of the examinations imposed by that body.

**The Fellowship.**—Candidates for the Fellowship must pass two examinations, of which the first is in anatomy (including dissections), physiology, and histology; and the second in surgery (including surgical anatomy) and pathology. Both examinations are partly written, partly practical, and partly *viva voce*; while the final examination includes the performance of operations. All subjects of either examination must be passed at one time, and in neither can a candidate be admitted who has been rejected in any of its subjects by any other licensing body within three months. Candidates are not admitted to the Primary Examination except on evidence that they have already passed an examination in anatomy, physiology, and histology, held by some university or other body whose degrees or licences entitle the holder to admission to the *Medical Register*; if, how-

ever, the candidate's name is on the Colonial or Foreign List in the *Medical Register*, at the discretion of the Council. Candidates for the final examination must be over 25 years of age, produce a certificate of general good conduct signed by two or more Fellows of the College, and, if successful, must make a declaration before admission to the effect that they do not conduct dispensing practices, and will not do so as long as they are Fellows.

**Fees.**—Candidates for the Licence pay 5 guineas for examination, which sum, if they pass, is counted as part of the fee payable on admission to the Licence, this being 25 guineas. Candidates for the Fellowship pay 5 guineas for each examination, the total of 10 guineas being reckoned as part of the fee payable on admission to the Fellowship. That fee is 25 guineas in the case of those who are already Licentiates, and 40 guineas in the case of others.

### APOTHECARIES' HALL OF IRELAND.

A DIPLOMA is granted by this Hall which entitles the holder to be registered as a practitioner of medicine, surgery, and midwifery, and confers also the privileges of an apothecary. Women candidates are eligible. We have received no response to our inquiries either last year or this year, but the fees in 1924 were as follows:

**Fees.**—Primary Examination, £10 10s.; Intermediate Examination, £10 10s.; Final Examination, £21; Final alone, when the others have been passed elsewhere, £26 5s.

Application for other information should be made to the Registrar, 95, Merrion Square, Dublin.

## MEDICAL SCHOOLS AND COLLEGES.

### LONDON.

INFORMATION as to the fees at each of the various metropolitan medical schools, and the scholarships, prizes, and junior appointments which they offer, will be found in the following pages. The courses they provide are fundamentally the same, and in all of them the arrangements made are such as to meet the requirements of students of every class—of those who are aiming at the diplomas of the English Conjoint Board or the Apothecaries' Society, not less than of those who have London or other university degrees in view. At all, too, special facilities are offered to students who have commenced their professional education at Oxford or Cambridge, and are seeking the medical degrees of those universities.

### CHARING CROSS HOSPITAL.

This school, with its hospital, is situated in the centre of London, and is easily accessible. Primary and intermediate students attend lectures and practical work at King's College. The final studies are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged to cover all the subjects necessary for the qualifying examinations. Departments are also available for the other final subjects of bacteriology, clinical pathology, biochemistry, materia medica, public health, operative surgery, and for research work. An Institute of Pathology, with a whole-time staff of scientific workers and fully equipped laboratories, has been established in the school. Students receive their training in preventive medicine, pathology, and bacteriology here, and are encouraged to undertake research.

Women students are admitted to the school and hospital upon the same terms and conditions as men, and after qualification are eligible for resident hospital appointments.

**Fees.**—The fees are as follows:—Entrance: Primary and Intermediate, 10 guineas; Final, 8 guineas. Annual, £42. Further information may be obtained on application to the Dean of the Medical School, Charing Cross Hospital, London, W.C.2.

### GRY'S HOSPITAL.

THE hospital contains 616 beds in constant occupation. Twenty-six beds are set apart for diseases of the eye, and 40 for the most urgent and interesting medical cases, which form the subjects of the weekly clinical lectures. There is a special ward of 32 beds for the reception of cases of

## LONDON MEDICAL SCHOOLS.

diseases of women and for cases of difficult labour. Beds are also allotted to the throat and ear departments, the departments of orthopaedics, neurology, and dermatology, the department for the treatment of diseases of the genito-urinary system, and the children's department; there are also some special beds for the treatment of syphilis.

The residential college fronts the east gate of the hospital, providing accommodation for resident students. This contains a dining hall, reading rooms, a library of general literature, and a gymnasium for the use of the residents and of the members of the Clubs Union. The athletic ground at Honor Oak Park is reached from the hospital in twenty minutes. The departments of chemistry, physics, pathology, and pharmacology, and the school buildings in Wills Library, the Gordon Museum of Pathology, the general, afford opportunities for a liberal education and research, and provide the full curriculum for a medical qualification. New departments of anatomy, physics, and biology were opened in July, 1925. They are equipped on modern lines, and provide ample accommodation for teaching and research. Special classes are held for the First and Second Examinations for medical degrees of the University of London, for the Pre-Medical Examination, and for the First and Final F.R.C.S. Eng. Special teaching is provided to meet the requirements of the Universities of London, Oxford, and Cambridge in general pathology and pharmacology.

**Appointments.**—All appointments are made according to the merits of the candidates, as determined by a committee of the medical staff. Sixteen out-patient officers, eight house-physicians, twenty assistant house-surgeons, eight house-surgeons, four ophthalmic house-surgeons, two genito-urinary house-surgeons, two house-physicians (children's department), and nine resident obstetric assistants are appointed annually. The house-physicians and house-surgeons, obstetric residents, ophthalmic house-surgeons, and genito-urinary house-surgeons hold office for six months each, and receive free board and lodging in the college. Every student is provided with rooms and commons in the hospital during the period of his "take in" as senior dresser. In addition to the clerkships and dresserships in the medical and surgical wards, students are appointed to the posts of clinical assistant, laryngology, gynaecology, diseases of children, diseases of the nervous system, special departments of ophthalmology, anaesthetics, dermatology, otology, actinotherapeutics, fractures, dentistry, orthopaedics, venereal disease; clinical assistant-ship and genito-urinary special departments are open to post-graduates.

**Scholarships, Prizes, etc.**—The following scholarships in Arts and Science are awarded. A. Open Junior Scholarships: (1) An Arts Scholarship of the value of £100, (2) a Science Scholarship of the value of £100; these are awarded annually in July. (3) A War Memorial Scholarship of the value of £200, awarded alternately in Arts and Science. This scholarship is open every other year; the next award will be made in July, 1928. B. Confined Scholarship in Science. A Junior Science Scholarship of the value of £100 is offered for competition annually in July to candidates who have attended the preliminary science classes at this school. Candidates for these scholarships: (1) A War Memorial Scholarship of £200, (2) an Open Scholarship of the value of £200, (3) an Open Senior Science Scholarship of the value of £200, (4) an Open Junior Science Scholarship of the value of £100, (5) a War Memorial Scholarship of the value of £100, (6) a Science Scholarship of the value of £100; both of these are awarded annually in September. Full particulars as to the scholarships may be obtained from the Dean of the Medical School. Junior prizes for general proficiency, £20, £15, £10; Hilton prize for Dissection, £5; Michael Harris prize for Anatomy, £10; Sands-Cox Scholarship for Physiology, £10; Beane prize for Pathology, £34; Treasurer's gold medal in Medicine, £25; Treasurer's gold medal in Surgery, £20, and the Gold Medal in Pathology, £20. The Beane Scholarship in Pathology of the value of £250 per annum, the Beane Travelling Scholarship in Materia Medica, of the annual value of £50, and the Anderson Demonstration prize for Bacteriology (£20), are awarded annually after competitive examination to enable research to be carried on in these subjects. An Arthur Durham Travelling Scholarship of £100 is awarded triennially. The Griffiths Demonstration prize for Pathology of the value of £320 per annum, and the Beane prize for Pathology of the value of £150 per annum, are awarded without examination. Further information may be obtained from the Dean of the Medical School, Guy's Hospital, London Bridge, S.E.1.

**KING'S COLLEGE HOSPITAL.**  
The medical school of this hospital, which is situated at Denmark Hill, deals with the final examination subjects of the medical curriculum. The hospital was opened in 1913, and is one of the most modern and best equipped in England. The number of attendances in the casualty and out-patient departments during the year 1925 amounted to 216,483. In the education at the hospital a special feature has always been the individual attention given to each student. The studies are co-ordinated under the direction of senior members of the honorary staff, assisted by medical, surgical, obstetric, and pathological tutors. There are special departments for diseases of women and children, nervous diseases, ophthalmology, otology, laryngology and rhinology, dermatology, radiology, and physiotherapy. The laboratory and pathological department are specially noteworthy.

**Appointments.**—Sixteen resident medical and surgical officers are appointed half-yearly, as well as dressers and clerks in the wards, out-patient departments, post-mortem rooms, and special departments. Each of the special departments has several clinical assistants. There are three registrars and four tutors, all of whom receive salaries. The Clubs and Societies Union combines athletics, music, and other societies connected with the school, and provides also a common room.

**Scholarships, etc.**—At entrance: Science Scholarship, £50. At commencement of Final Studies: Anatomy and Physiology Scholarship, £50; Pathology and Pharmacology Scholarship, £50; two Raymond Gooch Scholarships, each £60 a year for two years; two Burney Yeo Scholarships, each £20 (for Oxford and Cambridge students); Epsom College Scholarship, £50; Senior Scholarship, £40; Todd Prize, Tanager Prize, Class Prizes and Medals. Fees.—The composition fee is 93 guineas if paid in one sum. Entrance fee of 10 guineas includes membership of the Clubs and Societies Union.

**New Dental School.**—This school was opened in October, 1923, and provides complete courses for dental degrees and diplomas. The director of dental studies is Dr. A. Livingston, M.B., Ch.B., M.D.S. Liverpool.

The calendar of the school can be obtained on application to the Dean, H. Willoughby Lyle, M.D., F.R.C.S., or to the Secretary of the Medical School, S. C. Ranner, M.A., King's College Hospital, Denmark Hill, S.E.5.

## THE LONDON HOSPITAL.

This hospital, with its medical college and dental school, is situated in the Mile End Road, E.1. The hospital contains 950 beds, 849 of which number are in constant use. During 1925, 18,237 patients passed through the wards and 132,023 out-patients received treatment. Of the latter number, 41,834 received treatment in the departments for diseases of the ear, nose, throat, eye, skin, and teeth, and in the pediatric, orthopaedic, venereal, radiological, electro- and physio-therapeutic, and inoculation departments. The number of major operations which were performed amounted to 7,991.

The hospital presents, therefore, a large field for clinical instruction, and in its wards and out-patient and special departments exceptional opportunities are afforded of acquiring an extensive and practical experience of a whole phase of disease. A clinical unit in medicine, under the charge of a whole-time director, provides for the more elaborate methods of diagnosis and treatment, and takes a leading part in the initiation and surgical firm throughout the hospital there is attached a first assistant, who is responsible for instructing the clerks or dressers of the firm in elementary medicine and surgery, and who assists the honorary members of the firm in the preparation of their demonstrations. Special courses of lectures and demonstrations are arranged in medicine and surgery and in their ancillary subjects. Opportunities for research are provided under the supervision of the staff.

All the departments are modern and adapted for the teaching of all subjects in the various curricula. Special courses of instruction are held in preparation for the examinations of the University of London, for the Fellowship of the Royal College of Surgeons, and for the Membership of the Royal College of Physicians. Special

entries can be made for the medical and surgical practice of the hospital. A residential hostel on hospital ground is provided for the convenience of students who wish to live near the wards and casualty departments. The athletic ground, of over thirteen acres, is at Higham's Park, and is open to all members of the Clubs Union.

**Appointments.**—The salaried appointments open to past students of the hospital are those of assistants to the medical unit; first assistants to the medical and surgical firms; obstetric registrar; medical, surgical, and obstetric tutors; clinical assistants in the medical, surgical, ophthalmic, aural, light and skin, orthopaedic, and electrical departments, and in the Pathological Institute. There are appointed annually 4 resident accoucheurs, 14 resident house-physicians and 22 resident house-surgeons; 14 resident receiving-room officers, 8 resident emergency officers, 8 clinical assistants to the medical out-patient department, and 16 clinical assistants to the surgical out-patient department, also paid and unpaid clinical assistants in the various special departments. In addition, there are numerous assistantships, clerkships, and dresserships in the departments of medicine, surgery, gynaecology, and obstetrics.

**Scholarships and Prizes.**—The following is a list of scholarships and prizes:—At Entrance: Price Scholarship in Science, £100; Price Scholarship in Anatomy and Physiology, open to students of Oxford and Cambridge Universities, £75; Entrance Scholarship in Science, £50; Epsom Scholarship, "Free Medical Education." After Entrance: Buxton Prize in Anatomy and Physiology, £40; Letheby Prizes in Organic Chemistry and Chemical Pathology, £25; Prizes in Clinical Medicine, Surgery, and Obstetrics and Gynaecology, £20 each; Duckworth Nelson Prize in Practical Medicine and Surgery, £10; Hutchinson Prize in Clinical Surgery, £60; Treves Prize in Clinical Surgery, £15; Sutton Prize in Pathology, £20; K. E. D. Payne Prize in Pathology, £20; Sir Andrew Clark Prize in Clinical Medicine and Pathology, £26; Anderson Prizes in Elementary Clinical Medicine, £20; Dressers' Prizes, £40; Practical Anatomy Prizes, £10; Arnold-Thompson Prize in Medical and Surgical Diseases of Children, £15; Liddle Prize, £120; Francis Farmer Scholarship in Dental Surgery, £25; Harold Fink Prize in Dental Surgery, £8 8s. The "London" prizes in Dental Surgery and Pathology, £5 5s., and in Dental Prosthesis, £5 5s. Seven class examination prizes, each of the value of £3 3s., are offered for competition at the end of the courses of lectures in the dental curricula. Funds to the value of over £90,000 permit of financial assistance being given to students and graduates engaged in medical research.

**Fees.**—Entrance fee, 20 or 15 guineas, according to examinations passed; annual fee, 40 guineas.

Full information may be obtained from the Dean at the London Hospital Medical College, Mile End, E.1.

#### THE MIDDLESEX HOSPITAL.

The school and hospital are in Mortimer Street, W.1, close to Oxford Circus, Goudge Street, and Great Portland Street stations. There are a gymnasium, common rooms, and restaurant within the hospital precincts, and an athletic ground within easy reach. The hospital contains over 450 beds, including a wing containing 92 beds for patients suffering from cancer. There are special wards for maternity and gynaecological cases, for mental cases, for cases of venereal disease, and for diseases of children and of the skin and eye.

The medical school, which includes the Bland-Sutton Institute of Pathology and the cancer research laboratories, is completely equipped for teaching the entire medical curriculum, including the pre-medical subjects, chemistry, physics, and biology. The Bland-Sutton Institute, under the charge of the Professor of Pathology, contains large pathological and public health laboratories, a separate department of biochemistry, and smaller rooms for original investigation as well as a pathological and anatomical museum. Bacteriological, chemical, and microscopical examinations of material from the wards, operating theatres, and out-patient departments are carried out in the laboratories, and senior students are eligible for clerkships in connexion with this work. Junior assistants in the pathological and bacteriological laboratories are elected annually from recently qualified students. Every facility is given for original research. The cancer research laboratories offer unrivalled opportunities for the study of this disease, in both its clinical and pathological aspects.

**Appointments.**—Twenty-two resident appointments are open annually for competition among students of the hospital. The officers reside and board in the residential

college free of expense. Two casualty medical and two casualty surgical officers, and two resident officers to the special departments, are appointed annually. Eight house-surgeons are appointed every year at intervals of two months, after examination; six house-physicians are also appointed annually at similar intervals. An obstetric and gynaecological house-surgeon is appointed every six months. Nine registrars are appointed annually. In the out-patient departments the appointments are: clerk and dresser to the physicians and surgeons to out-patients; clerk in the departments for diseases of the skin and nervous diseases; dressers to the department for diseases of women, to the ophthalmic surgeon, to the throat and ear department, and to the dental surgeon. Extern midwifery clerks and *post-mortem* clerks are also appointed. The appointments are so arranged that every student may, during his course, hold all the out-patient and in-patient clerkships and dresserships. Students must have held an out-patient clerkship and dressership before holding in-patient clerkships or dresserships. Non-resident qualified clinical assistants are appointed in the medical, surgical, skin, neurological, ophthalmic, throat and ear, odontological, children's, and electrotherapeutic out-patient departments.

**Scholarships.**—There are two Entrance Scholarships, value £100 each. Two annual Entrance Scholarships, of the value of £90 and £60 respectively, are open to students of the universities of Oxford and Cambridge who have completed the curriculum for, or passed the examinations in, anatomy and physiology. Students joining the school in the previous April are eligible. The Freer Lucas Scholarship is annually awarded on the nomination of the headmaster to a pupil of Epsom College who has passed the first examination for medical degrees (Preliminary Scientific Examination). There is also a scholarship, value £50, awarded annually to students from New Zealand. In addition to the Entrance Scholarships, there are numerous other valuable scholarships, prizes, and exhibitions open to students of the hospital, including the Brodrip Scholarships, value £60 and £40; Lyell Gold Medal and Scholarship, value £55 5s.; Freeman Scholarship, value £30; John Murray Gold Medal and Scholarship, value £25; Hetley Clinical Prize, value £25; Leopold Hudson Prize, value 11 guineas; and the Second Year's Exhibition, value 10 guineas.

**Fees.**—(a) Pre-medical students: For one year or less, £21. (b) Students who have completed the Preliminary Science course: Entrance fee, 25 guineas; five annual fees of £45. The annual fee for further attendance at the medical school, if a registrable qualification has not been obtained, is £23. Three-quarters, one-half, or one-quarter of the last annual fee may, at the discretion of the School Council, be returned if the student obtains a registrable qualification within three, six, or nine months of the annual payment becoming due. (c) Oxford and Cambridge and other students who have completed the Intermediate course: Entrance fee, 15 guineas; two annual fees of £45; further annual fees as above. These fees are inclusive and cover the cost of instruction in vaccination, fevers, etc., and also the subscription to the amalgamated clubs and hospital Journal.

Further information may be obtained from the Dean or the School Secretary.

#### ST. BARTHOLOMEW'S HOSPITAL.

This institution fills one side of Smithfield and Giltspur Street, covering the greater part of a large island of ground separated practically from all other buildings; it is on the edge of the City, and easily reached from all parts of London. The hospital contains 757 beds. Extensive buildings, opened in July, 1907, occupy part of the ground acquired from the old Bluecoat School, and these materially enhance the attractions of the hospital as a place of medical study. The medical school buildings, including the library, the museum, and the chemical, biological, and anatomical departments, have now at their side a very large building, which includes club rooms for the Students' Union, a writing room, luncheon and dining halls, new quarters for the resident staff, and an out-patient department and accommodation for special departments of such large size as to be unsurpassed by any hospital in the kingdom. During the year 1909 a second block of new buildings was completed. These form the pathological department, and include, in addition to an extensive *post-mortem* room, large and well equipped laboratories for clinical pathology, pathological histology, bacteriology, and chemical pathology, altogether forming the most complete pathological department in the country. A further large block in Giltspur Street was acquired in 1923, and has been equipped by the construction of new lecture theatres and extensive laboratories for physics, chemical physiology, experimental physiology, histology, and pharmacology.

Within the precincts of the hospital there is also a residential college for a large number of students. The Students' Union owns grounds of some ten acres in extent for recreative purposes at Winchmore Hill, which is easily accessible from the hospital.

Special classes are held for students preparing for the Preliminary Scientific and other examinations, for the M.B., M.D. of the Universities of Oxford, Cambridge, and London, and for the higher surgical degrees at the same universities, including the M.Ch.Oxon., M.Ch.Cantab., M.S.Lond., and F.R.C.S.Eng.

**Clinical Units.**—Special clinical units have been established in medicine and surgery, each under the charge of a professor and director who devotes the whole of his time to the purpose of hospital practice, teaching, and research. In each unit there are an assistant director and four assistants, for whom special laboratory accommodation has been provided by a gift from the Sir William Dunn Trustees. The appointments of clerks and dressers are open to all students in these departments, and arrangements are made for all students to study in these units during a part of their clinical course.

**Appointments.**—Clinical clerks to the physicians and to the physician-accoucheur, and dressers to the surgeons and in the casualty department, are chosen from the students; clerks and dressers are also selected from the students to attend in the out-patient rooms, in the special departments (ophthalmic, orthopaedic, gynaecological, children's, laryngological, aural, dermatological, venereal, electrical and dental), and in the post-mortem room. Chief assistants and clinical assistants are selected from qualified men appointed yearly to help in the general medical, surgical, and in the special departments. Ten house-physicians and ten house-surgeons are appointed annually. During their first six months of office they act as "junior" house-physicians and house-surgeons, and receive a salary of £80 a year. During their second six months they become "senior" house-physicians and house-surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant, an ophthalmic house-surgeon, a house-surgeon to the skin and venereal department, and a house-surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Three resident administrators of anaesthetics are appointed—the senior for one year at a salary of £150, and two juniors for six months with a salary at the rate of £80 per annum—and all are provided with board and rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year.

**Scholarships.**—Four entrance Scholarships are annually awarded after examinations held in September. The subjects of examination and conditions of eligibility for these scholarships are: (1) One scholarship, value £75, in not fewer than two and not more than three of the following subjects: chemistry, physics, botany, zoology, physiology, pathology, and anatomy, limited to students under 25 years of age who have not entered on the medical or surgical practice of any London medical school. (2) One scholarship, value £100, in not fewer than three of the following subjects: chemistry, physics, botany, zoology, and physiology, limited to students under 21 years of age who have not entered on the medical or surgical practice of any London medical school. (3) An entrance scholarship in arts, of the value of £100, in Mathematics; Latin or Greek, or French or German; a second language or Chemistry or Physics. (4) The Jeaffers Exhibition in the same subjects as No. 3—of the value of £50. Candidates for Nos. 3 and 4 must be under 19 years of age. The total value of the scholarships and prizes is over £1,200 annually.

Further information and a handbook can be obtained on application to the Dean of the Medical College, St. Bartholomew's Hospital, E.C.1.

#### ST. GEORGE'S HOSPITAL.

This school is at Hyde Park Corner, and is carried on in connexion with St. George's Hospital, an institution having a service of 436 beds, of which 100 are at the convalescent hospital at Wimbledon. It provides for the instruction of its students in the preliminary and intermediate subjects of the curriculum at the teaching centre of London University established at King's College. The school at Hyde Park Corner is devoted entirely to the teaching of clinical subjects, great attention being paid by the members of the staff to individual teaching. A number of special

courses are given, in which the requirements of university and all other examinations receive careful attention.

The St. George's Hospital Club consists of an amalgamation club, with smoking and luncheon rooms on the hospital premises, and other students' clubs, with an athletic ground at Wimbledon. Students have the advantage of a well filled library of medical and scientific books. A register of accredited apartments and a list of medical men and others willing to receive St. George's men as boarders may be seen on application to the Dean.

**Appointments.**—Two house-physicians, two house-surgeons, and two casualty officers are appointed every two months. The house officers reside and board in the hospital free of expense. The casualty officers are non-resident, and receive salaries at the rate of £100 per annum. After the student has held a house appointment, the following are, among others, open to him: assistant resident physician at £350 per annum; assistant resident surgeon at £350 per annum; medical officer to the Atkinson Morley Convalescent Hospital at £300 per annum; medical registrarship at £200 per annum; surgical registrarship at £200 per annum; medical officer to the biochemical department at £100 per annum; assistant curatorship of the museum, £100 per annum; obstetric assistantship, resident, at £50 per annum; the post of resident anaesthetist at £100 per annum; the posts (two) of junior anaesthetist, each at £30 per annum.

**Scholarships.**—The following Entrance Scholarships and Exhibitions in anatomy and physiology and in general pathology are awarded in July to candidates who have passed the second M.B.London or corresponding examination: Senior William Brown Exhibition of the value of £150; Senior Scholarship of the value of 90 guineas; Junior William Brown Exhibition of the value of £80; Junior Scholarship of the value of £70; Devitt-Pendlebury Scholarship of the value of £50; and Exhibitions, each of the value of £40 and up to six in number. Other prizes to the value of £200 are awarded annually to the students of the hospital.

**Fees.**—First year (First M.B. or pre-medical course), £35 15s.; second and third years, £12 each. For the course of clinical study, in the fourth and subsequent years, entrance fee, £10 10s.; annual composition fee, £12. No entrance fee is payable by St. George's students who have studied at King's College.

Further information may be obtained from the Dean of the Medical School.

#### ST. MARY'S HOSPITAL.

This hospital and medical school are situated close to Paddington Station (G.W.R.), having on one side a poor district of 500,000 persons, and on the other side the residential district of Kensington and Bayswater. The hospital contains 288 beds, and, by a scheme of affiliation, for teaching purposes, of several neighbouring hospitals, the teaching facilities extend over 1,000 beds. By arrangement with the Lock Hospital, students take the courses of instruction in venereal diseases there. The athletic ground (ten acres) is situated at Wembley, and can be reached in twenty minutes by a constant service of trains; a large pavilion has recently been erected.

**Clinical Facilities.**—Clinical units in medicine and surgery were established in 1920, and have now been formally recognized by the University Grants Committee, St. Mary's being one of the six medical schools in London which enjoy this privilege. In addition to the lying-in beds at St. Mary's, every student attends a short course at Queen Charlotte's Maternity Hospital (which is situated near to St. Mary's) before holding a post on the maternity district of the hospital.

**Institute of Pathology and Research.**—Students specially interested in pathology and bacteriology have singular advantages at St. Mary's. The Institute comprises seven special departments, the whole being under the personal direction of Sir Almroth Wright, F.R.S. Research scholarships of £200 each are awarded annually to students working in the departments of the Institute; and research beds are provided. Clerkships in pathology and bacteriology and chemical pathology, lasting for a period of three months, are open to students of the fifth year, and enable them to carry out the pathological and bacteriological investigations of the wards, and learn the necessary technique under supervision. Seventy-two of these posts are available annually.

**Complete Curriculum.**—The medical school provides complete courses of instruction, and students can join at any

on passing a Preliminary Examination in Arts. Terms begin in October, January, and April.

**Entrance Scholarships.**—Two entrance scholarships of £210 each and one of £26 5s. are awarded annually in July by nomination on the lines of the Rhodes Scholarships. One or more University Scholarships of £200 are awarded annually in July.

**Fees.**—Composition fees for entire curriculum (5½ years), £200 in one sum, or £210 by five annual instalments. Composition fee for clinical curriculum (2½ years), 90 guineas in one sum, or 95 guineas by two annual instalments. As an alternative, students may pay an annual fee of 40 guineas, with an entrance fee of 10 guineas.

#### ST. THOMAS'S HOSPITAL.

This school and hospital are situated in Lambeth, on the south bank of the Thames, facing the Houses of Parliament, and form one of the well known architectural features of London.

The school buildings, which are separated from the hospital by a quadrangle, comprise lecture theatres, laboratories, and classrooms well adapted for the modern teaching of large bodies of students in the subjects of the medical curriculum. A splendid library and reading room and a complete museum are open to all students from 9 a.m. to 5 p.m., on Saturdays to 1 p.m. The Students' Club premises contain a dining room and smoking and reading room supplied with daily and illustrated weekly papers, and a gymnasium. Good meals are obtainable at a moderate tariff. A new Residential Club for students, now being erected, will be opened early in 1927, and will provide resident quarters for some sixty students. The terrace affords facilities for exercise and recreation. The sports ground, of more than nine acres in extent, is at Chiswick. It can be reached in forty minutes from the hospital; it is admirably adapted for football, cricket, lawn tennis, and athletic sports.

The hospital proper contains 644 beds. In addition to the ordinary provisions of a great hospital there are connected with the out-patient department physicians' and surgeons' rooms provided with ample sitting accommodation, so that students are enabled to follow closely the practice and teaching of the out-patient staff. There is a full complement of special departments, and connected with the hospital a special tuberculosis department gives opportunity for instruction of students. There is a clinical theatre, centrally situated, so as to facilitate the illustration of lectures by patients from the wards and out-patient room; it is arranged also for lantern demonstrations. The maternity ward, containing 21 beds, gives students full facilities for maternity training, under supervision, within the precincts of the hospital. This obviates any necessity for supplementary instruction elsewhere, and fully prepares the student for the extern maternity practice of the hospital district. The revised regulations of the examining bodies can thus be fully complied with.

**Appointments.**—All hospital appointments are open to students without charge. A resident assistant physician, a resident assistant surgeon, and a resident anaesthetist are appointed annually at a salary of £200 each per annum. Two hospital registrars, medical and surgical, at an annual salary of £250 each, are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. A pathological registrar to the department of obstetrics and gynaecology (at an annual salary of £250), an ophthalmic registrar (at an annual salary of £50), and an orthopaedic registrar (unpaid) are appointed yearly. Ten resident casualty officers and anaesthetists (including two senior) are appointed every six months. Seven house-physicians (including two obstetric house-physicians and one house-physician to the department of diseases of children) and nine house-surgeons (including two ophthalmic house-surgeons, one orthopaedic house-surgeon, and two house-surgeons to the ear, nose, and throat department) are appointed every six months. Thirty-six or more clinical assistants in the special departments are appointed every three months, and hold office for six months if recommended for re-election. Clinical clerkships and dresserships to the in-patient and out-patient departments are available to the number of 400 each year.

**Scholarships.**—There are five entrance Scholarships: Two in arts, giving one year's free tuition; one of £150 and one of £60, in chemistry, physics, and biology, for students who have not received instruction in anatomy or physiology; one of £100 in any

two of the following subjects: anatomy, physiology, chemistry, or pathology, for students who have completed their examinations in anatomy and physiology, for a medical degree in any of the universities of the United Kingdom or the Colonies, and have not entered as clinical students in any London medical school. The money value and subjects of examination of the remainder are as follows: (a) William Tite Scholarship for second-year students, £25; (b) and (c) Musgrove Scholarship or (alternately) Peacock Scholarship, each for third-year students and tenable for two years, £35 each; (d) Mead Medal, Medicine, Pathology, and Hygiene; (e) Wainwright Prize, Medicine; (f) Toller Prize, Medicine; (g) Cheselden Medal, Surgery and Anatomy; (h) Clutton Memorial Medal in Clinical Surgery, biennial; (i) Beaney Scholarship, £50 biennially, Surgery and Surgical Pathology; (j) Solly Medal and Prize, biennially, Reports of Cases; (k) Sutton Sams Prize, biennially, Reports of Cases; (l) Bristowe Medal, Pathology and Morbid Anatomy; (m) Hadden Prize, Pathology and Morbid Anatomy; (n) Grainger Testimonial Prize, £31 10s., Anatomy and Physiology; (o) Louis Jenner Research Scholarship, tenable for two years, £60 annually, Pathology; (p) School Council Research Scholarship, £250 per annum; (q) John and Temple Research Scholarship, value £450 per annum (children).

**Fees.**—The annual fees are: For each year of study, £50. These fees cover all tutorial classes, but do not include instruction in infectious fevers, pharmacy, and vaccination. Qualified practitioners are permitted to attend the hospital practice on terms which may be ascertained from the Medical Secretary.

Special courses of instruction are given for various examinations, and a register of lodgings is kept at the school. Further information may be obtained from the Medical Secretary of the School, St. Thomas's Hospital, Albert Embankment, S.E.1.

#### UNIVERSITY COLLEGE HOSPITAL.

The school, which forms part of the corporation of University College Hospital, is in immediate proximity to the hospital in University Street, and opposite University College. It comprises departments of medicine and clinical medicine, surgery and clinical surgery, midwifery and gynaecology, pathology including morbid anatomy, chemical pathology, biochemistry and bacteriology, cardiology, forensic medicine, mental physiology and mental diseases, dental surgery, practical pharmacy, and other departments for the study of special diseases, such as those of the eye, skin, ear and throat, venereal diseases, and for instruction in anaesthetics, electrotherapeutics, and skiagraphy. The Hospital and School have acquired the National Dental Hospital and College as their dental departments, thus providing every facility for the study of dental subjects. The Royal Ear Hospital, Dean Street, Soho, has also been amalgamated as the Ear, Nose, and Throat Department, and a new hospital for in- and out-patients, close to University College Hospital, is nearly completed.

The school thus provides the final course of study for the degrees of the Universities of Oxford, Cambridge, London, Durham, and other British universities, and for the diplomas of the Royal Colleges of Physicians and Surgeons in Medicine and Dental Surgery, and the Licence of the Society of Apothecaries. Special bacteriological classes are also held in preparation for the various diplomas in public health. Each department is also equipped for more advanced work, and provides facilities for research.

Clinical units in medicine and surgery are now in operation. The whole-time directors of the units are concerned with the organization of the teaching generally, but the honorary staff is responsible for the largest share of the teaching in the wards and out-patient department of the hospital. A unit in obstetric medicine has been established now that the new obstetric hospital is finished.

The new buildings of the obstetric hospital of 60 beds (rendered possible by the Rockefeller benefaction), the new Residents' House (with accommodation for 30 residents and students), the extension of the Nurses' Home, and the new research laboratories for the Medical School, are now finished and in full occupation.

**Appointments.**—The qualified appointments, in addition to a number of posts as house-physicians and house-surgeons and obstetric assistants, include the appointments of resident medical officer, medical registrar, surgical registrar, obstetric registrar, Harker Smith radium registrar, ophthalmic registrar, casualty medical officers, casualty surgical officers, assistants in ear, nose and throat, skin and venereal diseases departments, and house anaesthetists.

**Scholarships.**—The following scholarships and prizes are open to competition: Two Entrance Exhibitions of 112 guineas each, awarded after a competitive examination in anatomy or physiology, or General Pathology, Radcliffe Crocker Travelling Scholarship in dermatology for one year, value about £280; the Graham

scholarship in pathology of a sum not exceeding £300 per annum; Leslie Pearce Gould Research Scholarship in surgery for one year, value about £200; the Atkinson Morley Scholarship of £45 a year for three years, awarded after examination in the theory and practice of surgery; the Atchison Scholarship of £55 a year for two years for general proficiency in medical studies; the Magrath Clinical Scholarship, value about £150; the Pillitter Exhibition in pathology of £30; the Percival Allyn Prize for the advancement of surgery by research, value about £75; the Graham Gold Medal for research work; four Fellows Medals in clinical medicine; Liston Medals in clinical surgery; the Bruce Medal in pathology and surgery; two Tuke Medals in pathology; and the Erichsen Prize for practical surgery.

**Fees.**—The fee for the full course of final studies at the school is 112 guineas if paid in one sum, or 115 guineas if paid in two instalments. Fees for vaccination, fevers, and pharmacy not included.

Particulars of general and special courses can be obtained on application to the Dean of the Medical School, University College Hospital, University Street, W.C.1.

#### WESTMINSTER HOSPITAL.

This school, with its hospital, situate in Broad Sanctuary, opposite Westminster Abbey, provides for the education of its students in the preliminary and intermediate subjects of the University of London at King's College. The rest of the work is done in the school buildings near the hospital. The number of in-patients averages 3,500 and out-patients upwards of 30,000 annually, and the hospital and school afford ample facilities for instruction in all branches of medicine and surgery.

**Appointments.**—A medical and surgical registrar are appointed annually, each with a salary of £150, and obstetric registrar with a salary of £50. A senior resident and casualty officer, salary £104 per annum and board, appointed for six months, may be extended for a further period of six months. Three house-physicians, three house-surgeons, three assistant house-physicians, three assistant house-surgeons, and a resident obstetric assistant are appointed after examination, and are provided with rooms, commons, and salary of £52 per annum, except the assistant house-physicians and the assistant house-surgeons, who are provided with commons only. The assistant house-physicians, after three months' service, become house-physicians for a further period of six months, and the assistant house-surgeons, after three months' service, become house-surgeons for a further period of six months. Two house-anaesthetists are appointed for three months, non-resident, salary £50 per annum. Clinical assistants to the assistant physicians and assistant surgeons, and to the officers in charge of special departments, are appointed from among the qualified students. Every student must perform the duties of out-patient dresser for three months, and afterwards hold the office of in-patient dresser for three months. He is also required to serve two terms of three months each as medical clinical clerk to the in-patient physician and one term as gynaecological clinical clerk. Two pathological clerks are appointed every three months to assist in the post-mortem room. No student is eligible as an in-patient dresser or clinical clerk until he has passed the Second Examination of the Conjoint Board, or an equivalent examination. Clerks and dressers in the special departments of hospital practice are periodically appointed. So far as vacancies permit, students of other hospitals are admitted to in-patients' dresserships or clerkships.

The governors of the hospital have now completed the extensive improvements and alterations to the hospital, which render it a still more efficient teaching institution, with an increased number of beds.

**Scholarships.**—The following open scholarships are offered for competition during the year 1926-27: In the winter session two scholarships in anatomy and physiology, £70 each. In the spring two scholarships in anatomy and physiology, £70 each. A certain number of scholarships have been allotted to universities of England, Wales, and the Colonies, and to public schools. These scholarships are awarded entirely on the nomination of the Principal of the university or school.

**Fees.**—The annual composition fee is £40. An entrance fee of 10 guineas is payable by all students—namely, primary and intermediate students, £10 10s.; students entering for the final subjects, £8 2s. These fees include subscriptions for membership of the Club Union.

Further information and a prospectus can be obtained on application to the Dean at the Westminster Hospital, Westminster, S.W.1.

#### LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.

The school is situated at 8, Hunter Street, Brunswick Square, W.C.1, close to the Royal Free Hospital. It is, like all the other London schools which have so far been mentioned, one of the constituent schools of London University. The school buildings have recently been enlarged. The laboratories are extensive and well lighted, and are fully equipped for the examination courses of the University of London and the Royal Colleges of Physicians and Surgeons. Research laboratories are attached to all departments. A large, well equipped library, common room, Union room, and refectory are provided for the use of students. Resident accommodation for 60 students is provided in students' chambers attached to the school.

The Royal Free Hospital, Gray's Inn Road, W.C.1, has 240 beds, all of which are available for clinical instruction. A new block contains the obstetrical and gynaecological unit, which controls 68 beds. A large maternity district is served from the unit with a separate maternity hostel in the Essex Road, Islington. There are separate departments for diseases of the eye, ear, and skin, infant welfare, venereal diseases, massage, electrical and x-ray work, dentistry, and casualty. The instruction given covers the full curriculum for the M.B., B.S. degrees of the University of London, including first medical courses. Students attend the practice of one of the fever hospitals of the Metropolitan Asylums Board and receive special instruction in lunacy at Bethlem Hospital; they are also admitted to the practice of a number of special hospitals, and hold clerkships and dresserships at the Elizabeth Garrett Anderson Hospital, the Cancer Hospital, Hospital for Sick Children, the National Hospital for Nervous Diseases, the South London Hospital, and the Royal Ophthalmic Hospital. The work of the school includes preparation for the Primary Fellowship examination, and also for the Medical School and general hospital course for dental students.

**Appointments.**—Qualified students of the school can obtain appointments as house-physicians and house-surgeons, obstetric assistants, surgical, gynaecological, and medical registrars, assistant pathologists, assistant anaesthetists, medical electrician, skiagrapher, and clinical assistants and demonstrators in various subjects.

**Scholarships.**—The Isabel Thorne Entrance Scholarship, value £30, the St. Dunstan's Medical Exhibition, value £60 a year for three years, which may be extended to five years, the Alfred Langton Scholarship of £50 a year for two years, the Flora Murray Bursary of £50, and the Mabel Sharman-Crawford Scholarship value £20 a year for four years, are offered for competition in each year. The Sir Owen Roberts Memorial Scholarship of the value of £75 a year for four years, the Mrs. George M. Smith Scholarship of the value of £50 a year for three years, which may be extended to five years, the Dr. Margaret Todd Scholarship of the value of £37 10s. a year for four years, and the Sarah Holborn Scholarship of the value of £20 a year for three years, which may be extended to five years, are awarded in alternate years. The School Jubilee Bursary of £50 a year for three years is offered every third year. The Dostock Scholarship, value £30 a year for two or four years, is awarded by the Reid Trustees on the result of an examination held in May by the University of London every fourth year. The holder of the scholarship must enter the London School of Medicine for Women. The Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship, of the value of £25 a year for four years, is awarded every fourth year. The John Byron Bursary of £20 a year for two years, the Julia Anne Hornblower Cock Prize of £60, the Helen Prideaux Prize of £50, the Mabel Webb Research Scholarship of £30 for two years, the Fanny Butler Scholarship of £16 a year for four years, together with many other scholarships and prizes, are offered on sundry conditions. The Dr. Edith Pechey-Plumson Post-Graduate Scholarship of £100 is awarded annually. Altogether the School offers annually £1,350 in scholarships. Various missionary societies also offer scholarships on certain conditions, and assist ladies who wish to go to India and other countries as medical missionaries.

**Fees.**—Courses for the University of London degrees and the diplomas of the Conjoint Board in England, and other qualifications: £240, payable in five instalments. These sums include library and laboratory fees.

The Students' Union exists to promote corporate action of the students on matters of common interest, to promote and maintain athletic and other clubs, and to issue a school magazine. All students are required to become members of the Union. The students' sports ground, which consists of a freehold property of six and a half acres, is situated at Sudbury.

Further information can be obtained from the Warden and Secretary.

## KING'S COLLEGE.

In the Faculty of Medical Science instruction is given in the preliminary and intermediate subjects of the first and second examinations leading to the degree of M.B., B.S. of the University of London, of the corresponding examinations of other universities, and of the Conjoint Examining Board of the Royal Colleges of Physicians and Surgeons, including the primary examination for the F.R.C.S. Eng. The courses are open to women students on the same terms as to men.

Regular students who have completed their preliminary and intermediate examinations proceed to a hospital to pursue their studies for the final examinations. The hospitals associated with King's College are: King's College Hospital, Denmark Hill, S.E.5; Westminster Hospital, S.W.1; St. George's Hospital, Hyde Park Corner, S.W.1; and Charing Cross Hospital, Strand, W.C.2.

A course for the degree of the University of London and for the diploma of the Royal College of Surgeons in dental surgery in conjunction with King's College Hospital Medical School has been arranged.

*Scholarships.*—The entrance Scholarships are: (1) Two Warneford Scholarships, each £30 for four years; subjects—selected from mathematics, classics, divinity, and science. (2) One Sambrook Scholarship of £30 for three years; subjects of examination selected from mathematics, classics, and science. The holders of the preceding awards must proceed to King's College Hospital. (3) Worsley, £100, paid in five annual instalments. (4) Rabbeth Scholarships, value £30 and £15, in July, for the best student of the first year. (5) Second year's scholarship, value £20, for the best student of the second year. (6) Daniell Scholarship £30, awarded on the results of the University Honours Examination.

Full information as to admission, fees, and scholarships can be obtained from the Dean of the Faculty of Medical Science (Professor E. Barclay-Smith), King's College, Strand, W.C.2.

## UNIVERSITY COLLEGE.

This institution, one of the principal component parts of the University of London, possesses a Faculty of Medical Sciences whose work covers all the subjects included in the group commonly known as the preliminary medical sciences—namely, physics, chemistry, botany, and zoology; and also the intermediate medical sciences—namely, anatomy, physiology, and pharmacology. The new anatomy building, provided by the munificent gift of the Rockefeller Foundation of New York, was opened on May 31st, 1923, by His Majesty the King. This building forms part of the block which includes physiology and pharmacology. The department of hygiene and public health prepares for the diplomas in public health of the Royal Colleges and of the various universities. Research work is undertaken in all the above-named departments. The College undertakes the education of students in all the subjects mentioned, leaving them free to complete their education in the strictly professional subjects—medicine, surgery, and the like—at any one of the recognized schools of advanced medical studies. The work is somewhat differently arranged, according to whether the student has in view the degrees of the University of London or the diplomas of the Royal Colleges. In either case the whole work to be done is divided into courses devised to meet the requirements of different examinations, and students can join the College for any of them. Women students are admitted to all courses on the same terms as men. The general arrangements for the benefit of students include membership of the Union Society or the Women's Union Society with the College gymnasium and the athletic grounds. There is also a collegiate residence for about fifty-five men students at Ealing, and for about seventy women students at Byng Place, Gordon Square.

*Scholarships.*—The scholarships and exhibitions obtainable include the Bucknill Scholarship, value 135 guineas, in chemistry, physics, botany, and zoology (the successful student must complete his work at University College Hospital Medical School), and two entrance exhibitions in the same subjects, each of the value of 55 guineas.

*Fees.*—The fees for the courses covering the work of the First Examination for medical degrees of the University of London, and in both parts of the Second Examination, amount to 115 guineas. The fees for the courses covering the corresponding examinations held by the Conjoint Board in England also amount to 115 guineas. These fees may be divided into payments for the different courses

which it may be desired to take out, but do not cover tuition for more than a stated period.

A handbook specially relating to this faculty may be obtained on application to the Secretary of University College, Gower Street, London, W.C.1.

## THE PROVINCES.

THERE are in England and Wales, not counting London, ten medical schools, each supplying instruction in the full medical curriculum. Accounts of them here follow. In several cases there is appended information about hospitals other than those directly connected with the school in question; such hospitals, officially and unofficially, play a part in the education which the students of the school receive, and in any case serve as places of additional or post-graduate study.

## OXFORD AND CAMBRIDGE.

At both Oxford and Cambridge there are medical schools which furnish unsurpassed opportunities for obtaining a good knowledge of the preliminary sciences and of anatomy, physiology, and pathology. The laboratories are excellently furnished, and the teaching staffs most distinguished. Both schools provide a full medical curriculum, and there is no essential reason why the student should not complete his career at either of them; but this is not commonly done, and is never in the ordinary way advised by the university medical authorities. The local hospitals, though well equipped, are comparatively small. Students are therefore encouraged, as soon as they have completed the earlier examinations and taken a degree in arts, to join some London school, and thus spend the time of their preparation for the final examinations in a city where the opportunities for gaining clinical knowledge are greater and more varied. A considerable proportion of Oxford and Cambridge medical students take the London Conjoint diplomas before graduating in medicine and surgery at their own university. The experience gained by holding resident hospital appointments is naturally of much advantage when sitting for the Final M.B. examination and when engaged in composing a thesis.

## BIRMINGHAM.

THE school in this city is carried on by the Medical Faculty of the University of Birmingham, its students having an adequate number of good laboratories, classrooms, and other necessities devoted to their use by the university. The clinical work is done at the General and Queen's Hospitals, which are amalgamated for this purpose. Together they have upwards of 600 beds for medical, surgical, and special cases, and with an array of special departments of all kinds, including one for lying-in women. Clinical instruction is given in the wards and out-patient and special departments daily, and formal clinical lectures delivered weekly throughout the winter and summer sessions. Special tutorial classes are also held alike for the degrees of Birmingham and some other universities and for the diplomas of corporations.

*Appointments.*—The large number of appointments open to past or other students includes the following:—At the General Hospital: surgical registrar; £200 a year; one resident medical officer, salary £155 a year; one resident surgical officer, salary £180 a year; one assistant resident surgical officer, salary £100 a year; one resident pathologist, salary £70 a year; two visiting anaesthetists, salary £50 a year; one resident anaesthetist, salary £70 a year; four house-surgeons, office tenable for nine months, £70 a year; one house-surgeon to the gynaecological and one to the special departments, each tenable for six months, £70 a year; four house-physicians, post tenable for six months, £70 a year. At the Queen's Hospital: one medical registrar and one surgical registrar, non-resident, tenable for three years, renewable, salary £100 per annum; three house-physicians, three house-surgeons, and one obstetric and ophthalmic house-surgeon, tenable for six months, salary £70 per annum, with board, lodging, and washing; one casualty house-surgeon, tenable for three months, salary £70 per annum, with board, lodging, and

washing. At the Maternity Hospital: three house-surgeons, salary £50 a year. At the City Workhouse and Workhouse Infirmary: five resident medical officers. At the Birmingham General and Branch Dispensaries: twelve resident surgeons. At the Birmingham Mental Hospitals: five assistant medical officers. At the City Fever Hospitals: three assistant medical officers. At the Children's Hospital: one resident surgical officer, one resident medical officer. At the Birmingham and Midland Eye Hospital: four resident surgeons. At the Orthopaedic and Spinal Hospital: two clinical assistants (non-resident). At the Ear and Throat Hospital: one house-surgeon, £70 a year; four clinical assistants (non-resident). Four non-resident Poor Law appointments are in the gift of the Board of Guardians.

**Scholarships.**—There are numerous money and other awards for students of sufficient merit, among them being the following: The Walter Myers Travelling Studentship of £300, offered each alternate year and tenable abroad (offered next in 1927); the Sands-Cox Scholarship of £42 (an entrance scholarship in the Faculty of Medicine, awarded on Higher School Certificate Examination of the Joint Matriculation Board (July)); four Queen's Scholarships of £10 10s. each, awarded annually at the first (Part II), second, third, and final university examinations respectively; one or more Sydenham Scholarships, allotted on entrance to students who are the sons of deceased medical men; the Ingleby Scholarships (two) of £10 for proficiency in midwifery and diseases of women; the Arthur Foxwell Memorial Gold Medal (Clinical Medicine); the Sampson Gamgee Memorial Medal for Surgery (Final M.B.); and the Peter Thompson Prize in Anatomy (value about £6) for students in their second university year. There is also a scholarship of £37 10s. for students proceeding to a degree in dental surgery. University Clinical Board Prizes are awarded annually as follows: Senior Medical Prize, Gold Medal; Senior Surgical Prize, Gold Medal; Midwifery Prize, Gold Medal; Junior Medical Prize, Silver Medal; Junior Surgical Prize, Silver Medal.

**Fees.**—The composition fee for university classes is £106 5s. This covers all the work required for the degrees of Birmingham and some other universities, and for the ordinary qualifications of licensing corporations, but not the additional courses required for the Fellowship of the Royal College of Surgeons of England, the diploma and degrees of the university in State medicine, and some other special work. The total cost for the five years' curriculum, including hospital and examination fees, is estimated at £201 4s. 6d.

Other information should be sought from the Dean of the Medical Faculty, University, Edmund Street, Birmingham.

#### BRISTOL.

The school is carried on by the Faculty of Medicine of the university, and provides full instruction for all its degrees and diplomas.

**Clinical Instruction.**—The allied hospitals (Bristol Royal Infirmary and Bristol General Hospital) have between them about 600 beds and extensive out-patient departments, special clinics for diseases of women and children, and those of the eye, throat, and ear, in addition to large and well equipped departments for dental work and large outdoor maternity departments. At each of these institutions there are well arranged pathological museums, *post-mortem* rooms, and laboratories for morbid anatomy. There are also laboratories for work in clinical pathology, bacteriology, and cytology, in which special instruction is given in these subjects. Departments are provided and well equipped for x-ray work, both for diagnosis and treatment, the various forms of electrical treatment, including high-frequency currents, electric baths, Finsen light treatment, and massage. The students of the school also attend the practice of the Royal Hospital for Sick Children and Women, containing 108 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is therefore about 750.

**Appointments.**—(1) Undergraduate: Clinical clerkships, dresserships, also ophthalmic, obstetric, pathological, ear, nose, and throat clerkships, are tenable at the Bristol Royal Infirmary and the Bristol General Hospital. In these institutions the dressers reside in rotation free of charge. (2) Post-graduate: At the Bristol Royal Infirmary: four house-surgeons, £80 each per annum; two house-physicians, £80; two resident obstetric officers, one of whom is also ophthalmic house-surgeon, £100 and £80; ear, nose, and throat house-surgeon, £80; dental house-surgeon, £80. All these appointments are made for twelve months. From the resident officers a senior resident officer is appointed at a salary of £200. At the Bristol General Hospital: senior resident medical officer, £250 per annum; casualty house-surgeon, £80 per annum; two house-physicians, £80 per

annum; house-surgeon, £80 per annum; special obstetric physician, £80 per annum; house-surgeon to special departments, £80 per annum; dental house-surgeon, £300 per annum. All these appointments are for six months, except that of senior resident medical officer, which is for two years.

**Scholarships.**—The following are among the scholarships and other awards open to students of the school: The Ashworth Hallett Scholarship, value £45, open to women only; two Martyn Memorial Pathological Scholarships of £10 each; the Tibbitts Memorial Prize, value 9 guineas, for proficiency in practical surgery; the Committee's Gold and Silver Medals for fifth-year students for general proficiency; the Augustin Prichard Prize, value about 6 guineas, for proficiency in anatomy; the Henry Clark Prize, value 11 guineas, for proficiency in gynaecology; the Crosby Leonard Prize, value 7 guineas, for proficiency in surgery; the Suple Surgical Prize, a gold medal and 7 guineas; the Suple Medical Prize, a gold medal and 7 guineas; the Henry Marshall Prize, value £12, for dressers; the H. M. Clarke Scholarship, value £15, for proficiency in surgery; the Sanders Scholarship, value £22 10s., for general proficiency; the Barrett-Roué Scholarship for proficiency in diseases of the eye, ear, nose, and throat, value £14; Lady Haberfield Scholarship, value about 25 guineas; Phyllis Siepmann Prize for proficiency in diseases of children, value £50. Bristol City Senior Scholarships and the Senior Scholarships offered by the counties of Gloucestershire, Somerset, Wilts, Devon, etc., are tenable in the university.

Some of the Fellowships awarded by the Colston Research Society for research in the university are allotted to the Faculty of Medicine.

**Fees.**—The fee for all the courses required for the medical curriculum, including hospital practice, is 205 guineas, paid by annual instalments.

#### UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

This, the Medical School of the Faculty of Medicine of the University of Durham, is in the neighbouring city, Newcastle-on-Tyne. Its classes and lectures are arranged to meet the requirements of the university in all the degrees which the latter grants, and also those of the other examining bodies. The students do their work in the preliminary sciences at Armstrong College, also part of the university, and their clinical work in the Royal Victoria Infirmary, an institution with about 550 beds and special accommodation for the benefit of students. Students do their practical midwifery at the Princess Mary Maternity Hospital, which contains 90 beds, is thoroughly up to date, and there is an annual indoor and outdoor attendance on 3,000 cases. In a Heath wing of the school itself there is the department of physiology. There are also in this wing a gymnasium and a set of rooms for the use of the Students' Union. A new bacteriological department has recently been erected adjacent to Armstrong College.

**Post-Graduate Instruction.**—A comprehensive series of post-graduate courses has been arranged to enable practitioners to take advantage of the facilities for laboratory work and clinical study which are afforded by the College, the Royal Victoria Infirmary, and other associated hospitals, and in order to meet the varied requirements of practitioners there are general and special courses in the winter and summer session as well as an intensive course in the summer vacation.

**Students' Union.**—Students' Union Buildings have been erected and furnished at a cost of over £40,000, and are now in daily use. Separate accommodation (non-residential) is provided for men and women students.

**Appointments.**—Pathological assistants, and assistants in the eye department, throat and ear department, and department for skin diseases, are elected periodically. Clinical clerks and dressers are appointed every three months.

**Scholarships.**—University of Durham Entrance Scholarship, £25 a year for four years; Pears Entrance Scholarship, £30 a year for three years (awarded every third year); Province of Durham Masonic (Entrance) Scholarship, £60; Heath Scholarship for surgery, £200, available every second year.

The following scholarships are tenable for one year—namely, Tulloch Scholarship for elementary biology and organic chemistry, £20; Dickinson Scholarship for medicine, surgery, midwifery, and pathology, Gold Medal and £20; Charlton Scholarship for medicine, £25; Gibb Scholarship for pathology, £25; Luke Armstrong Scholarship for comparative pathology, £25; Stephen Scott Scholarship for surgery, £40; Philipson Scholarships for highest marks in Final M.B., B.S. Examination, two of £48 each; Goyder Memorial Scholarship for clinical medicine and clinical surgery, interest on £325; Gibson Prize for midwifery and diseases of women and children, £10; Turnbull Prize and Silver Medal for surface anatomy; Outtersen Wood Prize for psychological medicine, £10; and Sewell Memorial Prize and Silver Medal for clinical pathology.

At the end of each session a prize of books is awarded in each of the regular classes.

**Fees.**—The composition fee for lectures at the college is £122. Composition fee for hospital practice, £46, plus £2 2s. yearly for three years, payable to the Committee of the Royal Victoria Infirmary. Other information should be sought from the Registrar of the College of Medicine at Newcastle.

#### LEEDS.

THE School of Medicine—which is open to both male and female students—in this city forms the teaching centre of the Medical Faculty of the University of Leeds, and is situated in immediate proximity to the General Infirmary, where students sufficiently advanced receive their clinical instruction. The buildings were opened in 1894, and contain excellent dissecting rooms, several well arranged laboratories for physiology, pathology, and bacteriology, three lecture theatres, and several similar classrooms. In addition, there are a library and reading room and two museums, one being devoted to pathology and the other to anatomy. The comfort of the students is secured by common rooms and a refectory in which they can take meals. The General Infirmary has 632 beds, and includes gynaecological and ophthalmic wards, a special children's ward, and a large out-patient department. The Ida and Robert Arthington Semi-convalescent Hospitals, Cookridge, attached to the infirmary, have 88 beds. The West Riding Mental Hospital at Wakefield is open for the study of mental diseases. Students can, in addition, attend the practice of the Leeds Public Dispensary, the Hospital for Women and Children, and the Leeds Maternity Hospital, where the obstetric work is done.

**Appointments.**—Surgical dressers are appointed every six months; physicians' clerks, ophthalmic and aural dressers, gynaecological ward clerks, gynaecological out-patient clerks, maternity clerks, assistant physicians' clerk, dermatological clerks and assistant surgeons' dressers, dressers in the casualty room, *post-mortem* clerks, and laboratory assistants every three months, and dressers in the venereal clinic every month. After graduation there are a considerable number of residential and other appointments available in the Leeds General Infirmary, Leeds Public Dispensary, Hospital for Women and Children, West Riding Mental Hospital, etc., occupying periods of from six to twelve months at rates varying from £20 to £150 per annum.

**Scholarships.**—The university awards annually a scholarship in the form of a free admission to the lectures and classes given in the university, which are covered by the composition fee. The university also awards a scholarship on the results of the first examination, of the value of £68, in the form of a free admission to the clinical teaching of the infirmary.

**Fees.**—It is estimated by the authorities that the approximate cost of medical education to a student in this university is £300, plus, of course, the expenses of living during the five years covered by the curriculum. The fee for a complete course for the First M.B. is £41; the composition fee for the course for the second and third examinations, and for the clinical work at the infirmary, is £174. The composition and clinical fee for those who have passed the second examination is £138.

Further information can be obtained from the Academic Subdean or Clinical Subdean, School of Medicine, Leeds.

#### LIVERPOOL.

THE Medical School of this city is part of the university, and, owing to the enlightened liberality of several men of wealth, is exceptionally well provided with special laboratories, as well as with ordinary spacious and well equipped classrooms and laboratories for the instruction of students proceeding to medical degrees and diplomas in special and ordinary subjects. All the laboratory and other rooms are situated close to one another and intercommunicate, together forming large blocks of buildings. The work of students throughout all stages of their career is arranged upon very satisfactory lines, and the teaching hospitals, of which an account is given below, have amalgamated to form the clinical school of the university.

**Appointments.**—The nature of the appointments open to past and other students at this school will be gathered from the account which follows of the hospitals forming its clinical department.

**Scholarships.**—The awards made each year to successful students total over £1,500. They include the following: Two Holt Fellowships, one in Pathology, the other in Physiology; a Robert Gee Fellowship in Anatomy; two John Rankin Fellowships in Anatomy; a John W. Garrett International Fellowship in Bacteriology; a Johnston Colonial Fellowship in Biochemistry; an Ethel Boyce Fellowship in Gynaecology; and a Thelwall Thomas Fellowship in Surgical Pathology; one Lady Jones Fellowship in Orthopaedic Surgery (value of Fellowships: one at £200, three at £150, two at £120, four at £100); a University Scholarship of £50, awarded on the results of the Final M.B. (Part A) Examinations; a Scholarship in Mechanical Dentistry of £20; two Lyon Jones Scholarships, of the annual value of £21 each for two years, one for the junior and the other for the senior students; the Derby Exhibition of £15; the Clinical School Exhibition of £15; the Owen T. Williams Prize; the Torr Gold Medal in Anatomy; John Rankin Exhibition in Practical Anatomy, £25; the George Holt Medal in Physiology; the Kanthack Medal in Pathology; Mitchell Banks Medal in Anatomy; the Robert Gee Prize of £5 5s. in Children's Diseases; Mary Birrell Davies Memorial Scholarship (women), £60 per annum for four years; Robert Gee Entrance Scholarship (men), value of £40 per annum for four years; Dental Operating Prizes (four); Orthodontia Prizes (two); Samuels Memorial Scholarships, three at £20 each; one Thomas H. Bickerton Prize in Anatomy; Dr. N. E. Robert Prize in Zymotic Diseases; Ash's Prize in Dental Surgery, value £2 2s.; Gilmour Medal; and other entrance scholarships.

**Fees.**—Information as to the fees for the courses of instruction provided by the schools should be sought from the Dean of the Medical Faculty.

#### The Clinical School.

As many as ten hospitals have combined to form the clinical school of the university, these being: The Royal Infirmary, the David Lewis Northern Hospital, the Royal Southern Hospital, the Stanley Hospital, the Royal Liverpool Children's Hospital, the Hospital for Women (with the Samaritan Hospital), the Liverpool Maternity Hospital, the Eye and Ear Infirmary, St. Paul's Eye Hospital, and St. George's Hospital for Diseases of the Skin. Between them they provide about 1,445 beds.

#### MANCHESTER.

THE staff of the Medical School in this city constitutes the Medical Faculty of the Victoria University, all the arrangements for the instruction of students, both in their earlier and their later studies, being of an elaborate nature. The clinical work of the undergraduates is done chiefly in connexion with the Royal Infirmary, an institution which itself contains about 668 beds, and has associated with it a large convalescent home (132 beds), and the Mental Hospital at Prestwich. Instruction in practical gynaecology and midwifery is given at the Royal Infirmary and the St. Mary's Hospitals.

**Appointments.**—The following are among the appointments open to past and present students of this school in connexion with its arrangements for clinical tuition: One surgical registrar, at £150 per annum; two pathological registrars, at £100 and £50 per annum; one medical registrar, at £150 per annum; a cardiologist registrar, at £150 per annum; a surgical tutor, at £30 per annum; a director of the clinical laboratory, at £400 per annum, and two assistants, at £350; three assistant medical officers and three assistant surgical officers, each at £35 per annum; assistant surgical officer, aural department, at £35 per annum; seven anaesthetists, from £75 to £100 per annum each; one radiological registrar, at £250 per annum; one resident medical officer, one year, £200 per annum; ditto at Royal Lunatic Asylum, Cheadle, one year, £300 per annum; one resident surgical officer, one year, £200 per annum; two resident medical officers for Central Branch, £200 and £100 per annum; one assistant resident surgical officer, £150 per annum; one assistant medical officer at the Convalescent Hospital at Cheadle, appointed every six months, at a salary of £80 per annum; ten senior and ten junior house-surgeons and ten house-physicians, appointed during the year for a term of six months, at a salary of £50 for the first six months, and £100 for the second six months. Resident officers are appointed to the gynaecological, the eye, and the ear and throat departments every three months. Clinical clerks and surgical dressers are appointed to the various departments of the hospital every three months. Non-resident clinical assistantships for qualified medical women; tenable for six months, at an honorarium of £35.

SEPT. 4, 1926]

## WELSH NATIONAL SCHOOL OF MEDICINE.

**Entrance and other Scholarships.**—The following are among the scholarships obtainable by students of the school: Rogers and Seaton Scholarships in Arts (in alternate years), £40 per annum, tenable for two years. Derby Entrance Scholarship in Mathematics, tenable for one year, value £25, one being awarded annually, except in such years as a Cartwright Scholarship is awarded. Cartwright Scholarship, £35 per annum, tenable for three years. Three Hulme Scholarships, tenable for proficiency in subjects of three years. Three James Gaskill Scholarships of £35, one being awarded annually for general education. Two James Gaskill Scholarships of £35, tenable for two years, one being awarded annually for proficiency in the branches of mechanics and chemistry. A Dora Muir Scholarship, £30 per annum, tenable for three years, and open to the competition of women students only. This is awarded triennially. Sir J. P. Kay-Shuttleworth Scholarship, £30 per annum, tenable for three years, awarded triennially, open to the competition of scholars from Sedburgh School, Giggleswick School, and Burnley Grammar School; subjects—mathematics, chemistry, and mechanics. Dreschfeld Memorial Scholarship, value £20, tenable for two years and awarded triennially on the result of the Entrance Examination. John Russell Medical Entrance Scholarship, awarded annually, value £45. A Theodoros Modern Languages Exhibition, £20, awarded annually. Two Dauntsey Scholarships, value £45 and £35, tenable for one year, for students who have not commenced the second year of study leading to a medical qualification; subjects—zoology, botany, and chemistry. Two Entrance Scholarships in Public Health of £100, awarded annually. One Research Exhibition in Anatomy, £25, offered annually. Tom Jones Exhibition Scholarship of £90, tenable for one year. A Leech Fellowship of £100 for original research after graduation. A Graduate Scholarship in Medicine, value £25, tenable for one year, awarded annually for proficiency shown at Final M.B. Examination. A Dunville Surgical Prize, value £15, awarded annually at graduation. The Tom Jones Memorial Surgical Scholarship, value £60, tenable for one year, usually awarded for proficiency in certain subjects of the Final M.B., Ch.B. Examination. The John Henry Agnew Scholarship of £30, awarded annually for proficiency in the Diseases of Children. The Ashby Memorial Scholarship, value £20, offered triennially, for research in the Diseases of Children. The details and regulations of the Dickinson Scholarship in Surgery, and (4) Travelling Scholarship in Medicine—may be obtained from the Secretary to the Trustees. The Morrison Watson Fellowship for research in Anatomy is offered annually, value £150; also the Sheridan Delepine Fellowship in Preventive Medicine, value £300, is offered biennially. The Sam Gamble Scholarships—the trustees are prepared to award four scholarships of not less than £40 per annum, tenable for not more than four years, to women students who have passed the First M.B. Examination; the conditions can be obtained from the Registrar. The Knight Prize of £50 for original research in psychological factors in the causation of mental disorder—open to holders of the Diploma in Psychological Medicine or medical practitioners who have been registered in the university as candidates for that diploma.

**Fees.**—The composition fee for the university course in medicine is 110 guineas, payable in four instalments of 27½ guineas, but this sum does not include the fee to cover the work required for the First M.B. Examination. This is £42, payable in one sum. Hospital fees are additional, and usually amount to about 77 guineas.

A prospectus and further information about the school and scholarships may be obtained from the Registrar.

**Clinical Work.**—The Royal Eye Hospital, the Hospital for Diseases of the Skin, the Manchester Northern Hospital for Women and Children, and St. Mary's Hospitals for Women and Children, all make arrangements for the instruction of students.

## SHEFFIELD.

In this city the medical school is one of the departments of the university, being conducted and controlled by its Medical Faculty, and occupying practically the entire north wing of the quadrangle of the university buildings overlooking Weston Park. The laboratories and lecture rooms connected with the subjects of the first and second examinations—namely, chemistry, physics, biology, anatomy, and physiology—are, both as regards structural arrangement and scientific equipment, on the most modern and complete lines.

For students of pathology and bacteriology there are laboratories replete with everything necessary for the most advanced work, and a large pathological museum which is open daily. In addition, there is a museum devoted to materia medica specimens, and a large library and reading room. There are a number of recreation, athletic, and

other societies, all under the management of an annually elected students' representative council, and large and comfortable common rooms both for men and women students. There are also two student unions—one for men and one for women students. In the university buildings there is a refectory open to all students of the school, and a university journal is published each term. The ordinary clinical work of the school is done at the Royal Infirmary and Royal Hospital, which have amalgamated for the purpose of clinical instruction, and provide over 800 beds for medical, surgical, and special cases, including diseases of the eye.

In addition, the Royal Infirmary has special departments for the treatment of diseases of the skin and ear, with beds assigned to them; whilst at the Royal Hospital there are special out-patient departments for diseases of the throat, ear, skin, orthopaedics, and mental diseases. The medical and surgical staffs attend daily, and give clinical instruction in the wards and out-patient rooms. Clinical lectures in medicine and surgery are given weekly. Instruction in the practical administration of anaesthetics is given at either institution by the anaesthetists, and the post-mortem examinations at both institutions are in charge of the Professor of Pathology, and afford ample material for study of this subject. Students are able to attend the practice of the Jessop Hospital for Diseases of Women and the Hospital for Sick Children, while special courses on fever diseases at the South Yorkshire Mental Hospital, and on mental diseases at the City Fever Hospital, are given at the City Fever Hospital.
